Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," DEC. 29, 1905.

THE

ELECTRICAL ENGINEER

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOL. XXXVI. (NEW SERIES.)

FROM JULY 7, 1905, TO DECEMBER 29, 1905.

LONDON:

Printed and Published for the Proprietor by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court, Fleet-street, E.C.

1905.

Digitized by Google

INDEX TO VOL. XXXVI. (New Series.)

NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, 290) than the Notes and Business Notes, references to which are shown by light type (thus, 290).

A.

Abrasives, Artificial, 183
Academic Side of Technical Training, Prof. Kennedy, 16
Accidents, 64, 65, 104, 149, 173, 211, 246, 247, 318, 325, 354, 356, 427, 498, 493, 534, 567, 605, 710, 759, 857, 859, 924; also see "Tramway Cases" in LEGAL INTELLIGENCE

Accumulators, etc:
as Adjuncts to Central-Station Equipment, 706
Boosters, Controlling for, 472
and Boosters, Some Points relating to, L. Broekman, 842
E.P.S., 23, 53, 351, 643, 924
Locomotive, 377
for Operating Signals, 830
Questions and Answers, see QUESTIONS AND ANSWERS
for Traction, 125, 377
at Wednesbury Corporation Electricity Distributing Station, 880

Addresses, New or Change of, see "Removals"
Administrative County of London Power Bill, 3, 32, 40, 59, 91, 128, 165, 200, 220, 234
Aerial Power Lines, Notes on, Che, 191, 227, 256, 338
Agencies, 32, 212, 213, 248, 320, 464, 499, 643, 716, 751
Air Conductivity, 614
Air Friction on Trains, 147
Alexandria Exhibition, 469
Alloys, Low-Temperature Process for Making without Fusing Metals, 38
Alternate-Current Electrolysis, Prof. Wilson and W. R. Cooper, 369, 625
Alternate-Current Machinery at Olympia, P. R. Friedlaender, 474
Alternate-Current Machinery, W. Stanley and G. Faccioli, 309
Alternate-Current Transformers for Minimum Cost, Calculation of, Dr Pohl and H. Bohle, 446, 519
Alternating Arc, The Relation between Current and Voltage in, H. F. Simon, 561
Alternating-Current Rectifier, A New, 471
Alternating Currents, The Transmission of Power by, A. Still, 366, 452, 490, 559, 587, 621
Alternating and Direct Currents, Magnetization by, 111
Alternators, see DYNAMOS
American Apprentices, 217
Appointments, 612; also see "Personal"
Appointments Vacant, see each issue
Arc, Carbon, Residual E.M.F. of, 400

Arc Lamps:
Carbon Ends, Use for, 325
for Blue Printing, 441
B.T.-H., 634; Supplement, Sept. 8
Brockie-Pell, 23
Enclosed, 441
Excello, 441, 484
Flame, 441
Lewis, 441
Lowering Gear for, 60, 752
Midget, 441
at Olympia Exhibition, 441, 484
Oriflame, 441
Series Alternate-Current, 471
Starter for, 814
Steinmetz, 441
Twin-Carbon, 441

Artificial Draught for Boiler Plants, F. H. Davies, 193
Australian Trade Marks, 415
Automatic Cut-Outs, 545
Automobiles, 354, 355, 363, 498, 745
Awards (Exhibitions), 470, 644, 680, 896
Ayrton, Prof., The Distribution of Power, 409, 457

B.

Baker, A., Presidential Address before Municipal Tramways Association, 19

Balance-Sheets, etc.:
Aberdeen Accounts, 701

ELECTRICAL ENGINEER.

No. 1, Vol. XXXVI. LONDON, JULY 7, 1905. PRICE 3D.

NOTES.

Royal Institution.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon, Sir James Crichton-Browne, M.D., F.R.S., treasurer and vice president in the chair. Baroness Gray was elected a member. The special thanks of the members were returned to Sir Andrew Noble, K.C.B., F.R.S., for his donation of £100 to the fund for the promotion of experimental research at low temperatures, and to Mr. Rollo Appleyard for his gift of a portrait of the late Prof. J. D. Everett, F.R.S., M.R.I.

Wireless.—It is reported from Halifax (Nova Scotia) that wireless communication between Halifax and Sable Island has been established. It is also reported that the Anglo-American Cable Company will abandon its stations in Newfoundland on account of the Government tax and establish itself in North Sydney (Cape Breton Island). The Newfoundland Government propose to lay a cable to Canso (Nova Scotia), and there connect with the Canadian Pacific Telegraph Company's system in order to compete with the Anglo-American Company's local business. Arrangements have been made with the Commercial Cable Company for the laying of this cable.

New Publications.—"The Central": The volume, dated June, issued by the Central Technical College Old Students' Association contains articles on "Suction Gas Producers," by A. T. Larter; "The Manufacture of Acetone," by A. Marshall; "Glimpses of the Americans," by R. Seligman; "The Manufacture of Paper," by A. R. Reed; and others. There has been issued from the American Department of Commerce and Labour Nos. 1 and 2 of the *Bulletin* of the Bureau of Standards, which contain a number of interesting papers. Several of these are already known, having been read at the St. Louis Convention, but the volumes form an excellent collection.

Tramways and Light Railways Association.—In the official circular for June notice is given that Sir Herbert Jekyll, on behalf of the Board of Trade, has arranged to receive representatives of the Tramways and Light Railways Association and of the Municipal Tramways Association for the discussion of certain questions in regard to tramways—viz.: (1) the incidence of cost of guarding new Post Office wires crossing existing tramway lines; (2) the memorandum on details of construction and equipment issued by the Board in January, 1905; (3) the proposed monthly inspection of each separate insulator on the overhead equipment. The pamphlet also contains a paper by Mr. R. W. Western upon "The Rationale of Accounts," in which he deals with the subject of balance-sheets in a lucid style.

London Traffic Commission.—The report of the Royal Commission on London Traffic was signed on Monday of last week, and has been presented to the King. The text of the report is expected to be published in a day or two. Meantime it is understood that the Commissioners advocate the creation of a traffic board, whose special duty would be the consideration of all applications made by local and other authorities to street locomotion. This, it is held, will tend to create uniformity in the laying down of new lines, and at the same time obviate much of the inconvenience at present arising from the irregular and haphazard method of breaking up the London streets. The composition of this body would probably include "a man of affairs," a lawyer, and an engineer. Another recommendation of the Commissioners deals with the necessity for a comprehensive scheme of street widening, and the development and linking up of the existing tramway systems.

Trees as Antennæ.—We referred some time ago to the experiments conducted by Major G. O. Squier, of the United States Army, regarding the use of trees as antennæ in wireless telegraphic operations, particularly for military purposes. These experiments gave promise of considerable utility, and Major Squier, with the approval of the United States Government, has been extending them. The results appear to be distinctly favourable, as messages are stated to be readily received over a distance of 32 miles, using a very simple form of apparatus, which can be carried by a soldier on his person. As illustrating the facility with which communication is established the report of an officer in the Signal Corps is interesting. This states that as the messages were arriving with marked efficiency the officer suddenly changed the site of the receiving station to a spot 100 yards distant, and in three minutes fresh communication was established. Major Squier's tests suggest that for condensed news it is now possible to transmit messages from a central station to any number of other stations within a radius of 100 miles with very simple apparatus. It also promises to be of service for temporary installations, as the expense of erecting a permanent mast is disposed of. Although we gather that certain trees interposed between the points at which Major Squier conducted his tests, they do not seem to have caused any appreciable interference.

The Underground.—The fates were inimical to the District and Metropolitan Companies on Saturday, when the electrical services between Ealing and Whitechapel and on a portion of the Circle were due to be inaugurated. The trains started off well enough, but on approaching Hammersmith it was found that the torrential rains of the early morning had submerged the track and impaired the insulation of the conductor rail. These floods have often been a bugbear to the steam locomotives, and it was supposed that the improved drainage resulting from the pumping station lately erected in Lot's road by the County Council would have obviated repetitions of the nuisance; but presumably the downpour on this occasion was too heavy to be dealt with readily. Under the circumstances it was decided to give the steam-engines another show or the day, although on the Metropolitan portion of the Circle electric trains were running during Saturday afternoon.

Digitized by Google

Arrangements have, however, been made with a view to preventing a recurrence of the flooding, and the Ealing to Whitechapel electrical service was in satisfactory operation on Monday. In regard to the Inner Circle it appears that the collecting-shoe of the Metropolitan Company's rolling stock is not adapted to the District line. The District trains effect contact with the conductor rail by a 5in. shoe located midway between the extremities of the train, while the Metropolitan trains are equipped with a 3in. shoe at the end of every carriage. It was found that the pressure of the second shoe had displaced the conductor rail. It will therefore be necessary for the Metropolitan equipment to be altered in that respect before the through service over the District section of the Circle can be resumed.

The Tantalum Lamp.—In his paper read before the Denver meeting of the American National Electric Light Association, Dr. Louis Bell described some tests he had made with 10 25-Hefner 110-volt tantalum lamps. Amongst these we notice some stroboscopic tests to determine whether at, say, 25 cycles there was a specially violent fluctuation of light. These tests were decided upon on account of the initial resistance of the tantalum being low and the thermal inertia small, owing to its small mass and low specific heat, this being apt to conduce to rather violent heating up. The result of the tests showed that the light fluctuation at this frequency was somewhat but not much more pronounced than in a carbon filament. The lamp behaved, in fact, similarly to a 10-c.p. carbon-filament lamp. Even a 75-c p. carbon-filament lamp, however, shows perceptible variation under this test. At 60 cycles the fluctuation, while still perceptible, was trivial both in the tantalum and carbon lamps. It appears probable that the final break in the tantalum filament occurs just where one of the lamps has reduced the cross-section of the wire beside it. Placing aside questions of detail, the author sums up the position by stating that the results of the tests demonstrated that the tantalum type provides a *bona fide* two-watt lamp having a light fairly comparable with the carbon-filament lamps now in use. Moreover, it is a competitor with these socket by socket, and not as a substitute with particular requirements, as in the case of the Nernst lamp or very small arcs. There is some doubt as to the life of the tantalum lamp when exposed to unusual vibration, which may exclude it at present from special purposes; but for the every-day work of the central station it seem likely to be generally applicable.

Incorporated Municipal Electrical Association.—At the annual meeting of this association held in Edinburgh on Friday last, Mr. J. E. Edgcome (Kingston-on-Thames), the hon. secretary of the association, was unanimously elected president for 1906, and it was agreed that the conference next year should be held in London. The following gentlemen were also elected: Mr. S. E. Fedden (Sheffield) and Mr. C. D. Taite (Salford) as vice-presidents; Alderman G. Pearson (Bristol), hon. solicitor; Mr. J. H Rider (London), hon. treasurer; and Mr. H. Faraday Proctor (Bristol), hon. secretary. Of the retiring members of council, Alderman Bruce (Sunderland), Alderman E. Elvy Robb (Tunbridge Wells), Alderman J. P. Smith (Barrow-in-Furness), Bailie Willock (Glasgow), and Councillor Sinclair (Swansea) were re-elected, and the remaining vacancies were filled by Mr. R. A. Chattock (Birmingham), Mr. W. Lackie (Glasgow), and Mr. Day (Bolton). The question of loans for electricity supply purposes was then discussed, and the following resolution passed: "That this meeting views with serious apprehension the recent action of the Local Government Board in reducing the already short periods allowed for the repayment of loans for electricity undertakings, and is convinced that such alteration is not only unnecessary, but threatens seriously to handicap legitimate municipal enterprise; it therefore enters its protest against the very short period now being allowed, and hereby empowers the council to take such steps as they may think necessary to bring about a more equitable and uniform treatment." Twenty-five years is the minimum period desired. Votes of thanks were passed to the Corporations of Edinburgh, Glasgow, and Aberdeen for their hospitality, and to Mr. Newington for his labours as president.

The Institution —The annual conversazione was held at the Natural History Museum, South Kensington, on the 29th ult., when over 1,400 guests were received by the President and Mrs. Siemens and the President-Elect and Mrs. Gavey. Numbered among them were: the Hon. Sir W. Arbuckle, Mr. J. Ardron, Sir A. R. Binnie, Colonel G. F. O. Boughey, R.E., C.S.I., Sir D. Brandis, the Hon. Sir H. B. Buckley, Prof. H. L. Callendar, F.R.S., Mr. T. O. Callender, Mr. A. Campbell, Mr. W. G. Cavendish-Bentinck, Sir C. P. Clarke, C.I.E., Captain E. W. Creak, R.N., F.R.S., Sir W. Crookes, Mr. W. Duddell, Mr. S. Z. de Ferranti, Mr. R. K. Gray, the Hon. W. C. Gully, Mr. Robert Hammond, Mr. C. Hawksley, Mr. J. S. Highfield, Mr. Hugo Hirst, Sir R. Hunter, Captain H B. Jackson, R.N., F.R.S, Mr. J. E. Kingsbury, Sir J. N. Lockyer, K.C.B., F.R.S, Sir H. C. Mance, C.I.E., Mr. W. M. Mordey, Sir H. T. Maxim, the Hon. Richard Oliver, Major W. A. O'Meara, R.E., C.M.G., Mr. W. H. Patchell, Mr. S L. Pearce, Prof. J. Perry, F.R.S., Sir W. H. Preece, K.C.B., F.R.S., Sir W. Shelford, K.C.M.G., Mr. H. Babington Smith, C.S.I., Mr. C. E. Spagnoletti, Lord Strathcona and Mount Royal, G.C.M.G., Sir J. W. Swan, F.R.S., Mr. Jas. Swinburne, Prof. S. P. Thompson, F.R.S., Sir J. I. Thornycroft, F.R.S., Major-General Sir A. Turner, K.C.B, Prof. W. C. Unwin, F.R.S., Mr. R. W. Wallace, K.C., Mr. A. J. Walter, Colonel Sir C. M. Watson, K.C.M.G., C.B., Mr. C. H. Wordingham. A varied musical programme was rendered by the string band of the Royal Engineers and the Leoni Ladies' Quintette, and altogether a highly agreeable evening was spent. In the Reptile Gallery the visitors had the privilege of beholding a gigantic specimen of the Diplodocus Carnegii, which created mingled admiration and awe. It is to be regretted that the date of the conversazione again coincided with the annual convention of the Municipal Electrical Association. This prevented practically all municipal engineers from attending the conversazione, and rendered it a less representative gathering.

Selective Wireless Telegraphy.—A demonstration was given last week by Mr. A. T. M. Johnson at West Kensington of his system of selective wireless telegraphy and telephony, which he has christened the Johnson Multitonophic system, and of which a description has already appeared in this journal. The inventor claims that by the use of his selective reed interception of messages is impossible. A miniature sea was provided in the garden, and a room at the rear of the house was fitted up as a transmitting station, a small shed at the opposite end of the garden being utilised as a receiving station. The transmitting apparatus used on this occasion consisted of a Ruhmkorff coil, on the base-plate of which was mounted a multitonophonic reed disc, supported on a sliding pillar. To the reed disc armatures with suitably weighted heads were attached, in proximity to which tuning reeds were adjusted, electric contact being effected in the usual manner. The receiving instruments consisted of permanent magnets situated in metallic cases, the action of the permanent magnets being increased by the aid of electromagnets suitably adjusted, immediately above which steel reeds, tuned in unison or octaves to those situated on the trans-

Digitized by Google

mitting disc, were secured. The operator revolves the reed disc of the transmitter until both the tuning reed and its accompanying speaking reed are situated immediately in front of the centre core or cores of the electromagnet. He then turns the screw of the contact pillar until the end touches the platinum contact in the speaking reed, closes the circuit by turning the commutator to the right or left, and turns the contact screw backwards or forwards till the speaking reed synchronously causes the tuning reed, which is the indicator, to vibrate also. When the tuning or indicating reed vibrates the operator knows that the receiving station with a similarly tuned reed is getting the message through, as it is compelled to vibrate in unison by the law of syntonic synchronism. The object of the tuning or indicating reed is to show the operator whether the reed at the receiving station is acting or not. The responses obtained last Friday with the experimental apparatus, both in regard to telegraphy and telephony, were fairly satisfactory, and we shall await with interest the result of the operations which we understand are about to be conducted on a practical scale at sea.

The Administrative County of London Bill.—The debate on the second reading of this Bill in the House of Commons was expected to take place last night, and recent incidents suggest that the proceedings were of a lively character. The promoters feel aggrieved, and not altogether without reason, at the action of the London County Council in addressing metropolitan M.P.'s, urging them to vote against the measure and so dispose of it at an early stage, instead of the matter being investigated in committee. In their circular letter the Council gave a list of objections to the scheme, and in response to this the promoters forwarded a letter of protest to the Council, accompanied by categorical replies to the latter's objections. Amongst these the company state that their scheme would break a vast quantity of new ground, instead of interfering with the existing undertakings. It is pointed out that the maximum prices chargeable are lower by half than the average prices at present ruling in the Metropolis for power, and that the charges are subject to revision by the Board of Trade. In response to the Council's assertion that the case for the Bill is based entirely upon estimates of what the company will be doing in 1910, and to a large extent ignores the fact that the existing electrical undertakers are making strenuous endeavours to develop their business, the company reply that they have undertaken to set to work on the Bill being passed, and that their low prices would come into immediate operation. While acknowledging the endeavours of the existing undertakings to increase their field, the company point out that their efforts have only resulted in securing 4 per cent. of the total power used in the industrial district, and state that the promoters of the Bill would enable the existing companies, by sharing the benefits of concentration, to develop power supply without further capital outlay. Regarding the fact that the Bill does not contain a purchase clause, the promoters point out that the Legislature, when framing the enactment relating to electric lighting, did not contemplate making such a provision in the case of power companies. Reference is also made to the fact that the County Council did not call a single witness in support of their contentions when the matter was before the Lords Committee. The document concludes by emphasising the great benefit to the community which would result from a cheap power supply. Taken all round, the promoters at least make out a case for a reference to committee so that the merits of the scheme may be thoroughly threshed out. We understand that the company have already entered into a number of provisional contracts with local authorities.

Birthday Honours.—The list of honours issued last week in celebration of his Majesty's birthday shows that Lord Rayleigh is to be created a privy councillor. His lordship's achievements are so well known that nothing remains but to congratulate him. Knighthoods are bestowed upon Prof. A. B. W. Kennedy, Mr. J. Clifton Robinson, and Mr. J. C. Lamb. Quite apart from the good work which Sir Alexander Kennedy has done in connection with the University College, he for years has been looked up to as a leading consulting engineer on electrical matters. He has been responsible for the design and management of many of the most successful electrical supply undertakings, and did most valuable pioneering work as the engineer-in-chief of the Westminster Electric Supply Corporation. His work in connection with the London County Council tramways is also well known, and he was responsible for the electrical equipment of a number of the tube railways. His work in this respect now includes an important equipment for the Great Western Railway, which is expected to be the beginning of a large electrification scheme. No doubt Prof. Kennedy's work for the Admiralty in connection with the historic boiler trials is also recognised in the honour conferred upon him, which is highly appreciated by all electrical engineers. He is a Fellow of the Royal Society, and in 1894 the University of Glasgow conferred upon him the honorary degree of doctor of laws. How the London United Tramways have progressed and become a great public boon under Mr. Robinson's management needs no recapitulation. His work also in connection with the Bristol tramways and other large undertakings is marked by an individuality which few engineers can equal. Mr. J. C. Lamb receives the well-merited honour of knighthood in recognition of his valuable services at the Post Office. He was, in fact, engaged in this department ever since the telegraph system was transferred to the State, and assisted in the accountancy side of the transfer. He was one of the British delegates to the Submarine Cables Protection Conferences held in Paris in May and December, 1886, and in 1889 he was appointed assistant secretary to the Post Office. Subsequently he participated in several international conferences, and was appointed a Royal Commissioner on electrical communication with lighthouses and lightships. He organised the trunk telephone system of the Post Office, and conducted the purchase of the lines from the company. In 1896 he became third secretary to the Post Office, and in 1897 second secretary. Honours have been conferred upon him by foreign Governments.

The National Physical Laboratory.—A meeting was held on Tuesday afternoon at the House of Commons to consider the question of obtaining increased State aid for the National Physical Laboratory. Mr. R. B. Haldane, K.C., took the chair, and others present were Mr. A. Chamberlain, Sir R. Jebb, and Dr. Glazebrook. Mr. Haldane, in introducing the subject, explained that the laboratory, which was only supported by the State to a very small extent, was doing valuable work. Its object was to place the highest science at the disposal of the technical industries. The scientific knowledge and skill required was such that it was beyond the reach of the individual manufacturer, and he must look to some great organisation supported by the State to provide it. The National Physical Laboratory at Teddington was of immense use in the direction of testing in a scientific manner the products of industry, o carrying out experiments for manufacturers, of undertaking enquiries designed to obtain accurate standards, and dealing with scientific problems by which new processes might be developed. Its equipment was of the best, and the most eminent men were engaged in the work which was being carried on. Dr. Glazebrook, as director of the laboratory,

Digitized by Google

gave an account of its aims and working, remarking that in this respect we were far behind the Germans, who not only realised the advantages of science, but endeavoured in every possible way to apply that science to the most modern industrial developments. English agencies, on the other hand, were imperfectly supported, or the machinery placed at their disposal was found to be hopelessly inadequate. Mr. Chamberlain remarked that in his judgment the great educational problem of the future was not how to improve our elementary or even our secondary, but how to deal with our highest education. Looked at purely as an investment, it was from higher education that we should gain the largest return. The National Physical Laboratory was performing a most valuable service, but it appeared to him that the modern universities were doing much the same kind of work. He was all in favour of State aid for any such institution, and quite agreed that the amount at present accorded was far too little, but he suggested that the best plan would be for the various bodies to make a united application to the Government. The following resolution was then adopted unanimously: "That this meeting, being satisfied of the necessity of further State aid to the National Physical Laboratory at Teddington, as regards both equipment and maintenance, requests the chairman and convenors of this meeting to prepare and present a memorial to the Chancellor of the Exchequer asking for such additional aid, and that the memorial be signed by the members here present, or who, being absent, may be in sympathy with its object."

Electric Cars versus Motor 'Buses.—At the Municipal Tramway Conference on Wednesday, Mr. W. A. Luntley, of the Wolverhampton Corporation tramways, made a contribution to the electric tram *versus* motor-'bus question, his paper, though comparatively brief, containing an excellent review of the general position. He approached the subject from two aspects—cost and quality of service. The usual difficulty confronted him in obtaining statistics as to the motor 'bus, few figures being yet available. Following expert opinion, he estimates the working charges, including depreciation at about 20 per cent., to be quite 11½d. per mile, and quotes an instance where the figure reached 1s. 6d. Taking the average working cost of the electric car at 9¾d. per mile, he shows a substantial margin in favour of the latter. Regarding maintenance and renewal of tyres, which is such a heavy item in the motor-'bus account, he remarks that the original cost of something over 2d. per mile has been reduced by the makers guaranteeing the life of the tyre, but he also points out that this arrangement may not last. Then, in regard to petrol, he suggests that the enormous quantity now being consumed may have the effect of enhancing the price, so that the motor-'bus proprietor is threatened with trouble in regard to two most important factors. Another point that Mr. Luntley directed attention to was the allowance for depreciation. This has generally been assumed at about 20 per cent., but with the rough work the 'buses will be called upon to perform Mr. Luntley thinks this figure may prove inadequate, especially as the vehicles are not so substantially constructed as trams. Regarding capacity, he emphasises the fact that a bogie car has almost double the accommodation of a motor 'bus, so that the earning power of the latter would be relatively smaller, and it would be necessary to proportionately increase the number of 'buses to cope with the traffic. Touching upon the reliability of the two services, Mr. Luntley, while agreeing that it is early to pronounce an opinion regarding the motor 'bus, indicates that the complicated mechanism of the latter renders it more susceptible to breakdowns. In regard to speed, the author considers that, though the motor 'bus may score in narrow thoroughfares owing to its elasticity, the tram will show a better average result. He also predicts that the tram will have the better of it in respect of accidents, as skidding on a greasy rail may be more than counterbalanced in the case of the motor 'bus by side-skids, over which there seems to be no control. The author sums up much on the lines of the leading article we published on this subject a few months ago, as, while he recognises that the motor 'bus has a most useful sphere of influence in catering for districts where the traffic is not decidedly heavy, he holds that the electric tram possesses distinct advantages in thickly-populated localities.

Municipal Trading—Lord Avebury's remarks on municipal trading before the Industrial Freedom League on the 30th ult. were prefaced by a general statement that "the portentous and rapidly-growing increase both of municipal and national expenditure has roused the anxiety of all thoughtful citizens." He illustrated his point by the London County Council's tramway system, concerning which he said "that the Council, having secured a most valuable property far below its real value, it would have been difficult not to make a profit. The profit had amounted to £293,000, but, as Sir Melvill Beachcroft had pointed out, over £200,000 had been received from the northern system under the lease, while the southern system, worked by the Council, had given only £80,000, and last year the profit claimed on the southern system was only £7,054 on a capital of £2,400,000. It seemed clear that if the London County Council had leased the southern system, instead of working it themselves, there would have been an advantage of over £120,000 to the London ratepayers. If the County Council had not prevented private enterprise from undertaking the operation of the tramways, but had granted facilities under stringent regulations as to the proper conduct of the service, the ratepayers would have profited by the arrangement without being involved in any risk, and the load of debt now incurred would not have stood in the way of other improvements." It is not the first time that Lord Avebury has commented upon the County Council's tramways, and each time he has done so he has judged the success of the undertaking by the profits that have been made. We pointed out before, and do so again now, that this method of comparison between company and municipal management is quite a fallacious one. In fact, Lord Avebury himself emphasises this by a statement further on in his address with reference to the Manchester gas undertaking. He said it had been claimed that Manchester reduced its rates in 1900-01 by 7d. in the £ through municipal trading. This was how it was done. The Corporation wanted a subsidy of £50,000 in relief of rates from the gas undertaking, and as there was no surplus, the price of gas was raised 3d. per 1,000ft. in order to yield it. This was quoted as a profit. It is clear from this that an increase in price to obtain a profit is deprecated by Lord Avebury, and yet he condemns the management of the London County Council tramways because they have so reduced the fares and increased the remuneration of drivers and conductors that the trams are worked without making a large profit. It is rather the value of the actual service rendered by a municipal undertaking than to the undistributed profit that attention should be drawn. At the recent meeting of the Municipal Electrical Association at Edinburgh the Lord Provost of Glasgow was most emphatic on this point, and deprecated any municipal undertaking making a profit for the reduction of rates.

London's "Charlottenburg."—A little while ago there was some apprehension as to the progress of the

Digitized by Google

scheme for establishing a British technical foundation on the lines of Charlottenburg. The committee appointed by Lord Londonderry have just issued a preliminary report, which is prefaced by the observation that: "In considering the problem laid before us by the Government, we are impressed by the fact that the most urgent need in scientific education is the establishment of a centre in which the specialisation of the various branches of study and the equipment for the most advanced training and research should be such as ultimately to make it the chief technical school of the Empire." The report proceeds to state that it has evolved a comprehensive scheme for the purpose, but as private co-operation is essential to its realisation a series of preliminary conclusions have been formulated. If the various suggestions are found to meet with support, the committee anticipate that they will then be able to rapidly design a definite scheme. The conditions held to be necessary to the success of the project are as follows: "(1) The gift of a large capital sum (say not less than £100,000) for buildings and initial equipment; (2) the gift of a considerable additional site (say not less than four acres) at South Kensington; (3) the willingness of the Board of Education to allow their college at South Kensington to be brought into a scheme of common government and administration; (4) the similar willingness of the City and Guilds of London Institute in respect of their college at South Kensington; (5) the continuance of the Government contribution, including the necessary provision for the maintenance of the new laboratories and other buildings of the Royal College of Science, now approaching completion; (6) the continuance of the support given by the Corporation and livery companies of the city of London to the Central Technical Collge; (7) the provision (in the proposed College of Applied Science at South Kensington) of instruction is certain departments of engineering either by new foundation or by transfer and enlargement of part of the work of some existing college or colleges—*e.g.*, University College or King's College; (8) the co operation of the University of London; (9) the assurance of a sufficient maintenance fund." The committee then express confidence that private munificence will be prepared to provide a capital sum in excess of the minimum which the committee consider necessary, and that the additional site will also be forthcoming. The Board of Education have already announced their willingness to allow the Royal College of Science (including the Royal School of Mines) to be brought into the scheme under a common government and administration, and Lord Londonderry recently signified that the Chancellor of the Exchequer would probably see his way to extend financial support to the proposed institution. Several general suggestions are made as to the functions of the new institution, and the importance of a fully equipped school of mines is emphasised. The proposals are more or less in the embryonic stage at present, but the committee intimate that the scheme in view may be expected to result in the "establishment of an institution which will be pre eminent in its combination of advanced teaching in certain branches of applied science, with instruction in pure science also developed to a very high standard." The auguries now seem favourable to the realisation of a scheme which will provide Britain with a technical university that will compare with any foundation in the world, and the combination of State and private enterprise indicated above strikes us as a decidedly happy one.

The Telephone Transfer.—On the resumption of this enquiry on Monday by a committee of the House of Committee the municipal witnesses had another innings. Mr. H. E. Haward, comptroller of the London County Council, while admitting the force of the Post Office contention that without this agreement the company would be able to dictate terms in 1911, pointed out that the company would have been in a much greater difficulty by being in possession of property useless as a going concern to anyone but the Post Office. Moreover, the Post Office had the alternative of estaliahing at once a system which should between now and 1911 compete with the company either by way of unrestricted competition or limited competition, as it now prevailed in the London area, and in 1911 be ready to take over the company's subscribers. There would have been difficulties in the adoption of this course, but the Post Office would after 1911 have been in possession of a more modern and better equipped undertaking than would be probable if it purchased the company's plant and equipment. No evidence had been given to show that the Post Office would effect any substantial saving in purchasing the company's undertaking in the manner proposed, instead of establishing a new system. He considered that the agreement treated the company too liberally, and that the conditions of sale were not really mere "tramway terms." Mr. A. C. Morton, chairman of the Streets Committee of the Corporation of London, held that in order to justify the agreement it should be demonstrated that it would result in a thoroughly efficient service at a much reduced rate. Under such circumstances he should favour the transfer, but he had not heard any evidence that would encourage such a belief. Sir Wollaston Knocker, town clerk of Dover, stated the position of the Association of (non-telephone owning) Corporations, which through its Law Committee had passed a resolution approving of the Government's proposal, with a view to the early reduction of telephone charges, but urged that the Postmaster-General should make all necessary provision for safeguarding the general interests of municipalities with regard to wayleaves and to the breaking up of streets. On Tuesday Mr. W. E. L. Gaine, general manager of the National Telephone Company, was recalled, and replied to the case put forward on behalf of the municipalities owning telephonic systems. He alluded to the views of various witnesses that the company should be prevented from undercutting rates. But in every instance, he stated, the corporations had started undercutting by offering the service at lower rates than the company's. He condemned the internal plant employed in the municipal systems as being without exception obsolete. Dealing with the main claims put forward in behalf of the municipalities, he asserted that it was not open to the Postmaster-General to renew a municipal license and not at the same time renew the company's license in the same area. With regard to the claim of the municipal witnesses to local intercommunication between the company's system and those of the competing corporations, and that terminal fees should be abolished, he submitted that neither claim could be given effect to without disturbing parliamentary contracts. Competition in the telephone service was impossible if regard was to be had to efficiency and economy of working. In regard to the question of friction between competing local authorities, he stated that many difficulties would arise from the fact that in almost every case the telephone area comprised a large number of local authorities, the Manchester telephone area, for example, comprising the districts, in whole or in part, of 38 separate local authorities. As to the question of tariffs, he remarked that no comparison was of much value unless the local conditions were carefully examined and regard was had to the monetary standards of value in the various countries. Mr. John Gavey, engineer-in-chief to the Post Office, then gave his views in regard to technical questions that had arisen.

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

(*Concluded from page 913, Vol. XXXV.*)

WEDNESDAY, JUNE 28.

The second day of the convention involved a visit to Glasgow, where the members were welcomed by the Lord Provost (Sir John Ure Primrose) and the convener of the Electricity Committee (Bailie Willock).

The LORD PROVOST, in his speech, referred to past achievements in electrical engineering as wonderful, but thought we were at the day dawn of further progress. Electric power distribution would do much to purify the atmosphere and render factories possible in semi-rural districts. After a few remarks on municipal trading, he said that the sure way not to succeed was to depreciate the value of municipal service. He thought that the rewards offered by municipalities to those controlling their undertakings should be such as to attract the best men in commercial circles.

Bailie WILLOCK also welcomed the convention to Glasgow, after which a hearty vote of thanks was passed to these two gentlemen on the motion of the president.

Mr. HAMILTON KILGOUR, before reading the following paper, regretted that owing to ill-health the same was not completed. He also acknowledged the great help Mr. Faraday Proctor had rendered him in the preparation of the same.

Notes on Costs and Tariffs for Electric Supply.

BY HAMILTON KILGOUR, CHIEF ELECTRICAL ENGINEER, CHELTENHAM.

When an electric supply undertaking has but a single class of customers, as was generally the case a few years ago, a comparatively simple analysis of the costs of supply is all that is necessary in order to determine upon a suitable tariff; nowadays, however, most electric supply undertakings have at least two distinct classes of customers, and some have as many as four, with the result that a more detailed analysis of costs is essential if an appropriate tariff is to be established for each class. Some 12 months ago somewhat extensive inquiries were made as to the scales of charges obtaining in various towns for energy supplied for traction and as to the governing conditions which determined the agreed upon scales, and, through the kindness of brother engineers, a considerable amount of useful and instructive information was obtained. A study of the data disclosed not merely very considerable differences between the tariffs, which was quite natural, but also very considerable differences of opinion among engineers as to the proper allocations of the costs of supply as between, for instance, traction and general supply; and several engineers suggested, or acquiesced in the suggestion, that a meeting of those interested in traction supply should be held in order that a general interchange of ideas *re* traction cost allocations and tariffs should take place; it was, however, found impracticable to arrange for this last year.

The annual convention of the I.M.E.A. offers an eminently suitable opportunity for the discussion of such a subject as "cost allocations and tariffs," because, although certain important premises depend on purely technical bases, others—equally important—and the deductions to be made from all the premises depend on purely business considerations—thus, the subject is one for discussion by committee delegates quite as much as by engineers. Several very interesting and useful papers on costs of supply, tariffs, and methods of charging have been contributed from time to time by members of this association: but, mindful of the adage, *Omnia mutantur, nos et mutamur in illis*, and of the vital importance of the subject to all concerned with the management of electric supply undertakings, the submission of another paper is thought justified, and these notes have, therefore, been written in the hope that a full and useful discussion may result therefrom. To every student of the relation between costs and tariffs the question, "On what do costs of supply mainly depend?" will inevitably present itself at an early stage; and a knowledge of the correct answer, together with a proper understanding of all that the answer connotes, is an essential preliminary to any further (useful) study of the matter. The correct answer to the foregoing question is, "Costs of supply depend, in general, almost entirely upon the liabilities undertaken, and but little upon the actual supply given." The liabilities undertaken are twofold in character, since acceptance of anyone as a customer renders it obligatory to provide the necessary plant, mains, etc., for giving him supply at the greatest rate he chooses to name in his application, and also to so run the plant that the customer may have supply as and when he requires it—subject only to his not exceeding the rate of supply applied for as a maximum.

The capital expenditure upon an electric supply undertaking is, of course, absolutely determined by the total liabilities undertaken, or thought to have been undertaken, by the acceptance of customers; hence all annual charges upon capital, whether compulsory or optional, are similarly determined and are quite independent of whether supply is, or is not, actually given to customers. The compulsory annual charges are those for interest and sinking fund, and the optional those for insurances in respect to property. The revenue expenditure* of an electric supply undertaking, or its annual cost as a going concern, is obviously divisible into two distinct parts—viz., that dependent upon the liability undertaken to give supply as and when required by the customers, and that dependent upon the extent to which customers avail themselves of their opportunities for taking supply; these two kinds of costs are often called the "cost of getting ready to give supply" and the "running cost" respectively, and the former plus the annual charges on capital is usually called the "stand-by cost." No one of these three terms is very aptly descriptive of the cost to which it refers, but pending agreement as to a more appropriate nomenclature, it will be convenient to employ them. The "cost of getting ready to give supply" clearly includes all costs of distribution, of meter reading and maintenance, and of management (in fact, all costs except those of rates and taxes and of labour and materials employed at the works), since these solely depend upon the number and kinds of customers connected, and upon their topographical distribution; it is indisputable also that a part of the works' costs is due to the undertakers' obligation to be always ready to give supply, *i.e.*, to have an adequate quantity of machinery running and an adequate number of men on duty at every moment of every day. The quantity of plant (boilers, engines, dynamos, and auxiliaries) in use, and the quantity of labour in attendance thereon, at any particular instant in a works are determined entirely by the expectation of load proper to that instant; if the expectation is realised energy will be supplied, and coal and water used, at certain rates; if the expectation is not fully realised energy will be supplied, and coal and water used, at less rates; and in the extreme case of the expectation being wholly falsified by the load falling to zero, no energy will be supplied, and coal and water will be used at the minimum rates consistent with adequate provision for coping with the expected load. As regards items of expenditure other than those for labour (attendance and supervision), coal and water, it makes, in general, very little difference whether the expectation of load is fully realised or wholly falsified, or, in other words, whether the plant runs loaded or light, according to a given time-table of use. The effect of a load may be to slightly increase the quantities of oil and sundries used, the quantity of boiler scale formed, and the repairs and maintenance required; but since the total costs of these items are small compared with the total costs of labour and coal, small variations in them may be regarded as unimportant, especially in cases of bad load factor.

The usual method of ascertaining the average value of the "running cost" per unit generated is to subtract the total works cost of the six light-load months from the total works cost of the six heavy-load months, and to divide the remainder by the difference in the numbers of units generated in these two periods; not infrequently and more properly, as appears from what has been already stated, engineers take for this purpose the costs of coal and water alone instead of the total works' costs. Each of these two methods will usually give too large a value for the "running cost" aforesaid, in spite of the fact that in most works plant is run under less economical condition—*i.e.*, at lower average plant load factors—during the six light-load months than during the six heavy-load months. For works in which it is customary to make periodic steam consumption tests on each unit of plant (including auxiliaries), and in which the coal required per hour is known (approximately) for each boiler (*a*) at full steam pressure—stop valve closed, (*b*) banked; the average value of the "running cost" per unit generated can be obtained directly from the performance records (log sheets or summaries of them) of the various units of plant. In a modern works with fairly large units the average value of the "running cost" per unit generated should not exceed ½d., unless the circumstances are peculiarly adverse. At the Cheltenham works, which have been running for more than 10 years, and which have rather small units in consequence of both alternating and continuous current supply being given, the average value of the "running cost" per unit generated in a certain year was 0·25d. according to the second method of estimation described, and 0·23d. according to the third; the author believes the latter value to be the more nearly correct.

* Exclusive of that incurred for and reimbursed by customers on account of materials and labour supplied for their installations; this expenditure includes that for carbons, trimming, etc., of street lamps, which are virtually installations belonging to the public lighting authority.

Digitized by Google

The works' "cost of getting (or keeping) ready to give supply" during a particular period is, of course, the difference between the total works' costs for that period and the total "running cost" of the energy generated therein; in general, it will be found that the ratio of the works' "cost of getting ready to give supply" to the total works' "running cost" for any year ranges from about 3 to 1 for a bad load factor and a small output, up to about 1 to 1 for a very good load factor and a fairly large output. The total "cost of getting ready to give supply" is, as stated earlier, the corresponding works' cost plus the costs of distribution, of meter reading and maintenance, and of management; and the "stand-by cost" is the total "cost of getting ready to give supply" plus the charges on capital. It is, therefore, obvious that the "stand-by cost" of an undertaking must, in general, be very much larger than its total "running cost." The annual charges against an undertaking for rates and taxes are totally different in character from any of the costs and charges previously considered. Thus, local rates are supposed to be proportional to the rent a hypothetical tenant would be willing to pay for the undertaking, and income tax is proportional to the gross profit less an allowance for depreciation. Virtually, therefore, both rates and taxes depend on the actual, or—as the case may be—the presumably possible trading results, and should be regarded as first charges upon the profits rather than as elements in the cost of working: for this reason it appears not merely convenient, but also correct to take no account of them when considering costs—they have, of course, to be allowed for when settling tariffs.

With reference to the undertaking as a whole—and so far this aspect of it has alone been considered—the conclusions arrived at may be summarised as follows: (1) The total annual costs are divisible into two distinct parts—(*a*) "stand-by costs," or costs entirely dependent upon liabilities; (*b*) "running costs," or costs entirely dependent upon the quantity of energy actually generated. (2) The profits of the undertaking are subject to an annual charge for rates and taxes, and should, therefore, be at least sufficient to defray this charge. In general it is quite impossible to ascertain precisely the actual cost of the supply given in any particular year to any particular customer; and were it possible to ascertain the supply cost of every single customer of an undertaking, the expense of the work involved would be prohibitive. It follows, therefore, that it is quite impracticable to frame a tariff which is equitable in the sense that it will ensure that every customer is charged his supply cost plus a fixed percentage. If, however, the customers be grouped into a few distinct classes, each with well-defined characteristics in respect to the liabilities of the undertaking towards it, and different supply costs of the different classes can often be approximately ascertained, and a tariff, or set of tariffs, can be determined which will ensure that each class pays its supply cost plus the same percentage. The tariff for each class may take the form of a flat rate, which has the great advantage of simplicity and the great disadvantage of discouraging the profitable and encouraging the unprofitable customers, or of a sliding scale based, for instance, on either the Hopkinson or the Wright system.

Every method by which it is sought to divide the total annual costs of an undertaking equitably among certain different classes of customers must comprise three principal operations—viz., (1) the allocation of the energy wasted in distribution, and of the energy used in the works, offices, etc., between the different classes of customers, so that the number of units *generated* for each class—and, therefrom, its total "running cost"—may be known; (2) the allocation of the total capital expenditure between the different classes of customers so that the annual capital charge proper to each may be known; (3) the allocation of the total "cost of getting ready to give supply between the different classes of customers." And when these allocations have been more or less satisfactorily made, it remains to allocate the annual charge for rates and taxes. Now, each of the three operations mentioned may be regarded as comprising two subsidiary and distinct operations—viz., the allocation of energy wasted or used, or, as the case may be, of cost incurred, specifically in connection with a particular class of customers, and the allocation of energy wasted or used, or of cost incurred, without special relation to any particular class; the former kind of allocation is simple and generally quite easy, the latter is very difficult and sometimes exceedingly laborious.

Until comparatively recently the author thought, as he believes many do still, that it was desirable to attempt an equitable allocation of the total annual costs of an undertaking between such different classes of customers as those taking electric supply of private lighting, motors, public lighting, and traction; also, that by comparing the allocated cost of each class with the income derived from it some useful conclusions might be arrived at; he has since become convinced, however, that equity has nothing to do with the matter. The proper way of viewing the question is to recognise that the total annual costs of an undertaking include a general establishment charge besides the actual annual costs of the different classes of customers—the actual annual cost of any given class of customer being defined as the amount by which the total annual cost of the undertaking would have been less had the class of customers never existed and had no provision, therefore, been made for giving supply to it. It is necessary to add that, under certain circumstances, the actual annual cost (as before defined) of a particular class of customers may increase abnormally—that is to say, the precise duplication of every individual customer may cause the actual annual cost of the class to be more than doubled; for instance, at a particular epoch in an undertaking's history it may easily happen that, had a certain class of customers never existed, the capital expenditure (and, as a consequence, the capital charges) would not have been less to any appreciable extent, and, therefore, that the actual annual cost for the said class of customers may be surprisingly small. It may also happen that at the epoch considered it may be possible to distribute the bulk of the general establishment charges among the other classes of customers, and so to offer specially favourable terms to a particular class without immediate loss resulting therefrom. Now it is not unlikely that the favoured class of customers will grow at a much more rapid rate than the remaining classes, and it is possible that it may become more important (in respect to its use of energy and to its maximum rate of use of energy) than all the other customers taken together, with the result that the actual annual cost of this class may increase very considerably, and, unless the tariff be revised, may lead to supply being given at an absolute loss. The moral is that not merely the actual annual costs of the present, but also those reasonably probable in the future, should be considered when settling tariffs and the reference is to day-load (motor) customers.

Just as the total annual cost of an undertaking is influenced mainly by the liabilities undertaken for giving supply as and when the customers generally require it, so in regard to any particular class of customers the cost of supply is mainly determined by the liabilities assumed with respect to it, and it may be well to briefly discuss now some of the characteristics in regard to liabilities of the four classes of customers previously mentioned—viz., those for private lighting, motors, public lighting, and traction. The liability of an undertaking towards an individual customer or towards a class of customer depends on (1) the maximum demand—possible and probable; (2) the time or times at which the maximum demand occurs; (3) the duration of the maximum demand or of a demand nearly equal to the maximum; (4) the degree of knowledge possible with reference to the variations of the demand with time; and (5) the periods, if any, during which supply may be discontinued. In the case of ordinary customers for lighting experience has proved that the maximum demand, or greatest actual rate of supply, of almost every customer is considerably less than the demand possible with his installation; also that the maximum demands of all these customers are by no means simultaneous; the net result being that the maximum load, or maximum demand, on the works is from 45 to 65 per cent. of the maximum possible load—thus, the actual liability, in respect to provision of plant (and, in a lesser degree, of mains, etc.) and in respect to capacity of running plant, is very much less than the apparent liability. Again, with regard to the predicated class of customers, experience has demonstrated that the time-load curves of one year are very similar, except, perhaps, in the first two or three years, to those of another, and that a time-table of actual liability can be drawn up with a fair amount of accuracy; such a time-table will show, of course, a relatively small liability, except during a few hours daily, in which the liability will rapidly increase to a maximum (variable with time of year), and then more slowly diminish. Discontinuity of supply to private customers for lighting is usually possible without these suffering inconvenience in the hours of broad daylight, but is not possible during the hours of heavy load; hence work on mains is easily arranged for, but spare plant is necessary at the works, and, on account of the period during which the load on the works exceeds 90 per cent. of its maximum value lasting for some three hours in winter, the plant capacity cannot be taken at an overload rate.

Mr. H. FARADAY PROCTOR, of Bristol, opened the discussion, and disclaimed the credit given him by the author. He had wished to help, but business had prevented him from doing more than discuss the question with Mr. Kilgour. He thought the paper would do much to educate committees and chairmen on the reasons for different charges being necessary to various classes of consumers. The great difference even between the lighting of churches and the lighting of streets showed the need for such a variation in charges. He agreed with the author's method of ascertaining the running costs. The result obtained of about $\frac{1}{2}$d. per unit agreed well with that given in Councillor Sinclair's paper read on Tuesday. The method described of dealing with rates and taxes in dividing up the costs was reason-

Digitized by Google

able. A system of different charges which varied with the class of consumers was the best.

Mr. C. E. C. SHAWFIELD, of Wolverhampton, differed from the author in his classification of rates and taxes amongst the running charges. These had to be paid even if no profits were made. A flat rate was not fair to different classes of consumers, as, for instance, public-houses and offices. He thought that they should have power to make higher charges to consumers at a distance from the power-house. Rather too much was made of calculation of the works' costs of supply when fixing tariffs. They should rather take courage and fix their prices to compete with rival undertakings, and then so organise their works that the costs were reduced to the desired amount.

Alderman IRVINE, of Blackpool, said that the maximum demand system met the case, but that, owing to the difficulty of explaining this to consumers, he preferred the flat rate charge. Committees had to consider the electors when discussing this question.

Mr. R. B. LEITCH, of Farnworth, did not consider the maximum demand system satisfactory. A flat rate with discounts in proportion to the load factor would be more readily understood by consumers. This was what gas companies did.

Alderman ELVEY ROBB, of Tunbridge Wells, thought it a difficult matter to find a satisfactory alternative to the demand indicators. It was a mistake to ask consumers to use apparatus involving calculations to determine charges. He believed that a flat rate would meet ordinary cases, and that special terms should be given to exceptional consumers. He believed that under the Acts they had power to make such special agreements.

Mr. J. F. C SNELL, of Sunderland, agreed with the maximum demand principle, and it could be applied, generally, by flat rates to different classes of consumers. In fixing tariffs a tortuous method of calculation from present costs was apt to frighten committees. He thought it a good method to first ascertain the standing charges and works' costs as at present, then to calculate what these would be a few years hence, and fix the tariff between the two limits, taking reasonable care to be on the right side. He did not agree at all with the author in his statement that equity had nothing to do with the matter. He needed to take every effort to get an equitable system of charging different consumers.

Alderman PEARSON, of Bristol, advised all chairmen to take their engineers' opinions on tariff as they would do on methods of working. He had found flat rates with discounts up to 30 per cent. for light and 20 per cent. for power satisfactory. As regards special charges, the present town clerk of Bristol considered that they had powers under their provisional orders to give special rates to individual consumers. Both the distance of the consumer from the station and his hours of use should be considered when fixing special rates.

Alderman KEMP, of Aberdeen, said that all classes of consumers should get fair play, and that the demand indicator offered the fairest system of charging. As chairman of both the Gas and Electricity Committees of Aberdeen, he was only concerned in seeing that people got the best light by either system at the lowest cost. It was not feasible to vary the charge with the distance from the works.

Mr. KILGOUR reserved the most of his reply, but said that any system of varying charges with the position of the consumer would be unfair. The location of the works was determined for engineering reasons, and all within the area should be treated alike.

The Supply of Electricity in Industrial Areas from a Municipal Point of View.

BY COUNCILLOR WILLIAM HODGSON, DEPUTY CHAIRMAN OF SALFORD CORPORATION ELECTRICITY COMMITTEE.

In the compilation of any up-to-date issue of an encyclopædia, the article under the title "Electricity" will require a very lengthy, technical, and comprehensive description to convey fully the varied uses, recent developments, and capabilities of this subtle force. Those interested have only to compare the heading under "Electricity" in the "Encyclopædia Britannica" recently reprinted by the *Times*, to note the very great and rapid changes which have taken place since 1879, before which year the electrical industry was unknown. The unprecedented and striking progress made in 25 years in what may be called "commercial electricity" has been very marked and significant, a progress much more rapid and extensive than has been accomplished by any previous engineering or scientific change, not excepting even the great invention and introduction of the steam-engine of a century ago, which produced such a complete revolution in the commercial and manufacturing industries of this and other countries. To this very pronounced and momentous change and the far-reaching and important effect it has and will have upon municipal electrical undertakings may be attributed the appearance of this paper. If it is the means of creating increased interest by all concerned and of assisting them in dealing with the important issues involved, the author will be well repaid.

Electric tramways and railways are recent illustrations of the practical application of electricity, but their advent is only of minor importance compared with the "upheaving" throughout the world which the extensive varied commercial and industrial use of electric power is now forcing into prominence. Electricity is now generally acknowledged to be the most controllable and versatile form of energy yet discovered by man. The near future will *demand* a supply of cheap electric power to be available whenever and wherever it is wanted, and whilst making no attempt at prophesying, the author is strongly of the opinion that the direct use of steam power will wane and become in a few years probably as "ancient" as water mills are now. It is this new and unforeseen condition of things, coupled with the clearly demonstrated and increasing demand (and to which there seems no limit) of recent years for electricity for *all* purposes, which puts additional responsibility upon the committee entrusted with the carrying out of the electricity "order" of municipalities which have already undertaken the generation, supply, and distribution of electricity for light and power to private consumers and energy for their tramways, and they must, therefore, give it the careful thought and consideration it demands. Experience has already shown that even in so short a time most committees are finding themselves compelled by these changes which have been forced upon them to decide—if their undertaking is to be of a progressive nature and having regard to the size and capacity of plant already installed, which in consequence of steady and increasing demand is rapidly approaching its maximum output—whether a further extension on a comprehensive scale of such plant or works is desirable.

To arrive at a sound conclusion, the members of the committee are called upon to consider not only *their* direct responsibility to carry out the "order" for their corporation to supply electricity within the area named, and in accordance with the general conditions of such "order," but whether they, as representing for the time being the general body of ratepayers, who find the capital and whose pockets are affected, and who are seriously concerned in both present and future prospects—should encourage and promote a further and increased application and development of electricity for *all* industrial demands. They must also guard against what seems to be the tendency of the present time—viz., to unduly increase municipal liabilities—by taking care that any scheme or extension they recommend for adoption shall not only have full consideration, but that there must be some reasonable prospect of an adequate return from such outlay, and that it will not become an additional charge upon the already overburdened ratepayers. It is obvious that engineering, commercial, and financial policy enter into the question, and each in turn must have full consideration by committees when determining conclusively a sound future line of action upon which so much depends. Electricity works are not now placed under the category of "scientific experiments." They have entered into the running of commercial enterprises, and the first consideration now is whether they can be successful from what is called a "business" or "will-it-pay" standpoint, which, after all, is of paramount importance, and any new development or extension will have to answer *this* test. The engineering, scientific, and technical section of the undertaking must act in harmony and sympathy with, and to a large extent be controlled by, enforced commercial and financial considerations, these two latter being often by their supreme importance placed in front of engineering achievements.

It is universally admitted that the use of electricity for almost all purposes has made enormous advances in recent years, and there is no sign of the rate of progress slackening. In fact, this admission, so very apparent along with definite and conclusive figures which could be given if necessary, declares undoubtedly in favour of its still increasing extension. The electrical world seems to have entered upon a new and vigorous phase, opening up new possibilities and imposing new or altered conditions, and it is incumbent upon those responsible to realise and grasp intelligently the new state of things, and to lay themselves out for coping with this new but pronounced

Digitized by Google

demand, by either adding to their present stations or making provision for others on the most economic "up-to-date" lines. These conditions being acknowledged, the committee having charge of this important branch of municipal work cannot assume a passive indifference, and, Micawber-like, wait for "something turning up." They must perforce also take seriously into their notice the fact that recent events are revealing the tendency of bringing into being large power companies in different parts of the country with practically unlimited capital, whose schemes involve the putting down of immense plant with the object of supplying current for all purposes cheaply in manufacturing and residential districts. These power companies covering vast areas are now in evidence, and have in some cases commenced operations, and they are offering prices for a combined lighting and power supply such as the municipalities have not even thought of—for instance, in the neighbourhood of Manchester, contracts are being made by a power company at prices varying between ½d. and ¾d. per unit. There are also other projected companies now seeking parliamentary powers to supply in areas already covered by "orders" granted to municipal authorities.

With these facts before them, and having in view the prospect of competition, electricity committees would be unwise in adopting a "dog-in-the-manger" policy; they must now face the situation imposed upon them, and act in and for the interests of their constituents, and at the same time arrive at a clear and definite policy for future working. It must be borne in mind that, in order to obtain consumers, the power companies have frequently to transmit their power several miles, involving heavy capital outlay on cables, and an appreciable maintenance charge. If the power companies can afford to supply at the low figure mentioned in spite of the distance over which the power has to be transmitted, surely the municipalities, with the demand for energy at their very door, can do so even better. What, then, is the reason that municipalities have not yet been in a position to offer the low rates for power such as the power companies are now contracting for? The answer seems to be two-fold: (*a*) they have not realised the possibilities of power supply on a large scale, and are consequently not prepared for it; (*b*) they have hitherto hesitated to lay out the large sums of money required for adequately dealing with the problem.

With regard to the first reason, it is now evident that there is a demand for cheap electrical power, and that the demand can be met and consumers supplied at a reasonable profit from power stations designed on broad lines, but with strict regard to economy in both buildings and equipment, such a station would probably be designed for high-voltage plant on account of the heavy powers to be dealt with, but it would work economically in conjunction with a low-tension station, such as is usually found in most industrial areas. It would probably be possible to shut down the power station altogether during certain hours of the night, the supply being maintained from the low-tension station. In the next place, with regard to the financial problem involved in a general power supply, the Legislature has placed upon corporations certain clearly defined responsibilities—in fact, in their areas they have, generally speaking, been given "for better or for worse" a monopoly of the supply of electrical energy. It is, therefore, the duty of municipalities to see that the privileges and advantages which the power companies are offering the country districts are available also for town areas; in other words, the municipalities, having been given a monopoly within their area of the public supply of electricity, are bound to undertake the supply of power on a sufficiently liberal scale to ensure the town manufacturers, often large ratepayers and employers of labour, the same facilities as will shortly be available in the country, and should they fail in their duty in this respect, they must not be surprised if the Legislature curtails the present monopoly and grants to power companies the rights to supply power to users in municipal areas.

Large towns, probably towns of 100,000 inhabitants and upwards, can undoubtedly deal with the problem themselves in a highly economical manner, but it is quite possible that small towns may find it advisable to take power in bulk from a power company, but local conditions may largely enter into the question, and must be carefully considered in each case. It must not be overlooked, and may at once be conceded, that ratepayers requiring power have also rights and privileges which must be recognised and ought not to be set aside, and municipalities should learn that it is inexpedient to stand between such ratepayers and a cheap supply of electricity for power purposes, which would probably mean the increased development of the district. This fact ought to induce them to adopt a sound progressive policy, or give facilities to a power company to provide what they are either unwilling or unable to furnish—*i.e.*, electrical power at the lowest rates. Municipalities have many advantages over companies. They have compact areas, goodwill, financial strength, and the necessary parliamentary powers; all that is required is for them to meet the exigencies of the situation and cater for the demand which has undoubtedly arisen; failing the adoption of this course, it is their duty to assist and not prevent others who are prepared to do so from carrying out the work. With plant rapidly approaching its full capacity, electricity committees are now, therefore, faced with the question, and must answer it: Is new additional plant to be put down by them with a view to affording manufacturers a cheap supply of electrical power with a probable small margin of profit to the corporation? or is the alternative to be adopted—viz., to maintain the present comparatively high price of current, with its tendency to discourage large consumers, and so render further extensions unnecessary, or, in other words, contribute to their own extinction? The author has no doubt that the right decision of the committee would be to answer the question in the affirmative and determine upon a progressive policy.

The trend of financial, expert, and progressive opinion is to make or produce electricity so cheap that no one will be able to do without it. This may be a high and laudable ambition, but if that application can only be realised, we cannot tell what advantages it may bring to both industrial and residential areas. It is more than an aspiration, it is a probability, and its accomplishment would mean the providing of cheap power for trains as well as trams. It would operate docks and canals, it would dispense with the unsightly tall factory and works chimneys for ever belching forth dense black smoke, it would shut down the thousands of chimneys of dwelling-houses through which the air-polluting domestic fires emit their poisonous atmosphere, and which are so largely responsible for the fogs experienced in our large cities and towns; in their place we should have cheap light, power, and heat, besides other apparent advantages, the description of which is outside the scope of this paper.

In summarising the subject, the leading or principal factors which municipalities are bound to give their attention to seem to be: (1) the demand on all sides for *cheap* electricity; (2) the recognised and acknowledged use of electricity as an economic agent in the transmission of energy; (3) its coming universal application; (4) the claims of their own ratepayers; (5) the effect of the new and increased demand upon present generating stations; (6) the advent of large power companies and possible competition; (7) the course of action of those responsible under the new conditions.

Alderman PEARSON, of Bristol, opened the discussion, and said that the Corporation of his city recognised that the electrical future of the city was in their hands. They had no idea of allowing a power company to come in to compete with them. The means they took to prevent it was to so conduct their undertaking that they could not be competed with. They had no fear of incurring a proper outlay in extensions, and did not look upon this outlay as an additional indebtedness, but rather as a municipal investment. As long as they could raise money so much cheaper than a company, he felt sure that their district was safe. He thought, however, that if a municipal undertaking could not supply power at about 1d. per unit, they had failed to fulfil their duties, and must be prepared to accept competition. In their case, within six months of the power company's Bill being passed £125,000 was voted for new machinery to supply power consumers. It was true that they now had to pay about 3½ per cent. for their money, but companies could not get it for that. The recent return made to Lord Camperdown's Committee showed that out of 23 Power Bills which had been passed only six of the companies were in active operation. He thought that a great number of the proposed companies would never be heard of again. The reason was that it was cheaper to supply power to consumers who were reasonably near together than when they were scattered over a large area. This favoured the municipal undertaker. A cheap supply of power also tended to attract manufacturers to a town.

Alderman IVEY, of West Ham, said that there was no monopoly conferred on the holder of a municipal order. He quoted the case of Finchley to show that by means of overhead wires a supply could be given without statutory powers. He thought it was the fault of the municipal authorities that there was a risk of their losing the sole right to supply electrical energy in their districts, and also that certain municipal undertakings had not paid. Electricity stations had been put down in exceedingly bad positions, where the cost of coal transport was great and there was no water for condensing purposes. He thought that they should be more ready to push their undertakings, so as to be in a position to supply any consumer. The policy of waiting for an assured margin of profit before

Digitized by Google

making extensions was responsible for the present position. Alderman BUZZEY, of Poplar, also urged those present to increase their equipments so as to develop power load. In this way, by catering for all consumers, they should be able to keep out the power companies. He considered that the power company now under consideration before the House of Commons would prove, if passed, to be a monopoly which would afterwards have to be bought out at a very high price, as the water companies had been. He thought that even now the promoters would be prepared to sell their Bill.

Alderman BRUCE, of Sunderland, explained the position his undertaking occupied as to the supply of power in bulk. The area around was in the hands of a power company, but under the advice of their engineer, Mr. Snell, they had spent £75,000 on the extension of their plant. By means of this they were able to supply the shipyards and engineering works within their area, and to save them putting in their own generating plants. They had one contract for five years at the rate of 1⅛d. per unit. He questioned the lower prices which were given in the paper, and thought that they must be for the supply of high-tension current, which would have to be transformed. As a result of their power supply, they had been able to give a 10 per cent. reduction to their lighting consumers. Their power factor had gone up from 17 per cent. to 22 per cent., and they expected it would reach 26 per cent. when more power consumers were supplied.

Bailie MCPHERSON, of Edinburgh, did not think Alderman Ivey's suggestion of supply from overhead wires as at Finchley could be generally applied. It was the corporations lagging behind which led to the companies obtaining powers, and they must keep pace with the times to check the tendency in parliamentary circles, which at present was to encourage company trading.

Mr. H. FARADAY PROCTOR, of Bristol, said that his undertaking were now supplying one consumer at the rate of $\frac{13}{16}$d. per unit, and he thought that the contract was a profitable one. He deprecated any disinclination to trust engineers on financial matters, as to supply cheaply was the great aim of the engineer. He quoted the American saying that "an engineer was a man who could do for one dollar what any fool could do for two."

Mr. A. H. SHAW, of Ilford, said that the Tyneside Company were supplying motors and other accessories to their consumers as well as power. Unfortunately, many local authorities had not power to do this.

Mr. J. H. SNELL, of Sunderland, defended the price of 1⅛d. per unit, which one speaker had thought was too high. He had found that of two private installations in Sunderland the cost of production in one case was 1⅛d. per unit, and in the other 1·08d. He thought, therefore, that the Corporation were quite right in charging 1⅛d. per unit if consumers could be obtained on those terms. The Tyneside Company did supply motors, and the loan charges for them were heavy. He thought that frequently the electrical energy was sold at too low a rate, and the loss made up out of the high rates obtained for motors.

Councillor HODGSON, in a short reply, said that the holders of municipal orders practically have had a monopoly up to the present time. He thought that they should keep companies out by supplying cheaply. He could give no further details as to the supply for which ½d. to ¾d. per unit had been quoted. In his area they were just bringing into force a new tariff, under which motors could be supplied at 1⅛d. for the first 1,000 units for the first quarter, and 1d. per unit for all above this.

At the close of the meeting the members of the association were entertained at luncheon by the Corporation in the City Chambers. Lord Provost Sir John Ure Primrose presided, and there were about 350 seated at the tables.

The LORD PROVOST, proposing the toast of "The Incorporated Municipal Electrical Association," remarked that to-day no dwelling could be considered up-to-date, and even in the highest sense sanitary, unless electric lighting was the method of illumination, and a city could not be classed as in the first rank which had horse haulage on its tramway system. He ventured, however, to caution both officials and members of public corporations, in seeking to further these municipal undertakings, to bear in mind that they were founded and built up at great capital cost, in these progressive days, without any certain tenure of life, and that it was necessary, therefore, that sinking funds and reserve funds be built up, and profits not taken for the relief of the rates.

THURSDAY, JUNE 29.

Extensions to Outlying Areas.

BY A. B. MOUNTAIN, CHIEF ELECTRICAL ENGINEER, HUDDERSFIELD.

The Municipal Electrical Association, at its first annual convention, held in 1896, discussed an important paper read by Mr. A. H. Gibbings upon "Extensions to Outlying Districts," the consideration then being confined to the value of extending mains from the central portion of a town to its residential suburbs. The discussion upon this paper was most interesting, and will well repay members for reading again. To somewhat reduce the scope of this paper, it is proposed to confine the problem to extensions to the urban or rural districts, which in so many cases are found surrounding the incorporated areas, and into which the population of such towns has extended or is now spreading. In the author's opinion, the subject requires consideration from two distinct points of view: (1) the policy of extending the area of supply into districts governed by other authorities; (2) the engineering problems connected with such extensions.

Considering, first, the question of policy, it may be well to think of the probable development in matters of municipal government and the position of our electrical and other undertakings in the future. The work of the municipal authorities has during the last 30 years been enormously extended, not only in the direction of public improvements to streets, efficient drainage, public recreation grounds, and other work connected with and necessary for the better development of public health, but the control of such important undertakings as the supply of water, gas, electricity, and trams has involved the authorities in works in the nature of trading undertakings requiring special knowledge and most careful management. The control of education has still further increased their responsibilities. In the author's opinion, the duties of the authorities must be still further increased by the addition of many other matters, including the work now undertaken by the guardians of the poor, as it seems ridiculous to suppose that the authorities responsible for the good government of a city in all other matters should not be able to look after its poor, and the enlargement of the boundaries of the boroughs or cities to cover the areas now under the direction of the guardians must sooner or later follow.

The problem of housing the working classes is now receiving the earnest attention of the councils of many of our large cities, and electric traction has simplified the solution to a large extent, by enabling the working classes to live a considerable distance from their work. Obviously, the fact of spreading the population over a greater area must be of advantage from the sanitary or public health point of view, and the rents of houses constructed in the outer districts should be considerably lower, but the central authority, by adopting this course, would possibly reduce the rateable value of its own area, while increasing that of the outer districts, and deprive its trading department of revenue, unless these commodities were extended to such areas. The fact that large works are now being built in these outer districts, owing to the lower cost of land, and in many cases lower rates, is a serious matter for the central area financially, although no doubt very desirable, as it enables the workman to live in a healthy district yet close to his work. The extension of tramways has largely assisted this movement, and if cheap electricity can be provided for motive power and lighting a still further drifting of the population should ensue. Many corporations are supplying water and gas, and a few are supplying electricity to the adjacent areas, and in practically every case are charging from 10 to 25 per cent. more outside the boundary of their own area.

It is difficult, at the present time, to understand how and why the existing boundaries were formed, and it would certainly seem extremely desirable to have a readjustment. We find in some cases two towns actually side by side, managed separately with duplicate undertakings, which could by combination even now effect very considerable economies; or, in other cases, we find the central or principal area surrounded by districts in which the actual workers of the town reside, whose interests are identical with both areas, and yet, in many cases, the question of amalgamation has not been seriously considered. By deferring amalgamation enormous sums of money have been practically wasted upon the duplication of sewerage, water, gas, tramways, electrical, and many other works or departments, which could be more economically and successfully managed by one central authority controlling a large area. The argument of the outer

Digitized by Google

areas is nearly always based upon the fact that rates are lower in their area than in the central one, but this is only because their responsibilities are less, and the advantage in the rates is often more than counterbalanced by the increased charge for water, gas, and electricity. It is exceedingly difficult to define the limit of expansion for the boundaries of a town; it must depend, to some extent, upon the density of its population and the geographical surroundings; but assuming the question of housing the working classes to be a controlling point, the limit of residence from the centre of the town would be the time which it would be reasonable to allow for travelling night and morning, and assuming this to be half an hour, it would mean, taking 10 miles per hour as the speed of travelling, that the limit of residence would be within a radius of about five miles, and this would represent an area of 50,265 acres.

It was not suggested that it is advisable for one town to attempt to undertake the supply of other distant towns or villages, even although this is quite possible, and might, in some cases, prove financially successful; but it would seem to the author to be the actual duty of all the large central authorities to extend the electric supply mains into those districts immediately surrounding the central area, if it is considered probable that future extensions of their boundaries will bring these districts under the control of the central authority. If this will not be the case, the matter becomes a question of municipal trading, and it must be considered upon purely business lines. In many cases it will, no doubt, be profitable, but the revenue obtainable from the outer districts is usually small in proportion to the capital expended, and although the price may be increased to the statutory limit, this will tend to reduce the demand, and be of little advantage. The price to be charged for the energy supplied to the districts outside the control of the central authority involves several complicated points: the districts bear no risk of contributing to any losses upon the undertaking, nor do they receive any profit, but they contribute towards the repayment of capital or purchase of the works, which eventually belong to the central authority, so that the charge might be uniform throughout the whole area, if it were not for the fact that the cost of supplying such outer districts, owing to the increased capital outlay per consumer, is more than for the central position of the area. In most cases an additional charge of 10 per cent. would be ample protection, and, as will be shown later on, the cost of supplying electricity in the case of a small village installation is so low that it is doubtful if more than this could be obtained. If it be considered desirable to supply the outlying areas, a commencement should be made as soon as possible, because the neighbouring power company will certainly endeavour to supply these areas, and should they succeed and the area afterwards become amalgamated, it will no doubt be a costly operation to buy out the company.

Engineering Consideration.

Assuming that there are outlying districts within five miles of the centre of the town, and that such districts have a scattered residential population, with the houses on the sides of the main roads or in the form of small villages, it is obvious that the cost of mains per consumer will be very much heavier than in the central portion of the area, and it is also a fact that the revenue or units sold per lamp is less; consequently, it would not be profitable to undertake the supply upon the same lines adopted in the town unless such supply was a high-pressure one. But as most towns, owing to the development of traction and motive power, are now generating high-pressure alternating currents, the cost of mains may be, by the use of such high pressure, considerably reduced, and it is comparatively easy and economical to deal with extensions within the limits suggested. It is, of course, quite impossible to apply general rules to individual cases; the conditions will probably not be identical in any two areas, but if the outer districts to be supplied are of a residential character, the most suitable and economical arrangement would be to carry the high-pressure alternating current either one, two, or three phase by underground mains to the approximate centre of each village, reducing the pressure by static transformers and distributing by overhead wires.

The methods adopted for transformation and distribution will, to a considerable extent, depend upon the magnitude of the demand; if large, rotary converters can be employed with direct-current distribution, but in most cases it will be found more economical to employ static transformers, and the fact that the latter require practically no attention will help considerably to reduce the cost of supply. One of the advantages of alternating current for distribution is that the drop of pressure does not matter for isolated consumers. It will, no doubt, often happen that an extension of perhaps half a mile is desired to reach some important detached residence; this would probably mean a drop of 20 volts or more upon the main, with which variation it would be impossible to supply satisfactorily, but by fixing a regulating transformer at the consumer's house the pressure may be kept constant and a considerable saving in capital effected. The cost of connecting consumers who will only contribute a small amount of revenue is, however, considerable if the distribution is by means of underground mains and service. The author has found from actual experience that the average cost of connecting consumers by underground low-pressure service is about £7. By adopting overhead wiring for distribution, the average cost of the service is reduced to about £4, in both cases meters and fuses being included.

The cost of overhead mains in a system where conductors of small sectional area are to be used may be put at about half the cost of underground mains, the heavier the main the less being the advantage of placing the same overhead. There are other advantages with an overhead distributing system which make it particularly suitable for outlying areas. Extension may readily be undertaken to detached houses, at little cost, and with practically no risk of capital, because the poles and wires may be taken down if desired, and used elsewhere. The area of the main can at any time be increased by simply putting up a larger wire in place of the smaller, which is then available for use in other places, so that very considerable extensions may be undertaken with a very small expenditure of capital at the commencement. The connection of consumer's premises does not necessitate the cost and annoyance of disturbing the surface of the roadway or footpath. The cost of maintenance compares favourably with underground mains, and repairs are of the most simple kind and do not involve skilled supervision. At present, however, the feeling against overhead mains seems so strong that it is only possible to obtain consent for their erection in the more enlightened areas.

In some cases the district council may prefer to purchase in bulk and distribute themselves. From the consumer's point of view there is little to be said in favour of this arrangement; it must increase the charge, due to the extra engineering and clerical supervision; it will cost the central authority very little more to keep in order 50 extra meters, take readings from the same, and render and collect the accounts, whereas the district council would require to engage someone to do this work and generally supervise the distributing system, which would cost from 10s. to £1 per consumer. This useless addition to the cost will make it very difficult in small places to obtain consumers. The pressure at which the supply is to be given should have careful consideration; it is essential that the small houses and cottages should adopt electricity, and in such cases the cost of lighting is the important factor, which is materially affected by the efficiency of the lamps, and, since a lamp of 5 c.p. and 8 c.p. will predominate, the lower the voltage can be kept the better. But the low cost of supply, although most important, will not be sufficient to induce the small consumers to adopt electricity. Prepayment meters, with or without free wiring, are essential, as the working classes, as a rule, are unable or unwilling to pay bills rendered quarterly or half-yearly.

There are several advantages in supplying the surrounding areas. The load factor is improved, due to the following facts: The market day in the town is usually the village half-holiday. Fogs, thunderstorms, and dark clouds seldom cover the whole area at the same time. The demand being mainly for residence lighting, the load upon the works will be prolonged until late in the evening. The street-lighting which may be obtained is of considerable assistance to the revenue and the load factor, and if overhead wiring is adopted the lamps may be fixed most economically upon the poles and a switch wire run back to a central position, so that all street lamps may be switched on or off from one point without the expense of lamplighters. The enlargement of the demand reduces the proportion of the standing charges per unit sold throughout the whole area.

To give some idea of the comparative cost of supplying from a small village installation and by means of mains extended from a central area, and to emphasise the importance of keeping down the capital expenditure, particulars are given of an existing installation just completed by the author, and the estimated cost of supplying from a central source by underground and overhead distributors. The population within the area is approximately 4,000, the estimated number of lamps which will be connected at the end of the second year, 2,800 of 8 c.p. The revenue, based upon the present consumption, will be as follows:

16,760 units sold to private consumers at 4½d. per unit ...	£330	1	8
3,240 units per 40 street lamps ...	40	0	0
Meter rents ...	20	0	0
	£390	1	8

Capital Expenditure, District Council's Installation.

Cost of generating works having a capacity of 68 kw.—gas-engines, dynamos, and switchboard ...	£1,400	0	0
Overhead wiring 6½ miles, services and meters for 80 consumers, 40 street lamps ...	1,600	0	0
	£3,000	0	

Central Supply with Overhead Distributors.

Proportion of cost of generating works, 68 kw. at £20 ...	£1,360	0	0

Supply from Central Area with Underground Distributors.

Total cost for 20,000 units sold in the outer area, excluding capital charges	1·00
Interest and sinking fund charges, 6 per cent. upon £5,350	3 85
=£404. 3s. 4d.	4·85

From the above statements it will be seen that by adopting overhead wiring a difference of ¾d. per unit could be made in the charge, which, as already pointed out, is of the greatest importance when dealing with small consumers. The comparisons are, of course, only true during the first few years. As the feeders become loaded the capital charges per unit are reduced; the proportion of the capital allowed for the generating works is also reduced, due to the improvement in the load factor. In conclusion, the author trusts that this paper and the discussion which may follow will be the means of stimulating local authorities to develop their electrical undertakings and carry light into many of the dark surrounding areas.

Mr. S. L. PEARCE, of Manchester, said that the subject of the paper was a most important one, but that the extensions to supply outlying areas were often inadvisable from an engineering point of view. In Manchester they had found that the high cost of supplying certain areas taken into the boundaries, had prevented them from using the powers which they had to do so. He thought it inadvisable to charge a higher rate to these outlying areas. He had not found that any improvement of load factor resulted from the supply to the districts which had been connected up. A high-tension transmission must, of course, be used for such work, and he asked for further information as to the successful employment of three-phase distribution. He advocated that the number of sub stations employed should be kept down, so that large and economical units could be employed in the same. He had not found the Board of Trade unreasonable in giving their consent to overhead feeders, but the consent of small local authorities was exceedingly difficult to obtain, even for the supply of tramways in rural districts. He warned those present against being led away by outside considerations to increase their unremunerative expenses on mains.

Mr. R. A. CHATTOCK, of Birmingham, considered that the supply of outside areas by a corporation was a considerable assistance to the absorption of those areas at a later date. He saw no reason for a five-mile limit, and proposed rather to supply all districts which housed the working classes of the central area. Up to the present Parliament were not inclined to assist the efforts of the corporations in this direction, and Birmingham had power to supply in bulk in certain areas, but not to distribute. He thought this was a mistake, as it involved a double profit. The Board of Trade were not unreasonable as regards overhead wires. He advocated supply being given for a radius of 1½ to 2 miles from the sub-stations. The proposed 10 per cent. extra charge was not feasible, in his opinion, and it was against the clause in the provisional order as to uniform rates of charging.

Councillor MCGAUL, of Birkenhead, did not see why ratepayers in the central area should supply outside the area at a loss. In Birkenhead they charged such areas at 1d. extra per unit, and the Board of Trade had not objected.

Mr. J. G. GRIFFIN, of Swindon, described how boosters should be used to supply outlying areas. With these connected between the main 'bus bars and the spare 'bus bars to which the long feeders were connected, considerable saving in copper could be effected. The system could be used up to a distance of three miles.

Mr. J. K. BRYDGES, of Eastbourne, believed in charging higher rates to outlying districts, and had arranged to do so in one case, before the application was considered by the Board of Trade. His committee in this case had secured a three years' guarantee from large householders in the district, which ensured the Corporation against loss. He employed boosting transformers in the feeders and charged ½d. per unit more.

Alderman HEY, of Halifax, said that the local ambition of small authorities frequently led them to lay down plant where it was quite impossible to make it pay. Two small areas outside Halifax had done this, and were now keen to supply current to his Corporation. In one case a refuse destructor had been put down, from which the authority wished to supply the trams. Hardly enough refuse, however, could be obtained to light a few arc lamps in the streets.

Mr. A. E. HADLEY, of the Electrical Company, Limited, lamented the fact that we were behind other countries in the supply of small communities, because overhead wires were not used. He knew of one district on the borders of Russia where 20 small villages, with from 200 to 300 inhabitants each, were supplied on the high-voltage three-phase system by overhead wires. Three-phase distribution was used, and the undertaking showed 7½ per cent. profit. In this country 40 miles of 20,000-volt overhead line had now been arranged in the county of Durham. This would enable collieries to be supplied which could not otherwise be reached. He thought it would do good if the municipalities made it clear to Parliament that progress was seriously impeded by difficulties in obtaining rights to put lines overhead.

Alderman PEARSON, of Bristol, gave particulars to show that Parliament did not favour a local authority going outside their area. In Bristol they wished to supply a detached portion of the borough at Avonmouth some six miles away, and had been refused by Parliament wayleaves through adjoining districts. The power companies which now surround most of our large towns were, of course, the strongest objectors to such wayleaves, and to the extension of municipal supply to outlying areas. He gave some amusing incidents of the extreme difficulty of extending municipal boundaries which could only be done by a long parliamentary fight.

Councillor CHATTERTON, of Huddersfield, held that personal questions rather than business or engineering reasons decided the matter before them. The members of small local authorities had a very high opinion of their own importance, and opposed anything which tended to detract from the same. After chaffing Mr. Mountain because he had supervised the laying down of one independent plant in an area outside Huddersfield, he advocated a cheap supply to keep power companies out of their areas. They must also see that their capital account was not inflated by items which ought to be met out of revenue.

In reply, Mr. MOUNTAIN said that the districts round Huddersfield were smaller than those round Manchester and more dependent on the central area. He thought that this accounted for the fact that his load factor had been improved. They had an increased output from the supply of these outside districts, but the maximum load was not increased. He used three-phase current for transmission, but distributed as three single-phase currents. He had actually carried out overhead wiring with the approval both of the Board of Trade and the council of the outside district. He was pleased to find that, as a rule, the chairmen who had spoken agreed with an extra charge being made, as it was not right that the supply should be given at the cost of the ratepayers. This extra charge would afterwards be an argument in favour of incorporating the area in question.

Electricity Supply by Free Wiring and Prepayment Meters.

BY ALFRED R. SILLAR, CHIEF ELECTRICAL ENGINEER, COLCHESTER.

The object in bringing this paper before the association is to give a few hints to those station engineers who have never seriously considered the introduction of free wiring and the supply of current by means of prepayment meters into their towns. The reason that prompted the author to write this paper was the receipt of a circular letter which was kindly supplied to each chief electrical engineer by Mr. J. B. Mitchell, of Woolwich, this being a summary of replies received by him with regard to free wiring. In this summary the author was very much surprised to see that several electrical engineers of large towns had definitely stated that they did not encourage this system of supply, as it caused a considerable amount of trouble, and there was nothing to be made out of it. His reply to the gentlemen who made these statements is this: "Your undertaking has to compete with the local gas company or department in the supply of lighting and power, and if you cannot compete with them in the smaller branches of the business the competition is not real, and your undertaking must be the loser by it."

The supply of electricity by free wiring and slot meters is one which affects the residences of the lower, middle, and working classes almost entirely, together with a large number of small shops, the tenants of which live from hand to mouth, and cannot afford to spend money on an installation. These small consumers can be brought to be a very useful source of supply, and at the same time they will be found to be a first-class method of advertising the light, and the author is prepared to prove that since the introduction of free wiring he has received a number of applications for current on the ordinary system, which he would not have had had it not been that the consumer was recommended by a working-man who had already got a supply in his cottage. If distributing mains have to be laid in streets before a supply can be given on these lines, great care should be exercised as to the value of the class of property therein before determining a move. The author finds that a road filled with houses built some 30 or 40 years ago, and tenanted at about 5s. 6d. a week clear, will not give a single application when canvassed, whereas a road with fairly new property of from five to ten years' standing, renting at about 7s. a week clear, will bring an application from nearly every other house. The usual type of house which makes the best consumer is the one with about six rooms, with or without an entrance hall. The man who wants electricity in his house is the better-class artisan and shop assistant who is accustomed to have it at his work and knows the benefit of it, and at the same time the author finds that a large number of labourers, warehousemen, etc., earning not more than £1 a week avail themselves of a supply.

With regard to canvassing, the author's method of procedure has always been as follows: While the cable is being laid in the road two circular letters are forwarded to each house. The first one explains that a supply will be available immediately, and sets forth at length the advantages of electric lighting over other methods of illumination. The second circular is given verbatim, as it may be useful to engineers who have not yet adopted this system: "I am directed by the Electric Light and Power Committee to inform you that they have established a system of electricity supply in the borough by means of free installation in conjunction with penny or shilling in the slot meters at the option of the consumer. In the case of business premises the Corporation will supply any number of 16-c.p. or 8-c.p. lights fitted to pendants or brackets, together with the necessary wiring, switches, etc., providing that the consumer can show that these lights will be in use a reasonable number of hours during the year. In the case of residential premises four lights would be installed as above in the following positions:

Hall	one 8-c.p.	pendant	or bracket,	one switch.
Front room	one 16-c.p.	,,	,,	,,
Back room	one 16-c.p.	,,	,,	,,
Kitchen	one 8 c.p.	,,	,,	,,

Any reasonable alteration to the positions of the above lights will be considered by the borough electrical engineer, and any further lights will be supplied and fixed by the Corporation upon the payment of 8s. each. The cost of current supplied to the consumer under this system would be as follows: for a 16-c.p. lamp, about three hours 1d.; for an 8-c.p. lamp, about 5½ hours 1d. In order to keep consumers' lamps in as good a condition as possible, a new lamp will be given upon application at these offices after the consumption of each 40 units registered on the meter. In all cases premises will be connected to the Corporation's mains free of charge. My representative will call upon you in a few days' time and will give you any further information you may require." These two circulars are enclosed in an envelope and addressed "Important" with slip stating that a representative will call upon a certain day, and they are followed up with an evening visit by one of the members of the staff, usually the chief clerk, who is in a position to explain any details which the would-be consumer might not understand. The representative also takes with him some copies of the agreement, and anyone deciding to take a supply fills up this form and has it witnessed. This agreement has been purposely kept as simple as possible, so as not to frighten intending consumers, and is made between the town clerk as acting for the Corporation, the consumer, and the landlord. The use of the agreement is to keep the installation in the hands of the Council, to insure access to the installation at all reasonable times, and to prevent the consumer or landlord from interfering with it. The consumer or the landlord may purchase the installation any time on payment of the full value, and the Corporation reserves to itself the right of removing it at any time when it might be considered necessary. The author has, up to the present, no scheme whereby the consumer can be compelled to use the current for a given time and not return to gas, as he is given to understand that the legal difficulties in connection with a clause like this would be very great. A word of advice with regard to canvassing may now be given. The best man for the work is one who is thoroughly acquainted with the townspeople, and when the population does not exceed 100,000 some member of the office staff is sure to be found with this qualification. At the commencement the author employed a regular canvasser, but he quickly found that this was wrong, and at present all the canvassing is done in the evening by a clerk, as this has been found to be the best time of day to interview the class of consumer in question.

The author now passes on to the installation and the method of fitting up premises. The Corporation do not undertake any work in connection with free wiring, but a specification is issued for 50 installations at a time and given out to a local contractor. In the cottage or dwelling four lights are supplied, the one in the hall being merely an encouragement for obtaining consumers, as the revenue from it is practically nil, and the other three—those in the front room, back room, and kitchen—always pay their way. Consumers are also given the option of having the hall light fixed in a bedroom as a further inducement, the gas company only allowing three lights and making an extra charge for anything further. The present cost of these installations, taking 50 at a time, is 35s. per house exclusive of the lamps, which are supplied direct from the department, and the total cost of a house wired as far as the meter is, therefore, about 39s. In laying the service main where the applications are sufficiently numerous, the cable is looped from one cottage into the next, in some cases three or four being connected in this manner. The average length of twin $^{3}/_{20}$ vulcanised cable per house is 12 yards, and this, with the cost of the joint-box, house terminal box, meter board, meter, and the men's time laying and fixing, averages over the whole of the installations £4. 19s. 3d. The greatest item of cost attached to free wiring is that of the prepayment meter, and although there are a number of meters on the market at a fairly cheap price, the author has found by experience that it pays in the long run to get a meter which will be as nearly reliable as possible, even if the cost of it is considerably higher than the average. At the present time he is using three different types of meters, two of the mercury motor and one of the shunt motor type. Of these meters he considers that the mercury is the better, as the great trouble of the motor stopping through a dirty commutator is avoided.

A large number of defects are continually showing themselves in the present designs of slot meters, and the author believes it will be some years before the manufacturers will properly perfect them. In one type of meter in use at Colchester, discs are used to actuate the working in order to avoid stoppages through inequalities of the coins. The discs, however, are not a success, as they frequently get hung up in the mechanism of the meter and stop it while keeping the current on. With regard to the meters which are directly actuated by the coins, those with a long distance to travel should be avoided, as the shorter the way that a coin has to go the less chance it has of sticking. Some meter makers like to guard their penny meters against the possibility of a halfpenny working them, and also to try to prevent a disc or token being used of slightly larger or smaller diameter than a penny, but the result of this is, that when a bent or oval coin is used the meter hangs up, and the consumer gets his light for nothing. In a prepayment meter the motor and dial must be kept absolutely separate from the receptacle for the coins, and most meters have two different sealing doors fitted. The author has tried a good many different types of lamps on the slot system, and, amongst others, some very high efficiency ones, which gave nearly 25 per cent. more light for the money, but owing to the complaints of blackening he has gone back to a first-class four-watt lamp, and finds that it cannot be improved upon this type of supply. With regard to the most popular type of meter. In the initial stages of free wiring, on the canvass form the question was asked as to whether penny, sixpenny, or shilling meters were desired,

Digitized by Google

and practically the whole of the replies were in favour of the shilling meter. Since, however, the system has been started the author has found that a certain number of applications from the poorer parts of the town have been received for penny meters. At the present time there is one penny meter in the town to every three shilling meters, and he has never yet had an application for a sixpenny slot meter.

The price for current charged up to the present has been 6d. per Board of Trade unit, as compared with 5d. less 5 per cent. for cash received from ordinary consumers, and the difference allows a sum of 1d. per unit for the repayment of the installations. Since April 1, however, the price to ordinary consumers has been reduced to 4½d., and the slot meters are being changed by means of replacing the change wheel to supply current at 5½d. per unit. As the slot consumer pays cash for his supply, the author always considered him entitled to the 5 per cent. benefit given to the ordinary consumers, and he has lately introduced a plan whereby any slot consumer having used over 40 Board of Trade units can obtain a new lamp by calling at the offices, where the claim is verified by reference to the meter register. The supply of these lamps serves a double purpose, as not only does it assist the consumer to replace his lights without any cost to himself, but it also keeps up the consumption of electricity and the revenue from these installations.

The author will now deal with the method of reading and collecting. At the end of every three months during the summer half-year, and every month during the winter, all prepayment meters are visited by an assistant from the meter department, and also a clerk from the borough accountant's office. The assistant reads the meter and registers it on a card, checking the money taken from the meter by the clerk. The clerk deals with the cash, and makes a similar check of the reading, and should there be any coins over and above the amount of the reading, which would represent current paid for but not consumed, these are returned to the meter. The working parts and dial of the meter are kept sealed by the meter department, and the cash part is locked with a Tourtell patent lock, the seals of which are kept by the accountant's department.

We now come to the principal question to be dealt with in this paper—that is, as to whether an installation on the slot system is a paying concern or not. First of all, to do this, some figures are given in relation to these installations which have been taken from the books of the department. The number of consumers dealt with are those which have been running throughout a complete financial year.

TABLE A.

Number of consumers, 82.
Units supplied, 7·433.
Units sold per consumer per annum, 90·6.
Amount received per consumer per annum, £2. 5s. 4d.
Average cost of installation complete with lamps, £2. 8s. 1d.
Average cost of meter, terminal box, and service cable fixed, £4. 19s. 3d.
Average cost of meter, etc., per equivalent 8-c.p. lamp, 12s. 3d.
Average cost of meter, terminal box, service cable, etc., to the ordinary consumer per equivalent 8-c.p. lamp, 1s. 11d.
Number of lamps actually connected, 422.
Number of equivalent 8-c.p. lamps, 655.
Number of lamps connected per consumer, 5·14.
Number of equivalent 8-c.p. lamps connected per consumer, 8·11.

In the second table the author proposes to show the financial result per installation, and to do this he must first give the cost of production, etc., at Colchester. The total cost for generation and distribution during last year was 1·70d., and the cost of interest and redemption divided by the number of units generated was exactly 1d. In addition to these, it will be seen in the figures given above that the cost of meters, service mains, etc., for slot consumers is more than six times as great as the average cost of meters and service mains of ordinary consumers, being in the case of slot meters 12s. 3d. per equivalent 8-c.p. lamp connected as against 1s. 11d. to ordinary consumers. As the cost of the installation is to be written off in five yearly instalments of 20 per cent. each, this amount will, of course, very largely reduce the profits on this system of supply, although it must be borne in mind that when the cost of the installation is paid off an additional profit of about 10s. per consumer will be realised. The author understands that some towns have obtained a special grant from the Local Government Board allowing them to borrow money for the installation costs of free wiring, but he has managed to pay for his system by means of an overdraft at the bank.

TABLE B.

	£	s.	d.
Revenue.			
90·6 units at 6d. per unit	£2	5	4
Expenditure.			
Cost of generation and distribution, 90·6 units at 1·7d.	0	12	10
Standing charges on 90·6 units at 1d. per unit	0	7	6
Repayment of installation at the rate of 20 per cent. on £2. 8s. 1d.	0	9	7
Additional interest and sinking fund on slot meters and service mains at 6½ per cent. on £4. 4s. 6d.	0	5	6
Cost of lamp renewals at 4 per cent. of the revenue	0	1	9
Net profit per installation	0	8	2
Total	£2	5	4

After five years have elapsed, and the cost of the installation is paid off, the net profit, taking the above figures standing as they are at present, will rise to 17s. 9d. per installation.

In conclusion, the author would remark that with all their troubles, which are sure to include faulty meters, extra cost for inspection and collection, and the inevitable consumer who never will get his correct amount of light for his money, he can only repeat what was stated at the commencement of this paper—viz., that this type of consumer is well worth catering for, if only for the competition which it brings to the gas company or department, and the advertisement which is the undoubted result.

Mr. R. B. LEACH, of Farnworth, opened the discussion on the above paper, and disagreed with a number of the figures published. The average income of £2. 5s. 4d. per installation was in his opinion too high, as the kitchen light was the only one used regularly. He also queried the cost of installation, which averaged only 9s. 9d. per light wired. He had found the slot meters unreliable. He did not think that with electricity at 5½d. they could meet gas competition in many places unless much more economical lamps were obtainable.

Mr. A. H. SHAW, of Ilford, had had considerable experience with the supply of small consumers in the way described by the author. With 123 houses, each with six lights, the average revenue was £1. 5s. 10d., which was below the author's figure. In Ilford they had supplied no shops on this system, which might account for the difference. The cost of installation averaged £3. 13s. 6d. His cost of connecting each consumer to the mains worked out at £5. 2s. 10d. They had now discontinued the system, but had induced builders to wire new houses, which brought them in touch with small consumers. They then gave one service connection to a whole block of houses. They still used some 400 prepayment meters, and obtained about £1. 10s. per annum from the same. The consumers using these meters obtained their lamps free.

Mr. E. T. WILLIAMS, of Gibraltar, said that half the revenue on the Gibraltar system was obtained from installations the wiring of which was rented. He did not advocate an additional charge per unit, but made a rental charge per lamp of 1½d. per month. This involved the repayment of the wiring cost over a period of 14 years. In order to save the cost of meters he had recently introduced a flat rate of 1s. 6d. per 8-c.p. per month, which he thought would give satisfaction. It was limited to installations with 10 8-c.p. lamps or under. In Spain this form of charging was largely used, and most of the wiring was done by flexible cords supported on insulators.

Mr. J. G. GRIFFIN, of Swindon, described the controversy which had raged in his town over free wiring. The outcome had been a standard specification to which any contractor could work, and the consumer paid the cost of installation on the three-year hire-purchase system.

Mr. H. R. BURNETT, of Barrow, had from 900 to 1,000 workmen's dwellings wired on the prepayment system, and obtained an average consumption of 100 units per annum from each. He had avoided the difficulty of free wiring by having an agreement with the builders. Also the landlords supplied and maintained the meters, which relieved him of the cost of upkeep. He had recently tried a new type of meter which would indicate the amount due. This would be collected each week, and the hand put back to zero. He thought that flexible cord of good quality run on insulators would be quite satisfactory.

Mr. C. TURNBULL, of Tynemouth, pointed out that the actual revenue the author obtained for his current supplied through the meters was only 3·8d. per unit, but that this was giving undue preference to the small consumer, which might lead to trouble from larger consumers. The $^{3}/_{20}$ cables for service connections was too weak mechanically, and he thought that manufacturers might use other materials for such small conductors to get mechanical strength. It was a good idea to have their clerks interested in canvassing.

Mr. W. A. VIGNOLES, of Grimsby, also criticised the author's figures, which he thought were dependent for their success on the high price of gas in Colchester.

Digitized by Google

Mr. H. L. P. BOOT, of Tunbridge Wells, had not yet obtained a good prepayment meter; most of those he had tried had not passed out of his test-room. He thought that 12s. per light was the lowest cost at which good wiring could be done. He estimated the repairs and depreciation would range from 12½ to 25 per cent. He advocated the discarding of meters to small consumers and making a flat-rate charge.

Mr. J. K. BRYDGES, of Eastbourne, gathered from information which had been supplied to him by Mr. Mitchell, of Woolwich, that there was not much to be gained either from slot meters or free wiring. In certain cases slot meters were so constructed that the coins could be pulled back if a thread was attached to them.

Mr. A. B CRAMB, of Croydon, said that where he had found trouble from slot meters he traced a good deal of it to the fact that inferior lamps were used, so that the meter did not run the length of time expected. Several of the lamps tested took from six to seven watts per candle. He now supplied a new lamp for every 35 units consumed, and complaints had ceased.

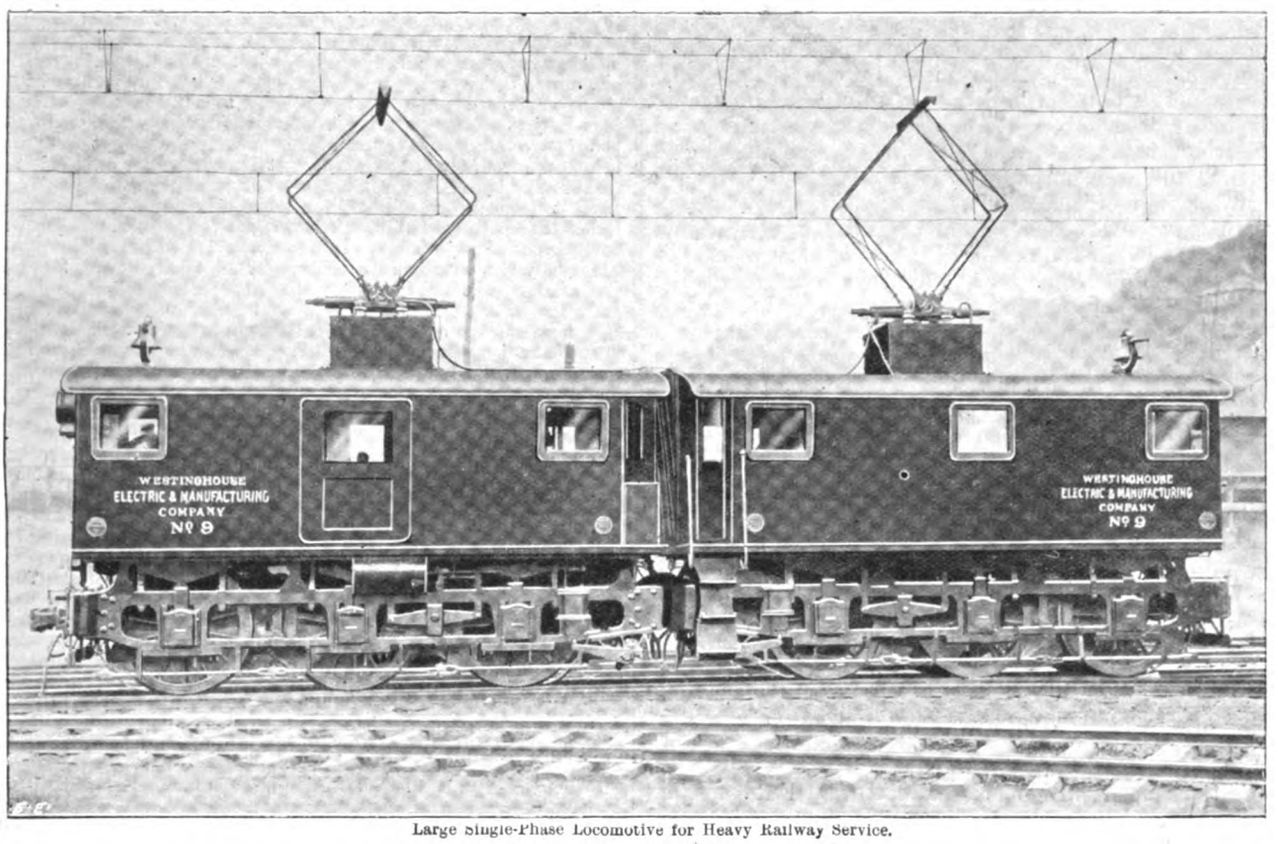
Mr. A. R. SILLAR said that he used a free wiring system with prepayment meters for small shops, and this doubtless accounted for the average revenue obtained. The wiring was done in casing, and the cost was low because of the keen competition amongst the contractors in his district. He was using the B.T.H. meter with success. The small cable used for service was lead covered and armoured, and there had been no faults due to mechanical weakness.

LARGE SINGLE-PHASE LOCOMOTIVE FOR HEAVY RAILWAY SERVICE.

Of the many interesting exhibits of railway appliances prepared for the inspection of the delegates to the International Railway Congress, probably the most novel, and certainly the most important in its bearing on the use of electricity as a motive power for heavy railroad service, was the Westinghouse-Baldwin single-phase alternating-current locomotive shown in operation on the Interworks Railway at East Pittsburg on May 16. This locomotive, built by the Westinghouse Electric and Manufacturing Company in order to convince the railway managers of the world of the possibilities and advantages of the use of single-phase current for heavy electric traction, was shown in operation first running light and then hauling a train of 50 new steel gondola cars weighing approximately 1,200 tons.

From the various details which are given herewith it will be seen that a number of new features are embodied in the construction of this locomotive, and that claims of priority may be made for it in a number of respects. It is, for instance, the largest alternating-current locomotive in the world, the largest to be operated by single-phase current, and it is equipped with six of the largest single-phase motors ever built. It is the first alternating-current locomotive for use in America, and is designed for the highest trolley voltage ever used in that country. This locomotive is also the largest ever operated by means of overhead trolleys, is the first on which forced ventilation is used in the motors, and is unique in many other similar ways.

The weight of the locomotive complete is 135 tons. It is built in two halves, each having one six-wheel truck with rigid wheel-base. These are coupled together, and are intended to operate normally as a single unit, but each half may be operated separately if desired. The locomotive is approximately 45ft. long over all, and 9ft. 8in. wide. The



Large Single-Phase Locomotive for Heavy Railway Service.

total height above the rail with trolleys lowered is 17ft. The wheels are 60in. in diameter, and are mounted on 8in. axles, with 6ft. 4in. between centres. The side frames of the truck are of cast steel, and are spring supported in the usual manner, the weight on the two inside axles of each truck being equalised. The cabs are built of sheet steel with angle-iron supports, and the entire cab as a whole is removable from the truck. Each axle carries a 225-h.p. single-phase series motor of the single-reduction type, making a total of six motors for the locomotive. One side of each motor is supported directly on the axle, and the other is suspended by spiral springs from the locomotive body. The motors are of the same general construction as the standard Westinghouse alternating-current railway motors of smaller size. They are so arranged that forced ventilation may be used, and increased output thus secured.

The locomotive is designed for a current of 25 cycles and a trolley voltage of 6,600, and one of the most striking points of the exhibition to those who have been accustomed to the enormous currents required in heavy direct-current traction work was the sight of so large a locomotive accelerating a 1,200-ton train over a third of a mile in length and receiving its entire power supply from

Digitized by Google

a single No. 000 trolley wire. The 6,600-volt current is collected from the trolley wire by a pneumatically-operated pantagraph trolley on each half of the locomotive, and is carried through a suitable oil switch and circuit breaker to an auto-transformer in each cab. These transformers reduce the voltage to 325 for use at the motors. The trolleys may be raised or lowered from the cab by a suitable air-valve.

The three motors on each half of the locomotive are connected permanently in parallel, and are controlled by means of an induction regulator, which, under the direction of the operator, varies the voltage at the motors from about 140 to 325. The induction regulators are driven by small series motors of the same general type as the main motors. Both regulators are controlled by the multiple-unit system from a master switch at either end. They may be stopped at any desired point in their travel, and thus the locomotive may be run at any speed with the same facility and economy of a steam locomotive. Forced ventilation is used with the auto-transformers and induction regulators as well as with the motors, the necessary air being supplied by suitable motor-driven blowers. Motor-driven air compressors are also used.

The locomotive is designed for slow-speed freight service, this type having been chosen because the design of series alternating-current motors for very slow-speed service presents many more problems and is much more difficult than the design of equal capacities for the ordinary conditions. This problem having been solved, the production of similar locomotives for passenger service becomes a relatively simple matter. With the motors working at nominal full-load output the locomotive will develop a draw-bar pull of 50,000lb. at a speed of approximately 10 miles per hour. On several occasions, however, when hauling the 50-car train referred to above, steady draw-bar pulls of from 60,000lb. to 65,000lb. have been recorded on the dynamometer car, and momentary efforts as high as 100,000lb. have been obtained with no sign of slipping of the wheels. With lighter loads the locomotive may be run at higher speeds up to a maximum of about 30 miles per hour.

The successful completion of so large and powerful an alternating-current locomotive without the usual series of developments through gradually increasing sizes, which is ordinarily required when so great a problem is undertaken, marks a distinct advance in the production of electrical apparatus for heavy traction work, and now that the first important step has been taken should certainly prove the forerunner of the use of electric traction on main-line railways which has so long been looked for.

THE ACADEMIC SIDE OF TECHNICAL TRAINING.

Prof. Alexander B. W. Kennedy, LL.D., F.R.S., whose name is included in the birthday list of new knights, on the 29th ult. delivered the foundation oration on "The Academic Side of Technical Training" before the University College Union Society, the president of the union, Mr. Scott, M.R.C.S., being in the chair. After giving details of the movement from its inception, Prof. Kennedy dealt with the progress made since his appointment as professor of engineering at the college in 1874, and said:

In 1874 the professor of engineering at University College—and this practically applies to similar chairs elsewhere—had to do not only with the work which is at present done here by Prof. Harcourt, Prof. Fleming, and Prof. Cormack, but practically the entire work of all the assistants of all these professors, for I doubt if an assistant to a professor of engineering had ever been heard of before that date. (My first classes had, I think, from three to six members.) Now, of course, engineering teaching generally is systematised and subdivided to an extent only comparable with the similar arrangements existing in connection with medical studies. If anybody is in the least interested in seeing what an unfortunate professor of engineering was expected to know in 1874, I recommend the study of the calendar of University College for that year. I look back upon the engineering prospectus which I drew up myself, following very much the lines previously laid down by Prof. Fuller, with wonder and amazement that I should have ever ventured to talk about so many different subjects, and with much admiration at the way in which I must have stood the after-lecture cross-examination by my students, who, after all, were not so very much younger in those days than myself. It was the sort of thing that could only have been done by a young man whose enthusiasm was not tempered by discretion, and it is no wonder that at that time candidates for such engineering chairs were not plentiful.

Now, all the great engineering societies have recognised formally that no engineering training is complete without its academic side, and a very important committee, consisting of delegates from the five great engineering societies, with Sir William White as president, has been at work for some time formulating their ideas as to the nature of the qualifying training, and going so far as to formulate also ideas as to the preliminary education of young engineers before they commenced their academic training. I do not wish—or rather I do wish very much, but it is not my subject to-day—to enter upon the very thorny questions involved in what that preliminary education ought to be according to the notions of a grown-up engineer. I will say, however (for it is no secret), that communications received from many headmasters of our great schools, while not going so far as some of us would like, are yet quite astonishingly radical in their ideas as compared not only with 30 but even with 15 years ago.

As to the general trend of our academic training, I think we engineers are entitled to say that it should be so arranged as best to train the best engineers. I put it in this way because I mean it to be understood that while on the one hand the *best* engineer is certainly not the man who knows his own business only and narrowly, on the other hand, I think we are entitled to demand that the engineer should not be looked upon as the mere by-product of the training, but as the chief result to which other things are to be subordinated. I think that University College is not likely to fall into this mistake, but the point has really to be kept in mind in cases where, as here, the engineering education is only one branch of the wide range of education covered by the whole work of a university college.

In saying this, however, I particularly do *not* mean that the academic training of engineers should be laid out exactly on superficially utilitarian lines. The idea of giving a young man just as much mathematics, just as much physics, or just as much chemistry as the minimum that he can professionally require is not only pernicious, but absolutely fallacious. There is no doubt that the only way of knowing a subject up to a certain point in such a fashion that, up to that point, it can be thoroughly utilised, is to study the subject up to some point very much further advanced. It is not at all a valid objection to the teaching of any particular point in mathematics or physics that it is more complicated or more advanced than anything which the engineer will be likely to require in practice. That, in itself, is not an objection at all, because, as I have said, it is impossible really to master a scientific subject up to a certain, often very elementary, point without having at least a superficial knowledge of a much greater extent of the subject. But it is desirable, indeed necessary from our point of view, that the advanced work in purely scientific subjects should be specially chosen so as best to deepen and make certain the knowledge of the earlier work. This may be, and almost certainly is, a very different thing from choosing it so as to form the best basis for still further study of the particular science in question. In this connection I must point out, at least as my opinion, that it is a mistake to consider that there is only one mathematics or one physics, and that either the preparatory work or the whole teaching must necessarily be the same for everybody—for the man who is to devote himself to engineering, or for the man who intends to spend his life in physical work. For instance, I think an engineering student may be allowed to take for granted that A times B is equal to B times A (he is always quite prepared to believe it), and that it is perfectly reasonable to make to him dogmatic and probably quite erroneous statements as to atoms (let us say), or as to the ether, without any of the qualifications which would be necessary supposing the atoms and the ether were to form the basis of the man's future studies.

It is, no doubt, a noble conscientiousness which sometimes prevents a man who is in the front rank among scientists from making to his students, as quite general, statements which he knows to be true only with qualifications or limitations. But the case is one in which often the general statement, given with authority, will really give the student a truer conception of the facts than a more accurate statement which is guarded by reasoning and explanation which he—that is, the student—cannot understand and will almost certainly misunderstand. As a writer in *Nature* put it a few days ago, referring to the theory of quaternions, "the truth is that very few students are able to appreciate to the full an absolutely logical argument until they have a certain amount of practical knowledge imparted to them more or less *by authority*."

I can illustrate this easily at my own expense. Years ago I read Sir Archibald Geikie's "Scenery of the Highlands" for the first time with great delight. Meeting Prof. Bonney in the common room soon after, and knowing of the existence of certain geological controversies, I asked him (perhaps more or less maliciously) if I might take Geikie's geology as all right. He hesitated a moment, and then said emphatically, "It is quite right enough for *you*, anyhow."

I have no doubt that Prof. Bonney's way of putting the matter was the perfectly legitimate one; it is exactly the point which I wish to emphasise, and I quote my old friend (although at my own expense) as indicating exactly the position which a scientific man is entitled to take up, and will wisely take up, in dealing with students to whom his subject is in effect only a secondary one.

There is one matter in connection with the teaching both of mathematics and physics to engineering students which I think might well be emphasised more than is generally the case. Whether it is desirable that it should be emphasised in dealing with the general student, I do not venture to say. I mean the point that the answer to any question can only be as accurate as the data of that question. For the ordinary examination question in mathematical physics it is necessary and unavoidable to presuppose certain data, which in real life are absurd and impossible. In the ordinary everyday questions of engineering there is nothing more misleading than to take for granted the data of the examination paper; and a very great deal of the disrepute into which mathematical work had fallen at one time

Digitized by Google

among engineers was due to the fact that although the average student was able to use his methods rightly, he was unable to perceive whether they led him to a right result. I think it must be possible, even if it is not exactly easy, to point out to the student the extent to which the accuracy of his answers is influenced by the assumptions which he makes. It is, I am afraid, too often presumed that the method of working out the answer is the chief thing; perhaps it may be from some particular point of view. But for our purposes, foolish as it may sound the method of working out the answer is only secondary; the answer itself is the chief thing, and we really *must* have that answer right when it finds itself translated into steel or stone. We would much sooner have a right answer got by an imperfect method than a wrong answer got by the best method in the world. And an answer may be wrong in two ways; it may be wrong because the data are in themselves wrong—that is to say, inapplicable to the particular case—or it may be wrong by being stated in a form much more accurate than the real data will allow of as when we find the indicated horse-power of engines given to six significant figures, when we know perfectly well that the fourth must always be doubtful. It would be most useful if our scientific professors would discuss these points with their students, and show them specially the extent to which the methods and theorems of the mathematician and the physicist may be properly applied when the only data available for the problems are such as actually are found in practice. It is hardly fair to leave the engineering professor to tell his pupils — or to leave the engineer to tell his assistants—that the methods they are using are quite inapplicable, and the results which they are getting obviously inaccurate. This is in every way inadvisable, and may lead the otherwise guileless student to discount all his teachers instead of only one! Every scientific experimenter knows that it it is often the most difficult part of his work to say how alterations in data or want of knowledge of accuracy in data may affect the result, and I should like much to see this matter systematically dealt with by the teachers who have actually to do with the scientific or theoretical treatment of the questions concerned. If they have any doubt as to what is the general nature of the complex engineering questions which have to be solved, a letter addressed to any engineer in Westminster would bring them the fullest information. But happily most of the university colleges now have engineers on their senates, so that the information can be had without going outside their own walls.*

I do not intend to say anything here as to the preliminary part of the academic teaching of specially engineering subjects, including laboratory work. This may be subdivided in many ways according to the individuality of the teachers, the arrangement of the staff, and the aims of the particular college, and it cannot be said that any one way is necessarily better than any other.

But as to the more advanced part of engineering teaching in colleges, I want to put forward an idea that I have more than once had occasion to express. I should much like to see the development of some such connection between old and distinguished students of a college—who become later on older and more distinguished engineers—and the college at which they have studied or some other college, as exists in the similar case of the medical profession. I do not mean simply, or indeed at all, that, for example, University College should ask senior engineers in the country or in Westminster to give occasional lectures to their students on special subjects. I do not say that such an arrangement may not be useful as an accidental or occasional thing, but I mean much more than this. The senior engineer (I am afraid I come into this category myself now) may have a very large experience and have carried out a great deal of work, but he is probably not in touch with the college or with academic work of any sort, nor in touch with students at all; and, therefore, while he knows his subject, he may be a very unsatisfactory teacher. There are two difficulties in an older man going straight from business to lecture. One is that, being out of touch with students, he does not understand the difficulties which present themselves to young men and which have so long ceased to be difficulties to himself that he has even forgotten their existence. Then, secondly, having been for many years accustomed to look at his professional work entirely from the non-academic side, he really knows too much to be able to lecture about anything. He would be too apt to overload his lectures with masses of, no doubt, very important statements, which would not be appreciated by men in the student stage, and which by themselves would also probably involve difficulties of apprehension, which would make their mere statement to the student useless—a condition of affairs exactly comparable with that which I have already deprecated upon on the scientific side of the work. My suggestion is that to get the full benefit from its best pupils, a college should, if possible, keep in touch with them after they have left it. A few years after they have left college, and when they have fairly got into the swim of professional work—but before they have so much lost touch with the difficulties of their college days that they no longer appreciate the student's point of view—they might be made to help in teaching by giving lectures on the special branches of engineering with which they were specially and actively familiar. They should do it before they have forgotten what they formerly learnt, or have had it driven out of their heads by the pressure of other ideas, and while college methods and points of view are still familiar. They would be men still making their way in their profession, still, let us hope, full of enthusiasm for their work, and certainly they would be daily finding out the differences between actual and academic problems. Teaching of this kind could in no way replace the general preliminary teaching of engineering subjects in the college, which must continue to be given, as it is given now, by a professor, or professors, the bulk of whose time is spent at the college and who are thoroughly in touch with all the students. I confess, however, that I hope a time will come when in any case professors of engineering will not remain permanently in academic harness, but will come out and take their place—a most important one — as colleagues among the active and leading engineers of the country, and will look upon such a position as that which they ought to reach rather than a solely academic position, however eminent. But, in addition to the work of the permanent professor or professors, I believe that old students coming back in the fashion I have indicated, not in one only but in several branches of engineering, and giving short courses of special lectures to third-year students, would very much help both the students and the rest of the teaching staff. The arrangement would also have the very great advantage of bringing about a closer and warmer connection between the men who are at work in their profession and the colleges where they were trained. It would also help to keep the colleges themselves in that actual and continual touch with engineering things and ideas which is so absolutely essential for their continued usefulness. The growth and development of engineering, as of all things technical and industrial, is so rapid, so varied, and so continually ahead of all text-books, that without personal contact of professors and teachers with actual work the teaching of a college may, indeed must inevitably, soon fall behind and become out of date. For this reason I have strongly advocated, in certain recent cases where I have been asked the question, that not only should a professor of engineering be allowed to carry on the real practice of his profession (I do not mean the giving of expert evidence) conjointly with his academic work, but that he should be encouraged and pressed to do so. This may result in the teacher giving up professorial for professional work altogether sooner than he would otherwise do. But if so, the students who have passed through his hands are certainly not the losers, however much the college may regret the loss. And no doubt the more it is found that the academic position forms a step in the professional, the more and the better candidates will be found for each academic vacancy which occurs.

It will be noticed that the scheme I have outlined is closely analogous to the system already general in connection with medical training, where the lecturing and professorial staff on the technical side consists almost entirely of old students (occasionally from other colleges) who are beginning to make their way professionally, or who, by the time they have become professors, have actually made their way to the highest ranks of their profession.

In conclusion, I will only add that I can hope for nothing better than that during the next 30 years—at the end of which I fear I cannot expect to be again asked to lecture here—the advance in the academic side of technical training may be as great and as real as it has been during the last 30 years, and that then, as now, and as in 1875, University College may in this matter hold the advanced position which it has always tried to maintain and deserve.

Lord RAYLEIGH, in seconding a vote of thanks to the lecturer proposed by the CHAIRMAN, spoke in highly eulogistic terms of the practical value of the address. As an illustration to show how much the efforts of the engineering departments in English university colleges were appreciated, he quoted the fact that the Indian Government had ceased to take their engineers from Cooper's Hill, but had taken them in what he called the open market, and with better results.

Subsequently, Prof. Vernon Harcourt, for 23 years engineering professor at University College, was presented by the students on his retirement with a magnificent silver bowl suitably inscribed.

* I should like to add here my great appreciation of such work as has lately been done by Prof. Karl Pearson in the publication of his "Research Memoirs." There is no scientific worker, as I had much occasion to know personally, who is more thoroughly alive to the points which I have just raised than my old and most distinguished colleague, the value of whose recent investigations has received such cordial recognition from the most practical of engineers.

PERSONAL.

Mr. Albert E. Armstrong, of Willington-road, West Hartlepool, who was apprenticed to Messrs. Richardson, Westgarth, and Co., of the Hartlepool Engine Works, and Messrs. Brown, Boveri, and Co., of Baden, Switzerland, has been appointed chief electrical engineer to the Wahai Grand Junction Gold Co., New Zealand, and his first duty on arrival will be to supervise the erection and working of three sets of turbine electrical machinery, just completed at the Hartlepool Engine Works.

The successful candidate for the post of chief assistant electrical engineer at Battersea is Mr. P. MacAlister, who formerly held the position of mains superintendent there.

We regret to learn that Mr. Alexander, electrical wire inspector under the Swansea Corporation, met with a serious accident whilst repairing a wire on a raised trolley. One of the wires was carried away and struck him on the forehead, precipitating him a distance of about 20ft. to the ground.

Mr. Hamilton Kilgour has resigned the position as borough electrical engineer of Cheltenham.

We understand that the Southampton Corporation have increased the salary of the electrical engineer, Mr. H. F. Street, by £100.

Mr. Ernest T. Williams, chief electrical engineer, Gibraltar, and formerly of Belfast and Salford, was married on July 5 to Miss M. C. Catleigh, only daughter of R. Catleigh, Esq., of King's Lynn.

The Leeds Council have increased the salary of Mr. G. E. Watmough, tramway car works superintendent, to £250 per annum.

SYSTEMS OF CHARGING.

Municipal engineers have had during the past fortnight several opportunities of discussing the charges made for the supply of electrical energy. At the meeting of the Incorporated Municipal Electrical Association in Scotland five out of the six papers read dealt more or less closely with this subject. Then came Mr. J. H. Rider's paper before the annual conference of the Municipal Tramways Association of Great Britain on Tuesday last on "Charges for Supply from Combined Lighting and Traction Stations." This final contribution to a well-worn subject is remarkable for the clear way in which the cost of producing electrical energy for various purposes is analysed so as to give a true basis for differential charges. The need for such a paper is proved by the discussion which followed. Mr. Rider's text was: "Can a combined station sell electrical energy to a tramway as cheaply as the tramway can produce its own?" The tramway managers who spoke treated the matter as though the word "can" was replaced by "do." They then answered this query in the negative, and strongly advocated separate generating stations for tramways. We were pleased to see that many of the chairmen of tramway committees who were present looked at the subject in quite a different light, and recognised the advantages of having a common generating plant to supply all the electrical energy needed within a given area. The essential difficulties in the matter are two. The first is that of fixing the charges on the maximum demand system in each town. The limit of eightpence per unit fixed by Parliament is the most that can be demanded, and there is no doubt that this charge made for a short period of average daily use is the correct way of ensuring that each consumer bears his share of standing charges. If this is adopted, and a very low rate equal to the real running expenses is made for the additional consumption, an equitable system is secured, which will encourage an extensive use of electrical energy for all purposes. The first difficulty being then solved, the second has to be met—that is, failure of consumers to recognise the equity of the above system. This was apparent from the discussions at the Edinburgh convention. Speaker after speaker said that the maximum demand system would have to be abolished because the users of electricity could not understand it. They also said that a flat rate must be adopted, but in nearly every case it was clear that a series of flat rates was contemplated. These were to be fixed on the basis of the average cost of supplying each class of consumer with due regard to their average load factor. We are not surprised that the maximum demand system does not meet universal approval amongst small lighting consumers, but looked for more appreciation of the same from tramway managers. These gentlemen are daily confronted with problems on parallel lines. Thus their costs of being ready to carry passengers are heavy, outweighing the actual cost of doing so. The cars, to meet the morning and evening rushes, have to make one journey with practically no passengers on board. If passengers for these journeys could be found, the cost per car mile would scarcely be altered, but the revenue per car mile would be nearly doubled. This would enable fares to be reduced, just as the maximum demand system enables long-hour consumers to get electricity at a very low rate. We trust that tramway managers will read Mr. Rider's paper carefully, and that the result may be less bickering over the charges they are called upon to pay from combined stations. The engineers of these stations need to verify their allocations of costs, and if this is done each year, there cannot but be advantages from the single supply to all concerned. Example in these matters is better than

Digitized by Google

any theoretical discussion, and the case of the North-Eastern Railway Company should convince the doubting tramway managers. If a power company which looks to make a profit out of the supply of power can, by reason of its diversity of loads, sell energy to a large railway company more cheaply than they can produce, there should be little opening for separate tramway stations.

MUNICIPAL TRAMWAYS ASSOCIATION.

FOURTH ANNUAL CONFERENCE.

Presidential Address.

BY ALFRED BAKER, GENERAL MANAGER, BIRMINGHAM CORPORATION TRAMWAYS.

Gentlemen,—I have, in the first place, to congratulate the members of our association on its continued usefulness and prosperity. During the past 12 months many matters affecting tramways and light railways have had consideration, and on more than one occasion we have been able to express our views and to make representations which have been attended with happy results. In numbers we have not had such a large accession to our ranks as Mr. Bellamy, our late president, was able to report during his year of office. This, of course, was accounted for by the fact that our association already comprises nearly all the corporate bodies and individuals entitled to join under its existing constitution. Our present membership numbers 55 corporations and 82 managers and principal assistants. We represent in capital expenditure upwards of 21 millions of money; our cars run 113 million miles per annum; and we carry more than 1,100 million passengers every year. The managers' section of our association, following the usual custom, has during the year held meetings for the discussion of useful and interesting papers on matters pertaining to the operation of tramways. The meetings this year were, through the kindness of the Lord Mayor, held at the Council House, Birmingham, and the members were very graciously welcomed to the city by Mr. Alderman Beale, J.P., chairman of the Tramways Committee of the City Council. I am convinced that the managers and their assistants appreciate the opportunity afforded by these sectional meetings of comparing notes on technical matters and points of general interest.

Municipalisation in America.—Perhaps the most striking feature of the year, certainly one that has caused most widespread interest in the tramway world, is the announcement that the great city of Chicago has declared, by a majority of upwards of 25,000 of its citizens, in favour of the municipalisation of its street railways. It has been a very common thing for the opponents of municipalisation of tramways to point to America in their endeavour to show that better results can be obtained from private than from public enterprise. They have always asserted that the American citizens were far too "cute" to undertake municipal ownership. Now, no one denies the "cuteness" of the American, but it must be remembered that civic life in America is comparatively young, and it seems to me to be a sign of national good sense that, as opportunity arises, America is not above taking a lesson from this country. Chicago is a city with an enormous mileage of privately-owned lines. It has been estimated that the cost of purchase cannot be less than eight million pounds. The City Council is, therefore, face to face with the gigantic task of co-ordinating the various systems with a view to giving the city one complete scheme of tramways under proper civic control. It is characteristic of our cousins that, having once decided on a course of action, they have begun in no half-hearted manner in tackling what is, perhaps, the biggest thing in tramways in the world. In was little thought eight or ten years ago that the United States was likely to find an object lesson in tramway management in this country. Yet such has proved to be the case. The striking success of municipal ownership and operation in the great cities of the United Kingdom—London, Glasgow, Liverpool, and Manchester—with their cheap fares, efficient services, and large profits, has long been the astonishment and envy of the civic authorities across the water. Now that Chicago has set the example to her sister cities, we shall doubtless be hearing of widespread municipalisation throughout America. Indeed, San Francisco has already won two elections in favour of municipalisation of its public utilities. In the early history of electric traction we had to go to America for all our knowledge. It speaks much for the engineering talent of this country that there is now no need to copy the United States any longer. It is generally acknowledged that, so far as the construction and equipment of tramways are concerned, we are not now so far behind—indeed, many people are of opinion that we can give points. However, whether this be so or not, we are grateful for what America has taught us in the past, and if our municipal experience is of any value to Chicago or any other American city, we shall be glad to place it at their disposal in the fullest and freest possible manner. Before passing from this subject, I think we may heartily compliment Glasgow on being invited to teach Chicago something of the art of successful municipal ownership and operation of tramways.

Carriage of General Merchandise.—Those of you who had the good fortune to be present at our annual conference held in Liverpool last year, and of listening to our late president's most excellent address, will readily recall some of the large number of points he touched upon and dealt with in such a skilful and interesting manner. Mr. Bellamy's remarks covered such a wide field that I find it somewhat difficult to deal with the subject of tramways and light railways without going over again some of the ground he traversed. It will be remembered that amongst the most striking features of that address was the allusion to the possibility of linking up urban districts with rural districts by means of tramways and light railways for the purpose of general merchandise traffic, and the suggestion that our association might effectively demonstrate its general usefulness by preparing a memorandum of a scheme for facilitating the provision of such means of conveyance in conference with the representatives of municipalities and county councils, for consideration by the Minister of Agriculture. This important matter has, I am glad to say, been under the consideration of your executive committee, who, however, are not in a position to lay any proposals before you at the present time. The subject is of such vast importance that every detail of a scheme of this character must be carefully thought out, so that no ill-considered proposal may be propounded. I sincerely hope during the coming year some such scheme as outlined by Mr. Bellamy may be formulated and action taken likely to bring it to fruition. Our association can, of course, only "outline" a scheme and place at the disposal of the authorities such technical and practical knowledge and experience as we possess.

Carriage of Parcels on Tramways.—A step in the direction indicated, although it is one limited to towns and suburban districts, has been taken by the inauguration in two or three of our large cities of parcel carriage services. These have been undertaken for the first time in the history of tramways on anything like a large scale, and with proper organisation for the carrying on of the business. It has, of course, been recognised for many years that tramways could be used for this kind of traffic with very considerable advantage and profit to the community. Nothing, however, has hitherto been attempted on quite the same scale as the system inaugurated with such marked success by the Manchester Corporation in April of this year. The use of electricity as a motive power has, of course, rendered a quick service of parcels carriage much easier of accomplishment than would have been possible under the old methods of traction, and we shall doubtless see in the near future very considerable development in this class of business. Primarily, tramways are authorised and intended for the carriage of passengers, and it is the first duty of tramway undertakers to give quick, efficient, and cheap services for this purpose. When this has been accomplished to the satisfaction of the community, it seems to me that if another branch can be conducted without interference with the business for which the tramways were originally intended (and this should be the first considera-

Digitized by Google

tion), the community have a right to demand that their lines shall be used to their fullest capacity in the public interest. That Parliament contemplated the use of tramways for goods as well as passenger traffic is shown by the fact that since the General Tramways Act of 1870 was framed nearly all the local Acts contained a schedule of charges for goods, parcels, and live animals—even to the donkey. The result of the working in Manchester and Bradford will be watched with the greatest interest by all who are concerned in the operation of tramways, and doubtless many of us will profit by the experience of these go-a-head cities.

Tramway Speeds.—I now come to a subject which has exercised the minds of those engaged in the operation of tramways for a considerable period. I refer to the speed at which cars are allowed to be driven upon tramways. In the early stages of electric traction it was difficult to get the Board of Trade to authorise a greater speed than eight miles an hour. This was the maximum speed at which the cars were allowed to travel. The average speed, inclusive of stops, was not much beyond that obtainable on horse tramways some 25 years ago. That the Board of Trade was right in exercising great caution in safeguarding the public when the new system of traction came into vogue no one will deny. As time went on, however, the equipments adopted for properly controlling the cars, both mechanical and electrical, together with the introduction of improved devices for saving the lives of persons falling in front of, or being knocked down by the cars, were of such marked improvement on those at first in use that it was felt the Board of Trade might safely grant increased speed over that originally allowed. Representations were made by the parties interested, and in some cases the Board of Trade were induced to grant a slightly increased rate of travelling. It is satisfactory to find that these concessions did not increase the number of accidents occurring in the places where the higher speeds had been obtained. In 1903 Liverpool, with its enormous traffic, was able to demonstrate, after a period of marked immunity from accident, that a higher speed than that allowed under the Board of Trade regulations could be safely granted, even in heavy city traffic, and it is satisfactory to know that the Board, after careful enquiry, felt able to give an increase of 25 per cent. over the rate of travelling originally permitted. In his report to the Board of Trade recommending these changes, Lieut.-Colonel P. G. von Donop stated: "Electric cars have now been running in Liverpool for nearly five years. The drivers are now very efficiently trained, and there has been of late a great freedom from serious accidents. Under these circumstances, I consider that an increase of speed might now be allowed." The general manager of the Liverpool tramways in his annual report states that the broad effect of the change is that while under the old regulations the average speed, including stops, was limited to 5·8 miles per hour, under the new regulations the average speed is increased to about 7½ miles per hour, and that, notwithstanding these changes, street accidents of all classes have considerably declined during the year. There are many members of our association who think that much greater facilities might still be granted in this direction, and I confess I am one of their number. When it is remembered that in one year the tramway cars in the United Kingdom ran upwards of 190 million miles, and that they carried 1,800,000,000 passengers, the number of fatal accidents reported is so small, that this, in itself, would seem a very strong argument in favour of a higher rate of speed. It seems somewhat anomalous that motor-cars and motor 'buses—vehicles that can wander all over the carriageway, and frequently do—are allowed a speed of 20 miles per hour, while tramcars, running on fixed lines from which they cannot deviate, are limited to a considerably less rate of travel. No one, of course, wants to get an authorised speed which it is impossible to make use of in crowded thoroughfares. Here the speed of the cars must to some extent be regulated by the density of the traffic, but in less populous suburban districts it is of the greatest importance that passengers should be transported at a quicker rate than is now permitted. Time is, of course, the greatest factor in the solution of the problem of urban and suburban communication. It is of no use projecting schemes for the housing of the working classes in the outskirts of our large towns and cities unless adequate means of communication are provided. The workman not only wants to be carried to and from his work, but he wants to be carried quickly, and without spending too much time on the road. The same thing applies to the clerk and to the business man, and I think our efforts ought to be directed in the first place, if we have not already done so, towards getting the most perfect equipments upon our cars to enable them to be kept under absolute control, and afterwards to use every endeavour to get our speeds increased to such an extent that we may give the public not only a cheap but a rapid method of transit. In concluding my remarks on this subject, I think I cannot do better than quote the head constable of Liverpool. In speaking at the Southport meeting of the British Association he said: "He considered that the faster the street traffic the safer it was. There had been a considerable decrease in accidents in Liverpool since the introduction of electric trams. The trams had educated all classes of the public in regard to taking greater care in the highways." This is striking evidence, and there is no doubt that the experience of Liverpool in this respect is common to other towns.

Motor Omnibuses.—The past year has witnessed what I may call a motor omnibus boom. Opponents of electric tramways, and especially opponents of municipal tramways, have seen in the coming of the motor omnibus the doom of electrically-driven tramcars. They have seen tramways in our great cities lying derelict, electric tramcars sold for base uses, such as bathing machines and hen roosts, and the millions of money spent in this country on tramway undertakings utterly wasted. A terrible picture surely, but fortunately the advent of the motor omnibus is not likely to leave such ruin in its train, whatever else it may leave behind. Tramway men have, of course, paid the most careful attention to the motor 'bus to find out whether it was likely to prove a useful adjunct to tramways in dealing with the great mass of traffic requiring to be handled in our great cities, but it did not take long to find out that, however useful the motor 'bus may be in some respects, and whatever advantages over a horse omnibus it may have, it cannot now and never will be able to compete successfully with an up-to-date electric tramcar. To quote the Hon. Arthur Stanley, M P, an ardent automobilist, and president of the Tramways and Light Railways Association. In addressing that association, Mr. Stanley said: "When anyone finds a cheaper mode of traction than a metal wheel on a metal rail, then tramways will be run off the road, but not till then." There, gentlemen, lies the crux of the whole question—viz, the cost of operation. Everyone interested in electric traction knows what it costs to operate tramways on a fairly large scale in this country. The figures are published year by year, and are well known even to "the man in the street," but the "boomers" of the motor 'bus are peculiarly reticent as to the working costs of the petrol-driven vehicle. The only figures yet published, so far as I am aware, are those in the weekly edition of the *Tramway and Railway World* for Feb. 7. These relate to the operation of the Hastings omnibuses, and are set out as follows: general repairs and tyres, 3 50d; wages of conductor and driver, washing 'bus, etc, 2 50d.; oil, petrol, grease, etc, 2 00d; all other expenses, including depreciation at 20 per cent., 3 50d.—total, 11·5d. per mile run. I understand that these figures are stated by the makers, and are not likely, therefore, to err through excess of caution. It has since been reported in the daily Press that the result of a year's working shows a very considerable loss. Now let us see how these cost compare with electric tramways. Taking six of the largest undertakings in the United Kingdom, I find that the total operating costs average 6·12d. per car mile. This figure includes power costs, traffic costs, maintenance and renewals, and general expenses. "Ah! but you must remember," say some, "that motor omnibuses have no permanent way to provide, whilst tramways are costly to maintain." Quite true; but taking the same six undertakings, I find that the interest and repayment of loans on the permanent way and overhead equipment amount only to another 1·036d. per mile run, so that, taking

Digitized by Google

even this serious item into consideration, there is still a difference in cost of 4·354d. per mile run in favour of electric tramways. It must never be forgotten—and tramway men are not likely to forget—that the cost of operating tramways includes very heavy amounts for rates on the tramway portion of the public road, while omnibuses pay nothing whatever, although they do considerably more damage. Of course, the principal item of expenditure in connection with motor 'buses is for indiarubber tyres. I am informed on good authority that these cost from 2 l. to 2½d. per mile run. Now, assuming a motor omnibus to be capable of running 90 miles a day, the same as an electric tramcar, you have for 365 days a total of 32,850 miles. This means in money for tyres, at 2½d. per mile, £342. 3s. 9d. Now, a set of four tramcar wheel tyres can be bought for £8. These will have on an average a life of 50,000 miles, which works out at a minute fraction of a penny per mile—to be accurate ·0384d.—so that what costs the motor omnibus £342. 3s. 9d. per annum, costs the electric car about £5. 5s. 1d. per annum. If one takes, therefore, a fairly large city, where, say, 100 vehicles are required in daily service to deal with the traffic, you have a difference in this one item alone of upwards of £33,600 per annum in favour of electric trams. I do not want to labour this matter, and I say nothing about the increased carrying capacity of tramcars as compared with motor 'buses. I think I have said enough to show that motor omnibuses are not going to supersede tramways, and that municipalities and ratepayers need be under no apprehension that the large amount of capital invested in their tramway undertakings is likely to be sacrificed.

Amalgamation.—Another matter which has been freely discussed of late, and one to which your executive committee has given a great deal of attention, is with regard to the advisability of amalgamating the three tramway associations—viz., our own association, the Tramways and Light Railways Association, and the Association of Tramway and Light Railway Officials—so as to form one single powerful organisation, which it is claimed would more adequately represent the views of all those engaged in the tramway industry. You will remember that originally we were formed as a municipal tramway managers' association. After a short time it was felt to be desirable to alter the constitution so as to embrace chairmen of tramway committees, and a proposal will be before you at a later stage of these proceedings to still further widen the basis of our association so as to admit vice-chairmen of committees as well as chairmen. With regard to amalgamating the three associations, there is much to be said in favour of having only one powerful body to watch over tramway interests, and if satisfactory arrangements can be made I see no objection to it. Municipal interests, however, must not be subordinated, and I, for one, would never be a party to any alteration in our constitution which would tend in the slightest degree in that direction. The matter, however, is under the consideration of your executive committee, who are giving the most earnest attention to the whole subject. Informal conferences have already been held with members of the other associations, but nothing will be done without the full sanction of the members of our association in general meeting. Now, with regard to our programme, last year it was found that we had more papers than we could properly digest. This year it has been felt desirable to limit the number so that we may give each paper full consideration, and also allow our members every opportunity of inspecting the exhibits of the manufacturers at the Tramways and Light Railways Exhibition in the adjoining hall. There the members will doubtless find much to interest them—many things that are up-to-date and novel.

Standardisation.—It is true that a great deal of the material now used in the construction and equipment of tramways has been standardardised by the British Standardising Committee, and in this respect something like order has been evolved out of chaos. There is, however, I think, a word of warning due here, lest, following the easy path of standardisation, we should, perhaps unconsciously stifle initiative and invention. Standardisation up to a certain point is good. It enables manufacturers to stock certain articles which long experience has proved to be in greatest demand. It also enables buyers to purchase, without themselves having to get out special designs, or to pay manufacturers for so doing, and this, of course, is a very considerable convenience. The point I wish to make is this: we must not accept as finality anything that happens to be standard, otherwise our engineers and inventors will become disheartened, and we shall become "sticks in the mud." I know inventors are sometimes somewhat of a nuisance, and trying to one's nerves and temper, but we may some day "entertain an angel unawares." It behoves us, therefore, to be on the look-out for the "angel" who can show us something even better than the standardised article, especially if it tend towards increasing our revenues or adding to the efficiency of the business in which we are all engaged.

I shall not detain you longer except to express the hope that this year's conference may be as interesting and instructive as those which have preceded it.

ELECTRIC TRAMWAY AND RAILWAY EXHIBITION.

The third International Electric Tramway and Railway Exhibition was formally opened by the Earl of Derby at the Agricultural Hall, Islington, N., on Monday last. A luncheon followed, at which Mr. James W. Courtenay, the chairman of the Exhibition Committee, presided. In proposing the toast of "The Industry of Transport," Lord Derby quoted some interesting statistics showing the enormous growth of the tramway industry during the past few years. The total number of passengers carried in 1878 was 146 millions, in 1898 the number had risen to 858½ millions, while in 1903-4 the tramways had carried nearly 1,800 million passengers.

Messrs. Babcock and Wilcox, Limited, whose stand is No. 13, have an excellent exhibit of models of their water-tube boilers, chain-grate stokers, water-softening apparatus, etc. They have also at the back of their stand one of their silent gravity bucket conveyors erected to show the details of construction. These conveyors, while specially designed for boiler-house work, carrying coal to the bunkers and ashes from the boilers, are also adapted for conveying other materials. The actual conveyor exhibited is capable of handling 20 tons of small coal per hour. The driving device is a very important feature of this conveyor, and may be actuated by any motive power obtainable. It consists of a spur-geared engine operating two sets of pawls, which successively thrust the chain in the direction of its travel, engaging with both sides simultaneously. By this device any wear in the chain links is compensated, and a chain works as freely and easily after years of constant use as when newly started. Another special feature of this conveyor is the application of free or revolving wheels where the direction of the conveyor is changed, either from the horizontal to the vertical in the same plane, or at any angle to the first plane of motion. In descending from an upper run to any depth the maximum stress is at the point of turning to descend, and here the wheels carrying the chain and buckets cease to rotate as soon as they touch the revolving free wheels, and when movement ceases friction also ceases, and, consequently, wear on the chain, wheels, and axles ceases also. The conveyor is practically automatic in its cycle of action, no handling being necessary from the point at which the material is delivered into the receiver hopper, until it is "discharged," further than moving the levers of the dumpers to fill up the sections on which it is desired to operate. The turbine tube cleaner is also shown on the stand, and there are some interesting specimens of special steam-pipe work.

Messrs. Bruce Peebles and Co., Limited, of Edinburgh, show on their stand No. 48 a considerable amount of novel apparatus for electric traction purposes. Their exhibit, in fact, gives some practical examples of the steps which the firm are taking to develop alternate-current traction on the latest lines. They have on view a standard tramway motor and controller for direct-current working as well, but visitors will be mostly interested in the newer type of plant for three-phase and single-phase working. Amongst these we specially noticed the continuous-current three-

Digitized by Google

phase traction equipment which has been built for the Canadian South-Western Traction Company, of London, Ontario. The exhibit consists of a truck fitted with two 135-h.p. motors. This company operates an interurban line some 30 miles in length, which is being equipped by Bruce Peebles and Co., Limited, on the three-phase system at 1,100 volts. In order, however, that the cars may be able to run into the city of London, which has an existing 500-volt service, it was necessary that the motors should be able to run on continuous current, and they have been designed accordingly. The motors have a distributed winding similar to that of an ordinary three-phase induction motor, and an armature with both commutator and slip-rings wound similarly to a series-wound

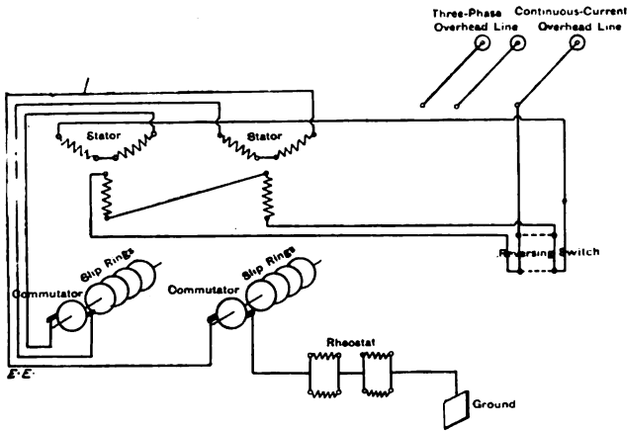

FIG. 1.

continuous-current armature on the two-circuit principle. When running on continuous current, the motors are controlled in the same way as a pair of standard 500-volt traction motors. When running on three-phase current, however, the brushes are lifted off the commutator from the driver's stand, and the motors are started in cascade, and afterwards cut into parallel, giving the same character of acceleration as with two continuous-current motors in series-parallel. Through the courtesy of the firm, we are able to give the accompanying illustrations to show how the motors are connected for the various methods of operation. Thus, Fig. 1 shows the connections when the motors are worked on the continuous-current supply and connected in series. Fig. 2 shows the connections on the

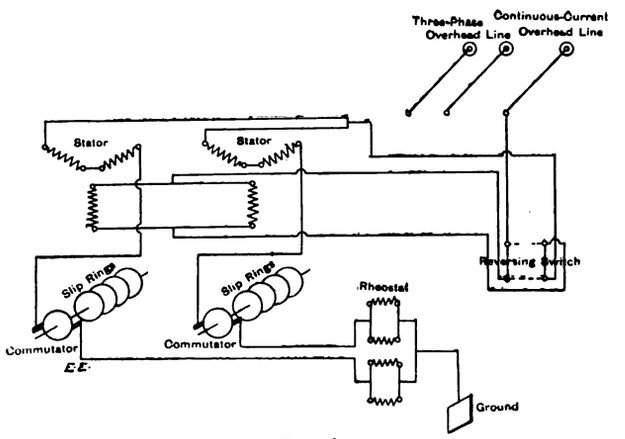

FIG. 2.

same supply with the motors in parallel. When the truck is running on the interurban line with three-phase currents, the cascade connections are as shown in Fig. 3. It will be seen that in this case the two rotors are connected in cascade, and that the regulating resistance is inserted in the stator circuits of the second motor. Fig. 4 shows the connections with the two three-phase motors in parallel. In this instance the regulating resistances are placed in the rotor circuits, which are wound on the two-phase system. The reason for this is that the resistances required for direct-current working can be more conveniently utilised with a two-phase winding. The design is such that one controller works the motors on whichever system they are run. The brushes are lifted off the commutator when the motors are running on the three-phase line, but the brushes on the slip-rings are never lifted. When this equipment is at work in Canada, some interesting figures will be obtainable as to the economy of the system. The three-phase motors allow of a considerable amount of energy being returned to the line on down grades when braking.

On the same stand there is to be seen a three-phase locomotive which has been built for the Portmadoc, Beddgelert, and South Snowdon Railway. Nine other locomotives of similar design are in hand. The motor has a vertical shaft, owing to the difficulty of fitting so large a motor on to the narrow gauge of 2ft. The locomotive as shown is capable of hauling loads of 50 tons up gradients

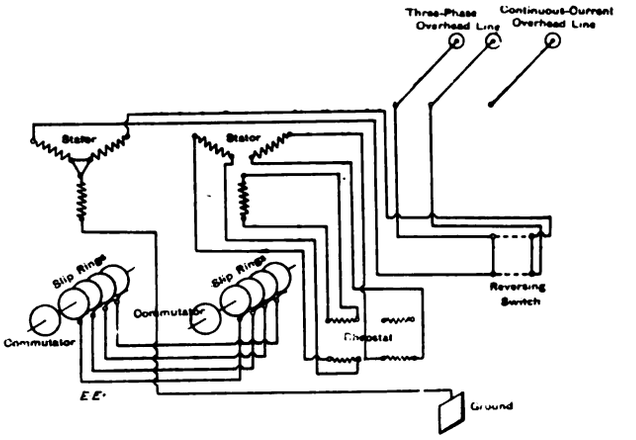

FIG. 3.

1 in 40, and it can also attain a speed on level of 25 miles an hour. The normal horse-power of this locomotive is 100, but the motor can be worked up to 250 h.p. for short periods. One feature of the design is that the weight is kept low, and the power developed is high for such a small-gauge locomotive. The single-phase traction motor on this stand has been constructed under the Peebles-Arnold-LaCour patents, and is of the compensated repulsion type. It is claimed that the efficiency, power factor, freedom from sparking, and economy of current consumption achieved by this motor constitute a record in this type of machine. It differs from the Latour motor in that three brushes only, instead of four, are required with the bipolar arrangement.

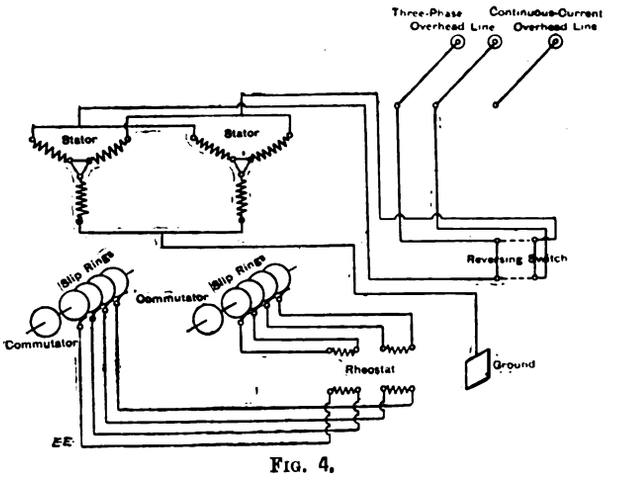

FIG. 4.

The motor exhibited is capable of, approximately, 80 h.p., and has six poles, five brushes only being used. The firm also exhibit a 400-kw. motor converter for converting 6,600-volt three-phase current into 550-volt continuous current. This converter, which is built on the Peebles-Bragstad-LaCour patents, combines the advantages of both a rotary converter and a motor-generator, and, at the same time, it avoids the disadvantages of both these machines. The firm have a large number of orders going through for these converters.

Messrs. Dorman and Smith exhibit a long range of their grip-contact circuit breakers, and they are showing a new design of time-limit tripping gear for use in connection therewith. This device seems to fill every requirement of

Digitized by Google

central-station practice. It is a relay arrangement to close an auxiliary circuit to automatically open the circuit breaker on any overload that would cause injury through rise of temperature in the circuit controlled. The period of time introduced by the time-limit device is inversely as the amount of the overload, ranging from over five minutes for very moderate overloads to about seven seconds for excessive overloads. The circuit breaker when used with the time-limit device is wound so that it will instantaneously

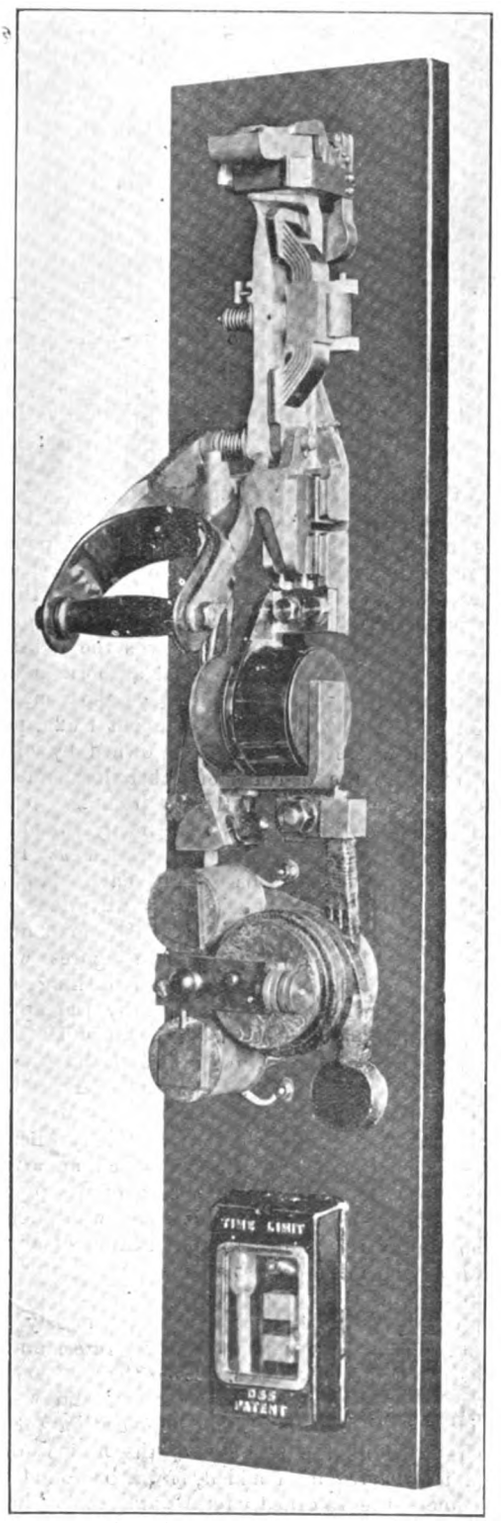

FIG. 5.—Dorman and Smith's "Grip Contact" Circuit Breaker, combined Overload and Reverse Current form, with D. & S. Time Limit Device.

open the circuit if subjected to any overload that would cause mechanical injury: thus the time-limit device can be set to operate from 50 to 300 per cent. overload, and the circuit breaker itself will operate instantly when the current exceeds 300 per cent. of the normal rating. The values can be varied if desired for special purposes. The illustrations (Figs. 5 and 6) which we give of the time-limit apparatus are easily understood without a long description. It will be seen that a certain portion of the main current is used to heat one bulb of a U-tube containing mercury. This causes the mercury to rise in the other leg of the tube and to close the subsidiary circuit which actuates the tripping device of the circuit breaker. Visitors interested in circuit breakers would do well to look closely into the grip contact employed by this firm. It will be found that when the switch is closed, the contact faces are gripped together firmly. On releasing the trigger the lever grip is released and the switch is opened by the powerful spring plunger, the pressure of which was previously exerted to keep the contact faces gripped together. The advantages of this method of construction are: (*a*) the contact faces are kept clean by friction, when opening and closing the switch; (*b*) the gripping device ensures cool working, when the switch is closed; (*c*) the releasing of the "grip," when the trigger is operated, ensures the switch opening with certainty under all circumstances. This series of circuit breakers are also arranged with a secondary switch, which is closed after the primary switch; the latter is then independent of the operator's hand and is free to open immediately. The firm exhibit one of their circuit breakers for three-phase working, in which two of the tripping devices operate on overload in two of the phases. The third switch is controlled by a no-load device. All three switches are simultaneously opened if either of the three devices acts. At the back of the stand a handsome

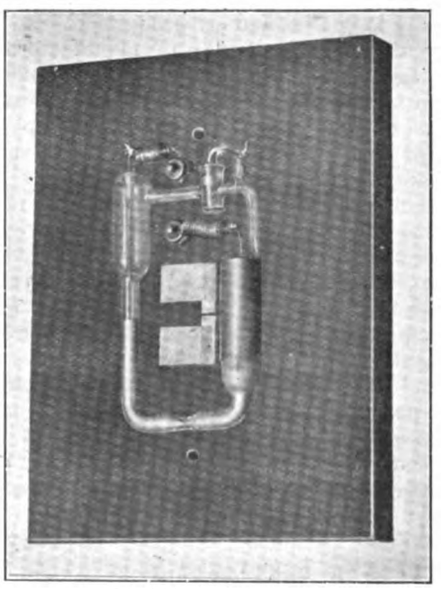

FIG. 6.—Dorman and Smith's Time Limit Relay (cover removed).

traction switchboard belonging to the Swansea Corporation is on view.

The Brockie-Pell Arc Lamp, Limited, exhibit on Stand 146 their latest form of enclosed type of arc lamp, which has been recently introduced. They have also on the stand a number of the Newcastle type of lamp, which have been largely used in connection with the street-lighting from the tramway poles in that city. These lamps are of the double-carbon open type, and burn for 36 hours with one trimming. They are shown in the central carriers as used in the above-mentioned city, and also at Brighton. We understand that the company have a flame arc lamp which will be on the market at a very early date.

The British Electric Equipment Company show a variety of fittings for the overhead trolley system which should meet every possible contingency. In the whole series the insulation used is of the "Dirigo" type, which is remarkable for its stability, and for the fact that it is absolutely non-absorbent of moisture. The Nicholson patent frogs and crossings are exhibited, and these will be found specially suitable where swivelling trolleys are employed. Visitors to the exhibition would do well to get a special bulletin issued by the company describing their new type of bond, which they have christened the "soldered bond." Their latest apparatus for sanding tracks worked by pneumatic pressure is also worthy of careful inspection.

The Electrical Power Storage Company on Stand 113 have some very large secondary batteries on view. Amongst these is their O L 74 type, which has a capacity

Digitized by Google

of 5,000 ampere-hours when discharging in one hour, or 10,000 ampere-hours when discharging over four hours. To get this large capacity, two sets of plates are placed in the one containing vessel. The mechanical details of the cell are worthy of special inspection, and the arrangements are such that the cost of upkeep should be reduced to a minimum. They have also an O K type of cell with 53 plates on the stand with a capacity of 5,200 ampere-hours on a four hours' discharge. Either of these cells are suitable for heavy traction work The smaller batteries used for electric vehicles are also well represented. For instance, one box contains 44 cells of the A B 15 type, which have a discharge rate of 30 amperes over five hours. The weight is as low as 30lb. per cell complete with acid and ebonite containing vessel. The plates in these cells are divided by perforated ebonite separators with rubber ribs, which tend to prevent any damage being done by vibration. The other sets of automobile batteries exhibited have a smaller capacity. Accumulators for ignition purposes are also well represented.

The Electric Tramway Equipment Company, which have their headquarters at 86, Glover-street, Birmingham, have a general exhibit, comprising overhead line material, switchboards, and gear and pinion wheels of a number of standard types. The gear wheels in question are machine-cut from individual hammered forgings of Siemens-Martins open-hearth steel. The pinions produced in this way have an exceptionally long life, and by production with automatic machinery the labour charges in manufacture are kept down to a minimum. We understand that one of these pinions can be machined complete in a little over an hour. In the overhead line material the "Verus" type of insulation is used throughout, and some interesting special types of insulators made of this material are on view. Amongst these is a half-globe insulator, which is exceedingly useful where the space is so limited that the ordinary globe strain insulator cannot be employed. An exceedingly large range of ears is shown, there being 70 different types manufactured by the firm, varying in length from 7in. to 42in. Amongst the switchgear we noticed a number of section feeder panels, amongst which was one of the type now largely used by the British Electric Traction Company. In the construction of these, double insulation between the iron of the section pillar and the live metal of the switchgear is everywhere provided. Specialities for use in connection with surface-contact systems are also exhibited by this firm

The Berliner Telephone Company naturally introduce into their exhibit a large variety of telephone equipments for use in connection with tramway undertakings. Amongst these there are complete equipments for feeder pillars and a series of portable telephones which can be used in connection with plugs in such pillars. Amongst these is a portable breakdown telephone set, which will appeal to tramway engineers. A water-tight bell which will be of considerable service for exposed positions is also interesting. In this the mechanical motion is transmitted from the electromagnet to the gong through a thin metallic diaphragm, which effectually seals the mechanism of the bell against moisture or dust.

The Aron Electricity Company, Limited, on Stand 138 have a historic collection of meters, ranging from the earliest Aron type up to the latest production of this firm. Amongst the newest instruments we noticed a continuous-current meter, with which was combined a maximum demand indicator. This indicator was in the form of a dial at the top of the meter, and gives a reading directly in watts. In the instrument we inspected the maximum consumption in any period of 10 minutes was indicated by this pointer. This was done in the following way: The pointer was connected by means of a gear wheel to one wheel in the counter-train. This gear wheel was drawn out of gear at 10 minutes' intervals, and working against a spring returned to the zero position. The pointer being loose on the shaft is not returned to zero by the spring, and thus registers the maximum amount recorded in any interval of 10 minutes. The demand indicator being direct reading is exceedingly convenient, and it is also well to have a meter and demand indicator combined. An alternate-current motor meter for the two-rate system is also on view. A large number of meters suitable for tramway work were to be seen on the stand.

CHARGES FOR SUPPLY FROM COMBINED LIGHTING AND TRACTION STATIONS.*

BY JOHN HALL RIDER, M.I.C.E., ELECTRICAL ENGINEER, L C C. TRAMWAYS.

In 1896 the author read a paper before the Municipal Electrical Association advocating combined lighting and traction stations. The principle was laid down that where the lighting and tramway undertakings were in the hands of the same authority, the supply should be given to both from the same generating station. There are now about 114 such stations at work, some being originally lighting stations with tramway plant added, and others, like Plymouth, which was the first, designed especially for the combined supply. All kinds of objections were formerly raised against combined stations. Engineers who ran lighting plants were supposed to be unfit to be trusted with the supply to a tramway. Tramway work was said to impose such strains upon the machinery that not only was no lighting plant capable of standing them, but also that American-built engines were absolutely essential. In the light of experience these and other myths have disappeared, until practically the only question now left is the most important of all: "Can a combined station sell electrical energy to a tramway as cheaply as the tramway can produce its own?"

In an appendix to this paper are given several tables in which are set out the prices charged for lighting, power, and tramway supply by the various owners of a number of combined stations. It has been difficult to get at the exact figures in many cases, but it is believed that those given are substantially correct. In some 60 towns the lighting and tramways are owned by the same local authorities, and the prices charged for energy to the tramways departments vary from 2·75d. to 1d, with an average of about 1·62d. per unit. In three cases where the tramways owned by one local authority run into the districts of other local authorities, energy is purchased from the latter at from 2d. to 1d. per unit, and in one case energy is temporarily taken by one local authority from an outside corporation at 1½d. per unit. Twenty-five corporations supply energy to various tramway companies within their areas at prices varying from 2¼d. to 1d. per unit, with an average of about 1·67d. per unit. On comparing any of these figures with the published returns of local authorities owning separate traction stations, one is at once struck by the apparently low cost at which the latter can work. Out of 10 towns the highest cost is given as ·86d. per unit and the lowest ·34d. per unit, with an average of ·515d. per unit. There does not appear to be much room for combined stations after that!

Comparisons, however, are odious, especially when unlike things are compared. The price at which an article can be sold depends upon the entire cost of its production. While the author is bound to acquit those who publish and those who supply the figures for publication of any desire to mislead, yet he must protest against such figures as those just quoted being used to express the "total power costs." They do nothing of the kind. They are merely "works costs," and do not include either rents, rates, and taxes, insurance, or any office expenses. Even the addition of these items would not give "total power costs," and we have to include interest, sinking fund, and depreciation (or reserve fund) charges before the real cost of the unit is obtained. When all these have been added, it will be found that in many instances the so-called "total power costs" have been doubled, and the actual cost of production will have been brought to figures not very different from those at which energy is sold to tramways from a combined station.

To show the absurdity of the whole thing, we only have to ask any of the tramway undertakings generating their own electrical energy, and whose returns are published in the *Electrical Times*, whether they would be prepared to sell energy at the "total power costs" there given, even with the addition of 10 per cent. as a substantial profit. We have an answer to hand from Glasgow, where, although the

* Paper read before the Municipal Tramways Association.

Digitized by Google

so-called "total power costs" are only ·41d. per unit, 1,243,632 units were sold last year to the electricity department at an average price of 1·47d. per unit. There is no doubt that in some cases the price charged for tramway energy is too high, but in others it would appear almost as though it were being sold under the real cost. The extremes are reached at Dover (2·75d.) and Bradford (1d.) It is not fair that the tramways should be called upon to pay a high price merely to balance a loss on the lighting undertaking. Neither is it fair to sell under cost to the tramways because a profit happens to be made on the lighting. Each class of consumer should be treated in the same way, and if a profit be made by the electricity works, each class should contribute to it at an equal rate. It should not be a difficult matter to arrive at a fair basis of charging. Generating electricity for tramways is exactly the same process as generating it for lighting or any other service, and the only difference between the two is that the tramway demand lasts for perhaps 16 hours per day, while the lighting only lasts for an average of about three hours.

Generating costs are of two kinds: (*a*) those which depend only upon the maximum amount of energy demanded; and (*b*) those which depend only upon the number of units generated. The former decide the amount of plant which has to be provided, and therefore, while fixed in actual value for a station of any given size, are lessened per unit in almost direct proportion to the number of units generated. The latter are, practically, a constant value per unit. The one may be called "fixed costs," and the other "running costs." In "fixed costs" we may include interest, sinking fund, and depreciation on land, buildings, and plant; rents, rates, taxes, and insurances; salaries and wages at generating station of the stand-by staff required, whether the output be large or small; coal, water, etc., required for keeping certain boilers under steam in readiness for "peak" load. In "running costs" we may include coal, water, oil, etc., used in running plant under load; salaries and wages of staff other than above; repairs to plant.

To allocate properly to the lighting and tramway departments their correct shares of the above costs, we have to estimate: (1) the maximum demand in kilowatts of each service (from this we know how much plant to provide for each, including spares, and therefore the "fixed costs" for each service); (2) the approximate output in units per annum taken by each (from this we know how to arrive at the "running costs" for each service). This is equivalent to saying that the correct charges for supply from combined lighting and traction stations may be obtained by the use of the "maximum demand" system, but it must be properly applied. In the author's opinion, there should be one electricity supply department for the town, and it should provide all energy required, and for whatever purpose. It should feed into the overhead wires of the tramway department just as into the wiring of any building, and, as a result of this, it should provide all underground feeder and distributing cables. By adopting the "maximum demand" system of charging, all energy would be fairly supplied on the same terms, whether to tramways, to public lighting, or to private users. But the initial price should be kept high and for as short a period as possible, while the second price should be kept as low as it was possible to make it. All classes of consumers would then be charged at rates in accordance with their use of the supply, and the "long-hour" demand of the tramways would result in a very low actual price per unit.

To simplify the book-keeping, the tramway demand and output could be calculated at the beginning of each year, and the average price per unit arrived at. Thus, if 8d. per unit prove to be the correct charge for the first hour's supply per day and ¾d. per unit afterwards, an average 16-hour tramway load would come out something like—

$$\frac{8\text{d.} + (15 \times \tfrac{3}{4}\text{d.})}{16} = \frac{8 + 11{\cdot}25\text{d.}}{16} = \frac{19{\cdot}25\text{d.}}{16} = 1{\cdot}2\text{d. per unit.}$$

It is difficult to give any opinion as to what the figure really ought to be in each case without knowing all the circumstances. Manifestly, where the tramway demand lasts only 10 hours per day, the cost per unit must be higher than where it lasts 16 hours, as the "fixed costs" would be unaltered. And where coal costs only 6s. per ton the unit must cost less to generate than where coal costs 20s.

It is therefore unreasonable and beside the mark for the tramway department of one town to grumble if it be asked to pay 2d. per unit because another town only charges 1·5d, unless all the circumstances are alike. In the author's opinion, however, the price per unit for a 10-hour tramway load per day should not be more than about one-half and for a 16-hour tramway load not more than one-third of the average price per unit for a three-hour lighting supply. If rates higher than these be charged, it will be found, in all probability, that the tramway department is being asked to bear costs which should belong to the lighting department.

* Plus 10 per cent. per annum on capital expended on plant, feeders and overhead.

DISCUSSION.

Mr. W. N. TITTENSOR, of Preston, made a long contribution to the discussion, the gist of which was that the tramway undertaking ought never to be charged more than 1d. per unit in a town where coal was obtainable at 15s. per ton. He defended his charge of 1½d. per unit at Dundee on the grounds that the plant was not an up-to-date one. At Preston the electric light company had offered to supply the tramways for 1⅛d. per unit, but he had advised his committee that they could generate their own current for 0·96d. The balance-sheet for the first year's working had yet to be audited, but it showed a works cost of 0·58d., and a total cost, including capital charges, of less than 0·9d.

Bailie ALEXANDER, of Glasgow, said that the question largely depended on the point of view from which it was approached. Each man was apt to look at the matter from a personal point of view, and not as to what was best for the whole community. He thought that if the town was large enough to warrant the highest class of supervision for each undertaking, there was much to be gained from having two generating stations, between which a certain amount of rivalry and emulation would exist. Where there was one station, he thought there should be one committee and three sub-committees, dealing respectively with the generation of electricity, the supply of light and power, and the running of the tramways. The first committee would then generate and sell electricity to the other two. The figures which were given by the author as to the Glasgow tramway station did not make it clear that the power supplied to the electric lighting department was used on peak load. He thought that this justified the charge of 1½d. per unit, and he considered that the Lighting Committee sold electricity on the peak load at 6d. per unit. The Tramway Committee had recently agreed to supply more electricity to the Lighting Committee at the rate of 1d. per unit.

Treasurer LYON, of Aberdeen, agreed with the last speaker, and considered that in his city they gained from having one first-class plant controlled by a single first-class engineer. Under the arrangement in Aberdeen the tramway department paid for its power exactly what it cost to produce. This last year was certified by the city accountant to be 1·51d., which agreed very closely with Mr. McElroy's figure of 1·49d. for Manchester.

Mr. H. E. BLAIN, of West Ham, chaffed electrical engineers because they covered up their figures of costs under technicalities which were difficult to disprove. His conclusion was that these engineers were making a handsome profit out of the tramway undertakings. He wished Mr. Rider's paper had gone farther and that he had analysed the figures of the cost of supply to tramways from separate stations. He (the speaker) had gone into this, and found that these costs, including capital charges, were as follows: at Glasgow, 0·92d. per unit; at Birkenhead, 1·01d.; at Reading, 1·02d.; at Sheffield, 0·645d.; and at Leicester, 0·498d. Of this latter figure 0·306d. was the works' cost per unit, and the capital charge of 5½ per cent. for interest and sinking fund averaged 0·192d. After some remarks as to errors in metering and to private consumers being charged less for power than tramways, Mr. Blain gave his estimate as to what it would cost to supply the tramways at West Ham from a separate station. This would vary from ·98d. to 1·19d., according to the units used.

Alderman HEY, of Halifax, considered that even if a separate tramway station would give a cheaper supply, the general community might benefit considerably from having the two undertakings on one supply station. In Halifax this had been found to be the case. The starting of the tramways had enabled the lighting department to pay even with a reduction in the charge of energy for lighting from 6d. to 4d. per unit.

Mr. C. J. SPENCER, of Bradford, considered that the price charged to tramway departments from combined stations had been rather a matter of bargaining than of policy. He was surprised that the charge at Manchester was as high as 1·49d., and wondered as to how much of the plant in the station was charged against the tramway department when calculating the depreciation. He queried the position at which metering could be done. If the meters were placed in the station, the tramway department had to pay for all losses in transmission and distribution. He thought the meters should be placed out on the system as they were in the case of lighting consumers.

Mr. P. FISHER, of Dundee, thought that many of the speakers had mistaken Mr. Rider's point, which was—can the supply be given to tramways from combined stations as cheaply as from separate works? Most of the speakers had considered rather the question—is the supply given as cheaply? He thought that the Aberdeen figures of cost were wrong, but believed in combined stations.

The TRAMWAY ENGINEER of BOLTON also questioned the accuracy of electricity meters. Combined stations might be good for the ratepayers, but tramways could be supplied more cheaply from their own works.

Mr. J. H. RIDER, in reply, said he was pleased that such a long and useful discussion had followed a paper which he had prepared at very short notice. He believed not in having a lighting department to supply the tramways, but in having an electricity department which would sell current to all requiring it. The argument that there were two departments at Leeds, and that one was supplying cheaper than the other, could be answered by him to the effect that if the right system of charging were adopted it would be cheaper to have one station. It was true that the London County Council were putting down a traction station, but then they were not the supply authority. If they became so in the future, he would advocate one station for traction, lighting, and power. He was glad to get Mr. McElroy's support, as it was at Manchester that the correct system of charging for electricity supply was first adopted under the advice of the late Dr. John Hopkinson. He formulated the idea of dividing the charges into capital and running expenses, and if only the right division was made, an equitable system was assured. A high first charge for a short period was required, and this, unfortunately, was limited by the maximum in the provisional orders. The first charge should be made as high as possible and for a very short period, after which the bare running expenses should be charged on the rest of the consumption. This second charge should be fixed at the lowest possible value. Care should also be taken that the depreciation charges met by both lighting and traction consumers were fairly distributed.

A hearty vote of thanks was passed to Mr. Rider for his paper.

LANCASTER ACCOUNTS.

The following abstract of the revenue account is taken from the accounts of the Lancaster Corporation electricity department for the year ended March 25, 1905.

Dr. *Expenditure.*	£	s.	d.

APPOINTMENTS VACANT.

Shift-Engineer Foreman. Applications to Box S 92, *Electrical Engineer* Office. See advertisement in previous issue.

Various.—Head of electrical engineering department; salary, £200 per annum. Head of civil and mechanical engineering department; salary, £200 per annum. Assistant for building construction, etc.; salary, £130 per annum. Halifax Education Committee. Applications by July 11. See advertisement in last issue.

Borough Electrical Engineer, Cheltenham. Salary, £400 per annum. Applications by 18th inst. See advertisement.

Lecturer on Electrical Engineering, Hull municipal technical school. Salary, £200 per annum. Applications, on forms, to J. T. Riley, D.Sc., director of studies, by 15th inst. See advertisement.

Electrical Engineer as manager to lighting and power contractors. See advertisement.

Draughtsman for switchgear work, Ferranti Limited, Hollinwood, Lancs. See advertisement.

FORTHCOMING EVENTS.

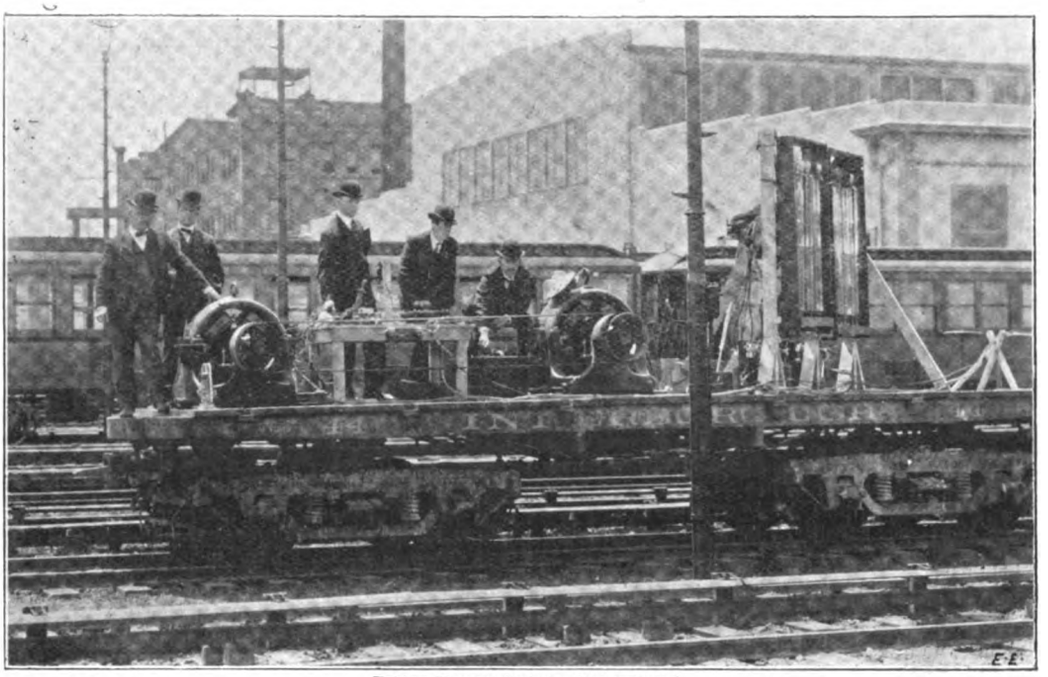
University of Liverpool.—Opening of new electrotechnics laboratory by Sir J. Swan, July 8.

Permanent-Way Institution. — Summer convention begins on July 21, continuing till July 27, in the course of which a visit will be paid to Holland.

Digitized by Google

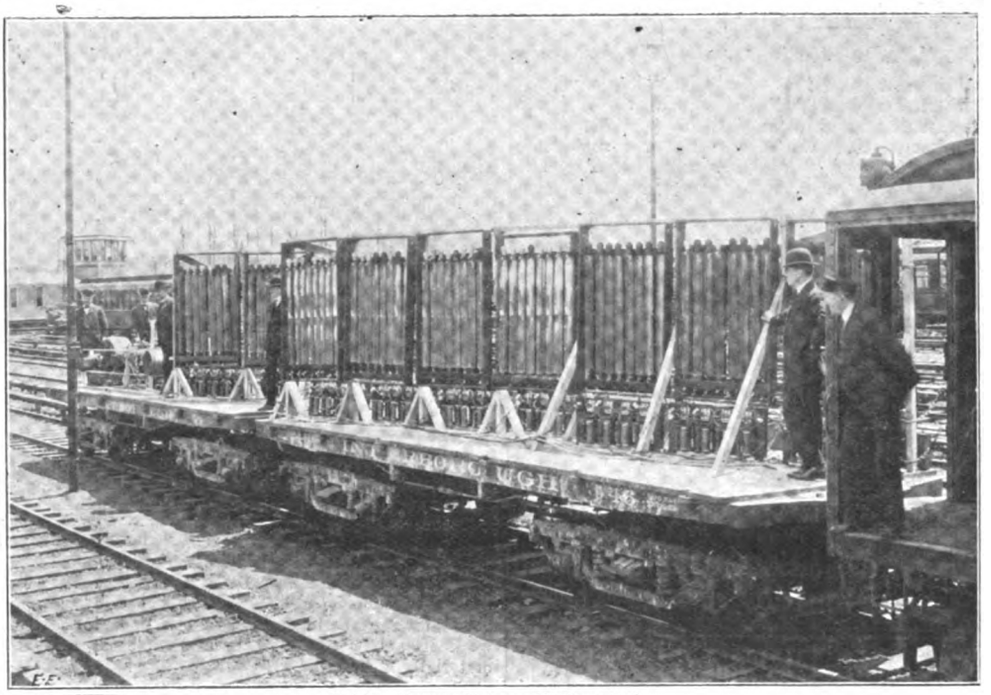
TAKING MOVING PICTURES UNDERGROUND.

A series of interesting moving pictures were taken a short time ago by the American Mutoscope and Biograph Company in a section of the subway of the Interborough Rapid Transit Railroad of New York. A number of scenes were included of the stations when the passengers were leaving or boarding local trains, and the results were in every way successful. The light by which these photographs were taken was provided by a number of the Cooper-Hewitt lamps fixed on two flat cars in nine banks of eight lamps each. The lamp known as the "K" type, which is 45in. long, was used, and the total candle-power of light amounted to 52,500 c.p. The banks of lamps were mounted diagonally across the foremost car, so that the light was thrown immediately in front of the camera, which was mounted on the next car. Each lamp was backed by a polished metal reflector, and the kicking coils by means of which the lamps are started were arranged underneath the frame.



Taking Moving Pictures Underground.

The manner of generating the current is worthy of note. A Westinghouse 40-h.p. 600-volt motor taking its current direct from the third rail was mounted on a truck and connected by belt to a 22½-kw. Westinghouse 110-volt generator. The various auxiliary apparatus, such as voltmeters, rheostats, switches, etc, were conveniently mounted between the two machines. The work was entirely successful, and during the entire trip only one lamp went out. The details of the subway construction were brought out with extraordinary clearness, due to the exceedingly high actinic power of the Cooper-Hewitt lamp The accompanying illustrations show the arrangement of the lamps and the generating outfit on the cars.



Taking Moving Pictures Underground.

ROBERTSON ELECTRIC LAMPS LIMITED—ANNUAL OUTING.

The outing to which the directors of the Robertson Electric Lamp Works at Brook Green annually treat their staff and employés, and incidentally some favoured visitors, has always been, as far as we can assert from personal knowledge, a howling success. This year it took the form of a trip to Margate, leaving Victoria last Saturday at 8 a.m., and no wonder when the hundreds of girls trooped into the station wringing wet the genial manager, Mr. C. Wilson, feared the

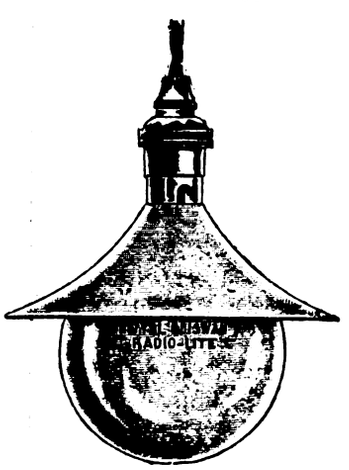
Digitized by Google

day which was beginning. However, all got aboard safely bar those who were unfortunate enough to come by the Underground, which was flooded by that time. They missed their train. Some of them came on by a later train; the others missed a treat. Soon after Sittingbourne the sun came out, and when Margate was reached the beach and town blazed forth in a golden July sun under the bluest of skies. A most enjoyable dip in the ocean at Cliftonville commenced the proceedings, and an excellent dinner followed at 12.30 so as to leave a long afternoon before the party. We may say here that by the party we understand the staff of the works (about 30) and their guests. The firm on these occasions go upon the sensible plan of providing a train, etc., for all their employés, and the husbands and wives of those who are thus blessed, and to leave them to roam at their free will upon arrival at the port selected. The young people, being away from the all-seeing eye of the foreman and staff, enjoy themselves all the better for being left to their own devices. And that is where part of the howling success comes in. Some call it singing, but no matter. There was not much speechmaking at the dinner, but the toasts of the company, the managing director (Mr. C. Wilson), the staff, and the organising secretary (Mr. Saville, who deserves all the praise bestowed upon him, and so forth) were duly honoured. From what we heard, the company is still making rapid progress. This year the output increased by 40 per cent., reaching a total of 4,000,000 lamps. This necessitated a corresponding increase in the number of employés, and considerable extensions to the factory, which have been carried out and completed satisfactorily. We are glad to learn that there was not a single accident during the whole year. After dinner a brake and a landau, the latter of which nearly came to grief in a collision, took the party through the wheat and barley fields to Birchington, and a prolonged halt was made at the Minster Gardens for strawberries, tea, and frolic. We have been asked to specially notice the running form of some elderly gentlemen present; and while on the subject of sport we must mention the excellent shooting in the subsequent match, Messrs. Wilson, Saville, and Hogg coming out with 31 and 29 points respectively. After the return to Margate there was yet another tea, a lovely walk along the front, and a lively return to Victoria, which was reached at midnight without any mishap, and with the unanimous feeling of having been made to have a real good time.

TRADE NOTICES AND NOVELTIES

The "Radio-Lite" Lamp.

Accompanying is an illustration of the "Radio-Lite" lamp, which has been put on the market by the Edison and Swan United Electric Company, Limited, to meet the growing demand for a special form of spherical-shaped electric lamp. It is manufactured in two sizes—viz., Types II. and V.—and for any voltage from 100 to 250. In Type II. the diameter of the bulb is 4in., and in Type V. the diameter of the



bulb is 5in., giving a downward reflection of 40 c.p. to 50 c.p. and 80 c.p. to 90 c.p. respectively. It gives a beautiful soft bright light; on account of the special method of frosting adopted and the position of the filament the diffusion is particularly fine. This lamp will, the company believe, become indispensable for the special purpose it has been designed—viz., shop lighting, corridors, institutions, house lighting, etc.

LEGAL INTELLIGENCE.

LLOYD'S v. THE MARCONI INTERNATIONAL MARINE COMMUNICATION CO.

In the Chancery Division, on Wednesday, Mr. Justice Kekewich heard an adjourned summons in the action of Lloyd's v. Marconi International Marine Communication Co., by the company, against the plaintiffs, asking for further and better affidavit of documents. Mr. Ogden Lawrence, K.C., and Mr. Ashworth Jones (instructed by Messrs. Waltons, Johnson, Bubb, and Whatton) appeared for the plaintiffs, and Mr. Stewart-Smith, K.C., and Mr. Gover (instructed by Mr. Geoffrey Chubb) for the company.

Having heard counsel on both sides, his LORDSHIP said the difficulty was very much increased by what he had no doubt was a perfectly genuine attempt on the part of the plaintiffs to avoid any question of shirking discovery. Still he was afraid they had done themselves harm; but probably in a further affidavit which he was going to direct, the plaintiffs would think it right to recall as far as they could the action up to a point. His Lordship thought it would be proper to order a further affidavit of documents, but with regard to the point made as to the title of Lloyd's to certain signalling stations, it seemed to him that the defendant company was in the wrong. Costs would be costs in the action.

COMPANIES' MEETINGS AND REPORTS.

CHILI TELEPHONE.

The report for the year ended March 31 states that the aggregate number of subscribers at all centres at the end of the year was 6,874, as compared with 5,814 at the beginning, or a gain of 460 for the year. The gross revenue in Chili from all sources was 978,746dol., an increase of 62,204dol. The expenditure in Chili was 445,140dol., an increase of 22,731dol. The net income in Chili from all sources was 533,606dol., an increase of 39,473dol. The average rate of exchange for the year was 16 30d. as compared with 16·36d. in the previous year, giving a decrease for the year of 0·06d. Converted into sterling at these rates, the net income was £36,227, an increase of £2,540. The liquid assets and liabilities in Chili on March 31, 1905, were valued at 16¼d., the current rate of exchange on that day, as compared with 16⅝d., at which they were valued on the corresponding date of the previous year. The balance to credit of the revenue account, including £2,502 brought from the previous year, is £34,547, of which £15,360 has been carried to reserve for renewal of plant, etc. An interim dividend of 3s. per share was paid on Jan. 14 last, and the directors now recommend a final dividend of 5s. per share, leaving a balance of £2,467 to be carried forward. The total mileage on March 31, 1905, was 10,759 miles, an increase of 875 miles.

ELECTRICAL POWER STORAGE.

The report for the year to May 31 states that the profit, including the balance of £470. 17s. brought forward, amounts to £9,600. 14s. 8d. Out of this sum the directors have carried £1,000 to the contingent fund, and set aside £2,500 for depreciation of patents, goodwill, etc. They recommend again the payment of a dividend of 6 per cent. on the ordinary share capital, which will absorb a further £5,389. 13s. 7d. and leave £711. 1s 1d. to be carried forward. In addition to the £2,500 set aside as above, the directors have transferred £13,500 from the special reserve account, making £16,000 in all, which has been applied in reduction of patents, goodwill, etc. This leaves £10,000 at the credit of special reserve to provide for possible diminution in the value of the assets, for repayment of debentures, etc. The buildings, plants, tools, etc., have been maintained in thorough repair and condition at a cost of £3,540. 18s. 4d., which sum has been provided out of revenue. The directors are glad to record another satisfactory year, notwithstanding the continued industrial depression and increased keenness of competition.

BIRMINGHAM AND MIDLAND TRAMWAYS.

The report states that the total revenue for the year, including £695 brought forward from the previous account, amounts to £108,626, and after deducting expenses chargeable to revenue, including repairs and maintenance, there remains £35,948. Deducting interest on the debenture stock and the dividend on the 5½ per cent. preference shares, amounting together to £14,996, there is an available balance of £20,951, which the directors propose should be applied as follows: to payment of a dividend on the preferred ordinary shares at the rate of 5½ per cent. for the year ended Dec. 31, 1904, £19,250; to be carried forward to next account, £1,701. The traffic receipts have suffered during the past year by reason of the dislocation of traffic brought about by the reconstruction of the lines for electric traction. The work has, however, now been completed, and the receipts have materially increased.

ELECTRIC CONSTRUCTION.

The report for the year states that the net profit is £3,908. 14s. 3d., and adding £3,805. 3s. brought from last year, the amount available for distribution is £7,713. 17s. 3d. The directors recommend that this profit be appropriated as follows: dividend at the rate of 7 per cent. per annum on the preference shares (to be paid on July 31 next), £4,394. 12s.; balance carried forward to next account, £3,319. 5s. 3d. The buildings and plant have, as formerly, been thoroughly maintained out of revenue, and £5,000 has been credited to depreciation account. The depreciation account now amounts to £58,000 and the general reserve fund to £32,000. The competition referred to in last report has been intensified during the year and still continues, but there are signs of improved trade in the near future. Meanwhile, every effort is being made to meet by economy and improved administration the low prices now current.

Digitized by Google

GREENWOOD AND BATLEY.

At the annual meeting of this Company last week, the CHAIRMAN stated that the net profits for the year amounted to £32,000, representing an increase over the previous year of £6,000. A number of large orders were completed during the latter half of the year. A sum of £5,000 has been added to reserve, bringing the amount up to £55,000. The Company's plant now includes a 800-h.p. de Laval turbine, which has been found to result in an economy of fully £1,500 per annum. In conclusion, the chairman stated that the prospects for the ensuing year were encouraging, and the motion adopting the report and declaring a dividend of 7 per cent. on the preference shares and 6 per cent. on the ordinary shares was carried unanimously.

UNITED RIVER PLATE TELEPHONE.

The ordinary general meeting of this Company was held on Tuesday at Winchester House, Mr. J. I. Courtenay presiding. Particulars of the report appeared in our last week's issue.

The CHAIRMAN, in moving the adoption of the report, stated that the progress of the Company during the year was shown by the increase in the number of subscribers in the Buenos Ayres section, which was considerably in excess of that of any previous year. The directors were able to recommend a final dividend of 5 per cent. on the ordinary share capital, making, with the interim dividend, a return of 8 per cent. for the year. They intended to make an immediate issue of £50,000 in ordinary shares, which will be offered to the ordinary shareholders at par, to provide for the various requirements in connection with the continued extension and growth of the Company's business. The directors were adopting the policy of making moderate issues so as to avoid as far as possible calling up capital not immediately required in the business.

The report was adopted.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Leicester.—Tenders are required for telephone cables, etc., for the Water Committee. Tenders by July 17.

Bath.—The Corporation invite tenders for a storage battery. Tenders by July 17. See advertisement.

Turnu-Severin (Roumania).—The Mayor invites tenders for the electric lighting of the town. Tenders by Sept. 10.

Fulham.—The Council invite tenders for extension of cables, feeders, etc. Tenders by noon on July 12. See advertisement in last issue.

West Ham.—The Council invite tenders for the erection of tramway offices and car depot, Greengate-street, Plaistow. Tenders by July 25.

Ilford.—The Urban District Council invite tenders for the supply of ·4in. and ·25in. concentric cable. Tenders by 4 p.m. on July 11. See advertisement.

South Shields.—The Town Council invite tenders for the laying of the permanent way for the service line to the car-shed in Dean-road. Tenders by 22nd inst.

London.—The London County Council invite tenders for two low-tension feeder switchboards. Tenders by 10 a.m. on July 11. See advertisement in last issue.

Leeds.—Tenders are invited for the supply of lamp-pillars, irons, carriages and furniture, and glass for lamps for one year, for the Street-Lighting Committee. Tenders by July 18.

Paris.—The Postal and Telegraph Department, No. 103, Rue de Grenelle, require tenders for copper wire cased in indiarubber and cotton and dipped in paraffin. Tenders by 3 p.m. on July 12.

Burton-upon-Trent.—The Corporation invite tenders for the electrical equipment on the overhead system of about 1¾ miles of tramway (Contract No. 10). Tenders by noon on July 7. See advertisement in previous issue.

Alicante (Spain).—The Harbour Board (Junta des Obras del Puerto) require tenders for two electric cranes, capable of lifting 10 000 ko. and 1,500 ko. respectively. Tenders by Sept. 15. Estimate, 107,010·10 pesetas.

Loughborough.—Tenders are invited for the supply of materials and stores for the year ending July 31, 1906, for the electricity works. Tenders to the Borough Electrical Engineer by July 18. See advertisement in last issue.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

Merthyr Tydfil.—Tenders are invited by the Urban District Council for the erection of refuse destructor plant capable of effectually burning 120 tons of refuse per day, together with all buildings and contingent works connected therewith. Tenders by Sept. 1.

Neath.—The Rural District Council invite tenders for the supply, etc., of electric light and power mains, sub-stations, switchboards, feeding pillars, switch pillars excavations, and other works in connection within their area. Tenders by July 17. See advertisement.

London, S.W.—The London County Council invite tenders for the roadwork and plate-laying required for the construction for electrical traction on the conduit system of the authorised tramways from Wandsworth to Tooting via Red Lion-street, South-street, Garratt-lane, and Defoe-road. Tenders by 11th inst.

Wishaw.—Tenders are required for (1) underground mains; (2) excavation, temporary and permanent reinstating; (3) street arc lamps. Particulars can be obtained from the engineer, Mr. E. F. Cox, 10, Russell-street, Wishaw, N.B., on payment of a deposit of £2. 2s. Tenders to Mr. J. Logan, town clerk, Main-street, Wishaw, N.B., by 12 noon on July 11.

Stourbridge.—Tenders are required for the wiring of the workhouse buildings for electric light, also for the installation of a plant for working the same; also for the installation of gas pipes and fittings, according to specification which can be seen at the Clerk's Office. Tenders to Mr. George Francis James, clerk to the Guardians, 12, Hagley-road, Stourbridge, by 12 noon on July 12.

London, S.W.—The London County Council invite tenders for the roadwork and plate-laying required for the reconstruction for electrical traction on the conduit system of the tramways (*a*) from the authorised tramways in Red Lion-street, via York road, Battersea Park-road, Nine Elms-lane, Albert-embankment and Lambeth Palace-road to Westminster; (*b*) along Lambeth-road; and (*c*) along Falcon-road; and for the execution of certain paving works in connection therewith. Tenders by 18th inst.

Erdington.—Tenders are required for the construction of Section No. 1 of the Erdington tramways, comprising the laying of the permanent way, including copper bonding, wood block paving, and other works incidental to the laying of about 2½ miles of double-track tramway, for the Tramway Committee. Tenders to the joint engineers, Mr. Robert Green (of Messrs. Pritchard, Green, and Co.), of 37, Waterloo-street, Birmingham, and Mr. Herbert H. Humphries, engineer to the Council, Public Hall, Erdington.

RESULTS OF TENDERS.

Canterbury.—The tender of C. Breeze, Canterbury, at 13s. 6d. per ton, has been accepted for supply of coal to the electricity works, for the Town Council.

Gravesend.—The tender of S. Blandford, Gravesend, at £51, has been accepted for installation of electric light at Church-street School, for the Education Committee.

Aston.—The Public Works Committee have recommended for acceptance the tender of the Brush Electrical Engineering Co., at £4,505 15s. 7d., for the overhead electrical equipment of the tramways in High-street, Birchfield-road, Lozells-road, Witton-road, and Wheeler-street.

Cables, etc.—The Johnson and Phillips Electric Cable Works, Ol Charlton, report the following contracts: Ipswich, distributor mains Grimsby, distributor mains; Great Northern Railway Co., feeder and distributor mains; Handsworth, additional lighting and tramway feeder and distributor mains for the Witton district; Pembroke Dockyard, additional lighting and power feeders.

Norton.—The following tenders for the laying of the main from Wold-road to Whitewall have been received:

J. Taylor, Malton	£139 10 0
E. Leefe, Norton	148 18 0
R. Yates and Sons, Malton	118 10 0
J. Read, Malton	132 12 10

Marylebone.—Tenders were received from 46 firms for the supply of stores to the generating station. The following firms have been selected: G. Hatch Limited, white cotton waste, £1. 13s. 6d. per cwt., common 18s 6d.; W. H. Wilcox and Co., mutton cloths £1. 18s. per cwt., sponge cloths 10s., lubricant for grease lubricators 3d. per lb., asbestos packing 1s. 2d., rubber insertion 1s. 6d.; British Insulated and Helsby Cables, cables of various sizes and prices; Baxter and Counter, cable-jointing materials—viz., Para rubber strip, black adhesive tape, binding wire and fuse wires, indiarubber solution, shellac varnish; Veritys Limited, indiarubber gloves; St. Helens Cable Co., prepared tubing.

New Ferry (Cheshire).—The Lower Bebington Urban District Council have received the following tenders for the work of electric installation for fire brigade alarm in New Ferry:—

Barlow and Young	£65 10 0
Electrical Engineering and Maintenance Co.	49 0 0
Pulford Bros.	48 11 8
Price and Taylor	40 15 0
H. G. Ruddell	34 2 6
Cox-Walker and Co.	33 0 0
Frith and Son	27 0 0
National Telephone Co.	26 17 10
Lloyd and Co., King-street, Rock Ferry (accepted)	25 0 0

BUSINESS NOTES.

TRACTION.

Southampton.—The Town Council have decided to introduce single-deck cars.

Radcliffe.—The Dumer's-lane section of the Urban District Council's system has been opened.

Cape Electric Tramways.—An interim dividend of 2½ per cent. has been declared by the directors.

Southowram Light Railway.—An enquiry has been held into an application for extension of time to construct this line.

Keighley.—It has been decided to apply to the Board of Trade for an extension of time in which to complete the Stockbridge section.

Llandilo.—An enquiry is to be held on the 14th inst. by the Light Railway Commissioners as to the expediency of granting an order for a light railway.

Halifax.—The Corporation have replied to the Zoyland District Council that at present they are not prepared to extend the tramways to Ripponden.

Digitized by Google

Portmadoc and South Snowdon.—The Light Railway Commissioners have submitted to the Board of Trade for confirmation an order sanctioning this line.

Liverpool-Southport.—Through bookings have been instituted between the Liverpool Overhead Railway and the electrical section of the Lancs. and Yorks Railway.

Baker-street and Waterloo Railway.—A Select Committee of the House of Lords has passed the Bill authorising a subway at Charing Cross for foot passengers.

Brighton.—The Corporation "tourist car," inaugurated at the instance of Mr. Marsh, the acting engineer and manager, made a trip on Monday, and was well patronised.

Rowley Regis.—It is proposed to hold a conference between the Urban District Council and the Birmingham and Midland Tramway Co. in reference to the tramway to Blackheath.

Bishop Auckland.—The United Kingdom Tramway, Light Railway, and Electrical Syndicate have applied to the Board of Trade for an extension of time in which to construct the Bishop Auckland, Shildon, and Spennymoor tramways.

Lincolnshire Light Railways.—In regard to the two light railway schemes for this district, it is reported that the promoters of the Barton Railway have withdrawn their scheme, so that there will only be the Lindsey scheme for the Commissioners to enquire into.

Blagdon and Pensford Light Railway.—A committee has been appointed, by the Somerset County Council, with power to assent to the construction of this light railway, on being satisfied that all the reasonable requirements of the county surveyor were complied with.

Yarmouth.—The electrified line from Yarmouth to Gorleston was opened on Tuesday. This is expected to form an important and remunerative section of the Yarmouth system already in operation on the other side of the river, with which it is hoped shortly to be linked up. The inaugural ceremony was followed by a luncheon, at which several members of the Corporation, officials, and others were present. The cost of the new section was £50,000.

Barry.—The Urban District Council have under consideration a scheme to provide the town with a system of electric tramways. The service will supply not only the town, but will also extend to the island. During the past week or two a census has been taken on behalf of the Council of those using the brake service and the foot passengers between the town and island, and the results are such as to encourage the local authority to proceed with their scheme.

Fareham.—The Gosport and Fareham Tramway Co. sought permission from the South-Western Railway Co. to continue the laying of their lines as far as the railway station, thus passing over some 80 yards of the company's private road. In reply, the railway company state they will only allow the metals to be laid to within 100 yards of their property. It is suggested that a further communication be sent to the company requesting as a compromise that the distance be reduced to 50 yards.

St. Annes.—At the meeting of the Urban District Council a letter was read from the Blackpool, St. Annes, and Lytham Tramways Co. as to the greasiness of the tramlines caused by the laying of Westrumite on the roads. It was resolved that the surveyor be instructed to point out to the tramways company that, inasmuch as the greasiness arising from this cause lasts only a few hours after each application, and as the roads are treated with this solution on four or five occasions only during the year, the matter complained of will not seriously affect the running of the cars.

Balsall Heath.—The Balsall Heath section of the tramway between Birmingham and Mary-street was closed on Saturday morning. As a result of the excavations which have been going on for some time in Longmore-street, where the sewers are being relaid, coupled with the heavy rains, the roadway became undermined. As not only the old track but the temporary track was seen to be unsafe, this section was closed. The contractor had a gang of men hard at work laying a temporary track on a part of the roadway which was considered safe, and towards two o'clock the route was again reopened for traffic.

Bath.—At the meeting of the Rural District Council a report was presented with reference to the Weston-to-Lansdown Light Railway. The present width of High-street is not sufficient to permit of a tramway being laid along it to connect the present tramway system with the line up to Lansdown, but the committee saw no objection to the scheme if the promoters were willing to undertake the widening of the road. That would mean the securing of half a dozen cottage properties not very valuable. If that were done, it would be a great improvement. It was imperative, however, that High-street should be widened before trams went there. The report was adopted.

Barcelona.—The Barcelona Tramways Co. announce that a contract has been entered into for the sale of the undertaking at a price which, including accrued profits to June 30 last, will permit, after paying off the debentures, debenture stock, and preference shares with interest, of a return to the ordinary shareholders of approximately £14 per share. A first instalment of £5,000 has been paid to the company, and a banker's guarantee for securing payment of the remainder of the purchase money has been arranged to the satisfaction of the Board. An extraordinary general meeting of the company will be called in the course of a few days to submit the agreement for approval.

Dover.—The work on the tramway extension has been delayed by drainage and other difficulties arising from the congested traffic on Crabble Hill. The double line is now laid up to "The Gate," and part of the way the cementing and wood paving has been put down between the rails. From the railway arch on Crabble Hill down to Crabble Paper Mills nothing has been done except the erection of posts to carry the overhead wires. From the mill up to the further side of the athletic ground the rails are down ready for the cement and pitchers. This length has been rather tedious, owing to the elaborate curving of the rails. Beyond the athletic ground the sleepers are down and the rails upon them, but not yet completely laid.

Stretford.—It was reported at the meeting of the District Council that the Light Railway Commissioners had reconsidered the West Manchester light railways order as to a proposal from the promoters to abandon or transfer a part of the scheme. The Commissioners decided they could not report to the Board of Trade in favour of any alteration in the terms of the order. "If any alteration is desired," the Commissioners continued, "it must be made by agreement." As to this they only said that in fixing £1,500 to be paid by the company they had in mind the fact that the earnings on the line in Trafford Park would belong to the company. If the line was owned by the Council some reduction should be made, but the company could hardly expect to escape the payment of a considerable contribution having regard to the fact that they resisted the proposals of the Council.

Maidstone.—At the monthly meeting of the Urban District Council last week it was stated that the net profits on the first 8½ months' working amount to £1,531. 5s. 10d. If the Council succeed in getting an order for taking the line up Week-street and Stone-street, the working expenses will work out more favourably. The profit mentioned has been achieved in the face of a charge of 2d. per unit for power. The Chairman of the Tramways Committee, in concluding his remarks, expressed the belief that the undertaking would be a great success, and would always yield 5 per cent. clear profit, after all expenses had been paid, including repayment of principal and interest. He congratulated Mr. Headley, the electrical engineer, upon the result, and the committee's report was unanimously adopted. An enquiry into the application for sanction to the extension of routes has been opened.

Leith.—The work of laying the new tramway rails and the causeway at the foot of Leith-walk was completed last week, and the completion of the remaining street work in Leith-walk is now a matter of days. The work of fitting up the overhead equipment is not so far advanced, but there is now practically no doubt that the Town Council will be able to carry out their intention to open a section of the new electric system before the trades' holiday at the end of July. Some delay was feared in connection with the overhead equipment, but the Tramways Committee have had an interview with the contractors, and they learn that that equipment will be delivered almost immediately. Ten cars are ready for delivery, and these will, it is expected, be put on the route from the foot of Leith-walk to Newhaven, by way of Pilrig-street, towards the end of this month. It is expected, however, that the formal opening ceremony will not take place until September.

Waltham Abbey.—A committee of the House of Commons last week commenced an enquiry into the scheme for an electric railway from Gracechurch-street to Waltham Abbey. The cost of construction is estimated at £275,862 per mile. The Great Eastern Railway and the London County Council are opposing the Bill, the latter contending that a scale of fares for workmen should be allowed which the promoters say would render the scheme impracticable, though they are prepared to carry workmen at the rate of 3d. return between the City and Walthamstow up to 7 30 a.m. Sir Douglas Fox, chief engineer of the scheme, gave evidence as to its practicability. Sir A. Binnie gave evidence that the project better satisfied the public needs of the district than any other scheme that had been advanced. The commercial side was dealt with by several well-known financiers, who expressed favourable opinions. Mr. Stephen Sellon favoured "zone" fares, and estimated that 44 525,000 passengers a year would be carried between the City and Waltham Abbey.

Derby.—During the past 12 months the receipts from horse traction amounted to £16,297. 18s. 6d., and from electric traction £17,799. 15s. 7d. The sum of £507. 12s. 10d. was received from advertising, making a total of £18,307. 8s. 5d. from the electric cars, and the net revenue amounted to £7,620. 1s. 4d. The repayment of loans and interest absorbed £4,899. 7s. 1d., leaving a net profit for the year of £2 720. 14s. 3d. That spoke very well for the future of their cars. The number of miles run by the electric cars was 411,823½, and the cost of current per car mile was 1 55d. The receipts per car mile came to 10·31d., and the cost of working per car mile was 6 31d. The number of passengers carried on the electric cars was 4,001,009. The Tramway Committee look for much better figures during the ensuing year. The receipts for the last quarter had been £8 069, or nearly a half of the whole they had taken since the cars had been running. The cars have earned £8,000 in the last three months, and in view of the fact that the Kedleston-road route will be open in about three weeks, and that it will have a good portion of the summer traffic, a substantial profit is anticipated. The Corporation unanimously adopted the report.

London County Council.—At Tuesday's meeting the annual accounts were presented, of which we have already given some particulars. The receipts for the electrical section were £545,295, and on the horse section £133 799. The surplus on the working of the electrical section was £182,798 but as there was a small deficiency on the horse section the surplus on the whole is slightly reduced. The total receipts have been £145,856 more than in the previous year, despite the fact that the Streatham service was suspended during electrification. The passengers numbered 164 818,550 being an increase of 31,679,475, and the car miles aggregated 14,081,397, an increase of 2,544 853. The average fare per passenger was ·97d., against ·93d. in the previous year. During the year 81 top-covered cars were introduced, and the earnings were found to be considerably increased. The profits to the Council from the northern section amounted to £53,845. The Islington Borough Council have assented to the use of the overhead system for the Archway-road section. The Highways Committee recommended a vote of £12,500 for a site for a car-shed at

Digitized by Google

Poplar. A recommendation was also submitted that £13,500 be voted for more top covers, and that £19,000 be voted for track work on the conduit principle for the Aldwych subway, the work to be carried out by the Council's staff.

Cardiff.—The receipts of the Corporation trams for last week created a local record, amounting to £2,905. 2s. Considerable inconvenience was caused on Saturday morning to workmen and others proceeding to their work in the early hours, owing to a breakdown in the tramway system. It was discovered about half-past five that a leakage had occurred somewhere in one of the small cables feeding the trolley wire, and it took rather a long time to discover where it was. Eventually a fray was found in one of the small feeder cables connecting one of the underground feeders with the trolley wire, and situate at a place where it could not be easily seen. No time was lost in putting things to rights, with the result that by half-past seven the trams were running, and the many workmen who had been inconvenienced and delayed, and who sheltered from the heavy rain under railway bridges and such like places, were able to proceed to their destinations. In the course of a short conversation, Mr. Arthur E. Ellis, borough electrical engineer and tramway manager, stated to a local reporter that, though the occurrence was annoying, everything had been done to guard against such defects. "When you have between 60 and 70 miles of trolley wire to superintend," he said, "you cannot be looking at every spot at the same moment. This is just the thing which would be caused by weather such as we experienced last night, and it was just the sort of night when our gangs could not work. It was impossible to work in such weather."

Ackworth.—The Light Railway Commissioners have held an enquiry into the proposal to construct a light railway from Ackworth to Shaftholme Junction, near Doncaster, which is really the Yorkshire survival of the Ackworth to Immingham light railway scheme, thrown out last year. The scheme in its present form is in two portions, one relating to the West Riding, and the other for a line in North Lincolnshire from Winteringham to Barton-on-Humber. The Commissioners on this occasion dealt only with the West Riding portion. This proposal is for a single line from a junction with the Knottingley and Swinton Railway at Ackworth. It proceeds in a south-easterly direction through Thorpe Audlin to Kirk Smeaton, where it crosses the Hull and Barnsley Railway, with which a junction is proposed to be given, and thence it proceeds in a south-easterly direction through Norton Campsall, Askern, Sutton, Owston, and Thorpe-in-Balne to Shaftholme Junction on the Great Central and Great Northern Joint West Riding Railway, and also with the Lancashire and Yorkshire. At the other end of the system junctions will be given with the Midland and North-Eastern Joint Knottingley and Swinton Railway. A large number of local authorities, railway companies, and private interests were represented. It is proposed to work the line electrically. The initial outlay is estimated at £12,000 per mile, and the promoters (Messrs. R. E. C. Shann, W. F. Tempest, and others) expect a revenue of about £7,000 per annum. The system will be chiefly used for coal and other goods traffic, but passengers will also be carried. After hearing counsel for the freeholders, the Commissioners intimated that they would communicate their decision in due course.

LIGHTING AND GENERAL.

Hessle.—The Hessle electric lighting provisional order has been confirmed.

Kettering.—The Urban District Council are borrowing £14,500 for electric lighting.

Wallsend.—The electric company have been asked to give a price for the efficient lighting of new streets.

Frome.—The Urban District Council have decided to borrow another £11,000 for the purposes of the electrical works.

Maidenhead.—The Electric Light Committee recommend the adoption of the maximum demand system from Michaelmas.

Beckenham.—Permission has been received from the Board of Trade to an overhead wire to supply electricity to Oak Lodge.

Manchester.—The price of current for electric lighting purposes is to be reduced from 5½d. to 4½d. per unit as and from Sept. 29 next.

Leek.—The question of new plant was discussed at the last meeting of the Electricity Committee and deferred for further consideration.

Trowbridge.—The cable-laying for the proposed electric lighting will be commenced very shortly and will be pushed forward without delay.

Chester.—The Town Council have decided to purchase an additional feed-water pump at a cost of about £100 for the electricity station.

Durham Districts Electric Lighting Provisional Order.—The Bill embodying this order has passed a Select Committee of the House of Lords.

Cardiff.—The Electrical and Lighting Committee of the Corporation last week inspected the Canton electric power station and the Docks sub-station.

Electrical Power Storage Co.—The directors recommend the payment of a dividend of 6 per cent. on the ordinary share capital for year ended May 31, 1905.

Dundee.—The Harbour Trustees have under consideration a proposal to light the Craig Pier by electricity, and have instructed the engineer to report on the subject.

Thetford.—The Urban District Council have assented to an application from the Postmaster-General for the placing of overhead telephonic lines in various parts of the town.

Tredegar.—Expert advice is to be called upon the steps required to be taken by the Council to carry out their obligations under their provisional electric lighting order of 1901.

Hebden Bridge.—The electricity department last year made a gross profit of £37. There is, however, after charges for interest and repayment of loan have been met, a deficit of £459.

Musselburgh.—The employés of the company seem to have scored in the matter of wages, time and a half for Sundays having been conceded them after the commencement of a strike.

Woolwich.—Application is to made for a further loan of £16,275, being the amount spent for mains, switchboard apparatus and instruments, and brick culvert and easement for same.

Dorking.—An enquiry has been held into the Urban District Council's application for sanction to borrow £12,000 for electric light works. A new feeder is to be laid at once at a cost of £680.

Redditch.—The Electric Supply Committee's last report contains the accounts for the 15 months to March last, and show a gross profit of £783, as compared with £460 for the previous 12 months.

Ripon.—A circular has been issued to the inhabitants of Ripon whose rateable value is over £15, asking them to return a signed paper stating whether they would be consumers of electricity if it was installed.

Tunbridge Wells.—On Wednesday a motion affirming that it is desirable in the interests of the general body of ratepayers to consider the advisability of selling the electric lighting undertaking was proposed, and adjourned for three months.

Bridgend.—The District Council are renewing an agreement with the South Wales Power Distribution Co., by which they take all their electric energy from the company, and the company pay the Council 2½ per cent. on the amount of current consumed for lighting.

Birstall.—The Council have decided to purchase current in bulk from the Yorkshire Electric Power Co. under an agreement for 15 years, and it is said at a very favourable price. Application is to be made for a loan of £2,000 for works in connection with distribution.

Alloa.—The Town Council have arranged with the British Electric Plant Co. for the town's electric supply, and have resolved to discontinue the arc lamps in the streets, and to revert to incandescent lamps. It is stated that a saving of £168 might thus be effected.

West Hartlepool.—Terms have been arranged for the supply of electrical current to the Seaton Carew Ironworks for power purposes. This will involve an outlay of nearly £4,000 for a new main, but the net annual return to the Corporation will be from £1,200 to £1,500.

Bishop Auckland.—An application of the Durham Electrical Power Distribution Co. to transfer the Bishop Auckland order to the Cleveland and Durham County Electrical Supply Co., who have a station at Fylands, has received the consent of the Urban District Council.

London County Council.—On Tuesday it was agreed to lend the Islington Borough Council £15,304 for electric light installation and meters and the Stoke Newington Borough Council £900 for site of electricity station. Sanction was also given to the borrowing by the Islington Borough Council of £4,885 for electric light installation.

New Company.—The Bombay Electric Supply and Tramways Co. Limited, has been registered with a capital of £1 200 000, the object being to adopt an agreement with the British Electric Traction Co. for the transfer to this company of the existing tramways in Bombay and of the freehold and leasehold property of the Bombay Tramways Co.

Kendal.—The report of the electricity department for last year shows a deficiency of £821. The whole receipts for electric light have been £905, and the expenditure £725, leaving a gross profit of £180, as against £13 in the previous year. After providing for interest and sinking fund, there was a debit balance of £821 to be carried to the district account.

Norton.—At the last Urban District Council meeting it was resolved that the attention of the Northern Counties Electricity Supply Co. be called to the agreement entered into with the Council, whereby the company undertook to establish works within a period of two years, and that the company be also asked to give the reason why the undertaking was not carried out.

Paris-Rome Telephones.—It is anticipated that direct telephonic communication between the French capital and Rome will be open to the public within three months. An experimental wire of exceptional thickness is now being laid between Rome and Modena, and negotiations are in progress for the carrying forward of the wire by the French Government from Modena to Lyons.

Halifax.—It is proposed that the Education Committee be empowered to appoint on the staff of the municipal technical school one head of the electrical engineering department at a salary of £200, one head of the civil and mechanical engineering department at a salary of £200, and an assistant in the civil and mechanical engineering department at a salary of £130 per annum.

South Metropolitan Electric Light and Power Co.—We are informed that allotment letters in respect of debenture stock, and also of the ordinary and preference shares, offered for subscription on the terms of a circular dated June 23, 1905, have been posted, and the ordinary and preference shares were very largely oversubscribed by the existing share and debenture stock holders.

Fenton.—With respect to a letter from the Board of Trade asking what steps the Council had taken towards carrying out the obligations under the Fenton Electric Lighting Order, 1899, it has been decided to reply that the Council, after due consideration of the matter, have come to the conclusion that the demand for electricity in the district did not warrant the expenditure of providing works and mains.

Digitized by Google

Harrow.—On June 30 the King visited Harrow in connection with the annual speech day, and the considerable extension to the play fields of the school. The town of Harrow decided in consequence of this event to specially decorate the streets and to illuminate them. For this latter purpose the Union "Excello" flame arc lamps have been used, a form of illumination which has proved exceedingly satisfactory.

Swansea.—In accordance with the order of Justice Buckley, the National Telephone Co. are joining up the Morriston and Mumbles and Swansea exchanges. Plans and specifications from the company for joining their lines to the municipal for intercommunication purposes have been laid before the Council. Mr. Mackie is to superintend the work, the services of Mr. Bennett, consulting engineer, being dispensed with.

Parliament.—The following Bills have been read a third time (*a*) in the House of Lords: The Metropolitan Electric Supply Co. (Acton District), South Wales Electric Power Distribution Co., Central Electric Supply, County of London Electric Supply Co., London United Tramways (extension of time); (*b*) in the House of Commons: Dublin United Tramways Bill, Metropolitan Electric Tramways Bill.

Oxford.—The following electric lighting work is to be carried out during the long vacation at Oxford under the supervision of Mr. Morgan Williams, M.I.C.E., consulting engineer to the University: Indian Institute and the University Museum (contractors, Messrs. Hill, Upton, and Co.); the Bodleian Library, camera (contractors, Messrs. W. A. S. Benson and Co.); new examination schools, extensions (contractors, Messrs. Lucy and Co.).

Stock Exchange.—The Stock Exchange Committee have ordered the undermentioned securities to be quoted in the official list: British Electric Traction Co.'s further issue of £415,422 5 per cent. perpetual debenture stock and £160,178 4½ per cent. second debenture stock; Eastern Extension, Australia, and China Telegraph Co.'s further issue of £150,000 4 per cent. mortgage debenture stock (perpetual); Potteries Electric Traction Co.'s further issue of £25,000 4½ per cent. debenture stock.

Surbiton.—The Council have obtained a provisional order to extend the limits of supply for electricity for all public and private purposes to that part of the urban district of Surbiton not included in the area of supply as defined by the Surbiton Electric Lighting Order, 1891, with the insertion of the Northumberland clause. The main object for obtaining an extension of the order was to prevent any other company or firm supplying the added district with electricity.

Scotch Orders.—Sir James Woodhouse's Select Committee of the House of Commons have passed the Rutherglen electric lighting order by altering Clause 7 and substituting the Clyde Valley Electric Power Co. for the Corporation of Glasgow as the body to which the order could be transferred at all. The committee also confirmed provisional orders under the Electric Lighting Acts made by the Board of Trade relating to Denny and Dunipace, Grangemouth, Inverness, Pollokshaws, Renfrew, and Uphall.

Norwich.—The Town Council have agreed to put by the profits made by the electricity undertaking until a substantial reserve has been accumulated. We understand that there is about £6,000 in hand. The business has been increased without any extra expense. Though over a quarter of a million more units than the previous year were generated, the cost of coal has been less. The great increase has been in current supplied for motor power, amounting to 22 per cent., and the lighting has shown an increase of 10 per cent.

Aston.—The Electricity Committee's last report shows that the number of lamps (8-c.p. equivalent) applied for is now 23,857 (not including approximately 400 8 c.p. equivalent at Electric and Ordnance Co.); number of lamps (8 c.p. equivalent) connected, 22,321; horse-power of motors applied for, 576·5; horse-power of motors connected, 518; number of disconnections, 15. The total Board of Trade units metered on consumers' lighting meters during month of May was 15,332; ditto, power meters, 19,880; ditto, traction meters, 72,060; total Board of Trade units sold during month of May, 107,272.

Derby.—An enquiry has been held into an application of the Corporation for sanction to borrow £9,960 for electricity works and lighting purposes for the Duffield-road and Kedleston-road section of the electric tramways. The town clerk, Mr. G. T. Lee, said that £9,600 was required for the extension of the electricity works for the year ending March 31, 1906, and £360 for capital expenditure in connection with lighting. The tramway extension necessitated additional generating power. Part of the route was now lighted by incandescent electric lamps, and it was proposed to utilise the tramway poles for the hanging of arc lamps.

Partnership.—We are informed by Mr. Morgan Williams, M.I.C.E., M.A., that, in view of the extension of his consulting practice, he has taken into partnership Mr. Harold W. Couzens, M.I.E.E., and the business of the firm will henceforward be carried out under the title of Morgan Williams and Couzens at 39, Victoria-street, Westminster. Mr. Couzens, in addition to his extensive experience of electricity supply working, both with municipalities and companies, has for several years past been engaged in the design and supervision of electric power, traction, and lighting undertakings on behalf of Messrs. Kincaid, Waller, Manville, and Dawson.

Torquay.—A letter from the Local Government Board, referring to the application of the Town Council for sanction to borrow £42,000 for the proposed new electric light and power station, has been referred to the Electric Lighting Committee. The Board adheres to the view that the proposals of the Town Council would probably involve a serious loss to the borough. The Board state that they realised the difficulty in which the Council was placed in consequence of the agreement entered into with the Dolter Electric Traction Co., and they suggest that the Town Council should place itself in communication with the Dolter Co. with a view to some arrangement being made.

Pumping.—At the monthly meeting of the South Staffordshire Mines Drainage Commissioners on Wednesday, Mr. E. B. Marten, surface engineer, reported that the wind, steam, and electric surface pumps have worked satisfactorily, and one more wind pump and one electric pump are being arranged for at Portobello. Some useful canal tests have been carried out. Mr. E. Howl, general manager, reported that underground pumps in Tipton district have been raising 8,550,000 gallons in 24 hours, as compared with 7,659,000 last month, and 11,296,000 during the corresponding month of last year. The increase was due to the installation at Park-lane of a new engine driven by Mond gas.

Agencies.—The Northern Electrical and Ventilating Co., of 6A, Stanley-street, Liverpool, have been appointed agents for the Richmond-Carey patent system of push-button lifts (no attendant required), also for their hydraulic, electric, and steam lifts and cranes. Messrs. Johnson and Phillips, of Charlton, Kent, have appointed Messrs. Guthrie Bros. and Ogilvy, of Prudential-buildings, Newcastle-on-Tyne, their sole representatives for the counties of Northumberland, Durham, Cumberland, and Westmoreland, with a view to giving increased attention to their business in that district, and any enquiries for electrical plant of all descriptions sent to the latter gentlemen will receive immediate and careful attention.

St. Annes.—Mr. J. H. Clothier, the electrical engineer, in his last monthly statement, gives the following figures: units sold during May, 35,271; units sold to May 31, 75,996; equivalent to 8 c.p. lamps connected, 17,699; units sold per 8 c.p. lamp connected, 1·65; maximum load—lighting 153·9 kw., traction 132·5 kw.; total number of consumers, 339. They had in addition received since the end of the month five applications for the equivalent of 374 8-c.p. lamps. The increase in units sold for lighting and power was still maintained. The traction output was still less, but last year's returns included the Whit-week traffic. This year's Whit week output showed a slight increase over corresponding week last year.

Dudley.—The total income of the Corporation's electricity department for the year ending March last was £10,707, including £3,284 for current to private consumers, £312 motor supply, £5,603 tramway company, and £1,299 public lighting. The gross profit amounted to £5,170, of which £2,071 was absorbed in interest on mortgage loans, £2,067 repayment of loans, and £338 banker's charges, leaving a net profit for the year of £693. The loans sanctioned and borrowed for the purposes of the undertaking prior to March 31 last amounted to £63,500, and £6,762 have been repaid. The total expenditure up to the same period was £77,552. It is recommended that a further sum of £1,000, part of the amount now standing to the credit of the revenue account, be transferred to a reserve fund.

London Electric Supply Co.—The Board of Trade has granted the company sanction to an additional system of electrical supply under the following conditions: Extra high-pressure alternating-current supply to motor-generators placed in sub-stations erected above ground. From the motor-generators a continuous-current supply will be given (*a*) for ordinary lighting purposes to the consumers at low pressure, between the adjacent conductors of a three-wire system, the intermediate conductor being, with the approval of the Board of Trade, connected with earth at one point only—namely, at any sub-station supplying a distinct network; (*b*) for special purposes where the approval of the Board of Trade is given under Regulation A (1) of the Board of Trade regulations across the outer conductors of the three-wire system. The low-pressure mains will be separate or concentric cables drawn into suitable ducts, or armoured and laid direct in the ground.

Yarmouth.—An enquiry has been held into an application of the Town Council for sanction to a loan of £10,000 for electricity extensions. The Borough Surveyor said the works had commenced by supplying current for 4,523 lamps; last year the number was 34,300. The number of units had increased from 114,000 in the first year to 959,000 last year. A loss was shown up to 1898; in 1899 there was a profit of £448, followed by a loss of £751 in the next year; since then net profits had been earned ranging from £279 to £1,350 last year. The total loss was £2,701, but the total net profits in 10 years had been £6,137. In addition, £15,950 had been paid to sinking fund. The money was required for plant extensions, boilers, condensing plant, switchboard, pipes, and pumps. Mr. Gordon Bryant, the electrical engineer, said the charge to the public for current was 6d. for one hour per day and 4d. afterwards. For motors the rate was 3½d. per unit, and the rate decreased with the quantity of current taken. The committee intended now to introduce a flat rate reducing the charge to consumers.

London Power Bill.—The copy of a largely signed petition presented to the House of Lords has been sent to the President of the Board of Trade with the following letter: "Administrative County of London and District Electric Power Bill. My Lord,—The London manufacturers who petitioned the House of Lords in favour of the above Bill had briefed counsel with a view to supporting their claims before the committee, but being in favour of the Bill they were not, under the Standing Orders of the House, enabled to present their case separately. Now that the Bill is coming before the House of Commons, the signatories to that petition, who employ nearly 100,000 men, feel that the representation of their interests and the full importance of cheap power to the industries of London may be lost sight of in the discussion of other subsidiary issues, and they, therefore, pray that the Board of Trade, as the department representing the commercial interests of the country, will receive a deputation representing the manufacturing interests of London. We enclose a copy of the petition which was presented to the House of Lords." The signatories represent a total of over 250 firms employing 100,000 hands in all.

Digitized by Google

Nottingham.—The electric light fund for the past year shows stock value £1,075 in hand at the commencement of the year. Generation of electricity cost £6,435, distribution £2,128, public lamps £918, and general expenses £2,604. The receipts (including stock in hand value £1,160 on March 31 last), amounted to £25,819. 11s. 11d., the largest source of income being £19,804 received in respect of the sale of current by meter. For public lighting the committee received £3,067, and for rental of meters and motors £1,212. After meeting expenses, £12,656. 3s. 3d. was available for carrying to the net revenue account. This account showed that £2,314. 15s. 11d. was brought forward from the previous year, and ended with £2,982 to be carried forward to the current year's account. Repayment of loans last year amounted to £6,717, and interest on loans to £5,323.

Durham Collieries.—The Lambton Collieries Company, of Newcastle-on-Tyne, who recently decided to employ electrical power on a very extensive scale for haulage, pumping, coal-cutting, and lighting at their Durham collieries, have divided the contracts for the necessary electrical plant between British and German firms, the work to be carried out at a cost of over £26,000 by Messrs. Bruce Peebles and Co., Edinburgh, and by the Allgemeine Elektricitäts-Gesellschaft, of Berlin. The power is to be taken from the large power station which is being completed at Philadelphia, co. Durham, by a syndicate. The following collieries are to be equipped with electrical power: Burn Moor, Lady Ann, Lumley, Newbottle (Dorothea and Margaret), and New Herrington, in addition to the Philadelphia works. The Hetton Coal Co. are also proposing to instal electric haulage, coal-cutting, and pumping plant at their collieries in county Durham, and the Durham Electric Power Co., who are to provide the necessary power, have placed an order for a 9,000-h.p. generating station, to cost £92,000, with Messrs. Bruce Peebles and Co.

Caterham.—We are informed that, owing to increased demand for current, the Urban Electric Supply Co. have found it necessary to put down more plant at their generating station in the Croydon-road, Caterham Valley. The foundations for another boiler, engine, and dynamo were commenced some days ago, and the work is being carried out by Messrs. J. and J. Ward, of Warlingham, who were responsible for the original buildings and foundations. The new boiler will be of the water-tube type by the well-known makers, Messrs. Babcock and Wilcox, fitted with mechanical stokers, and having a heating surface of over 1,200 square feet. The dynamo, by the General Electric Co., will be capable of supplying current to 3,000 8-c.p. lamps, and is just twice the size of either of the original machines. The dynamo will be driven by engines of 120 h.p., supplied by Messrs. Bellis and Morcom, Birmingham. The mains are being extended along the Essendene, Whyteleafe, and Croydon roads, and the company will shortly lay another large feeder cable to High-street, Caterham. It is hoped by the end of the present month there will be over 7,000 lamps connected. The whole of these extensions are being carried out under the supervision of Mr. F. Bruton, resident engineer of the company.

New Marconi Stations.—The Press Association is informed that Marconi's Wireless Telegraphy Co. has received an intimation from the Marconi Wireless Telegraph Co. of Canada that the installation of the Marconi-equipped wireless telegraph stations at Sable Island and Halifax (Camperdown station), under contract with the Canadian Government, has just been completed, and that these two stations are now in full operation. Marconi wireless stations at Whittle Rocks and Cape Rich are in course of erection and equipment, and will, it is expected, be in working order by July 31, by which date it is hoped that the effective range of other Marconi stations at Cape Ray, Heath Point, and Fame Point will be increased to such an extent as to provide a complete inter-station service between the following stations on the Canadian and Newfoundland coasts: Fame Point, Heath Point, Cape Ray, Whittle Rocks, Cape Rich, Point Amour, Belle Isle, Cape Race, Halifax, and Sable Island. This service has been established by the Canadian Government primarily as an aid to navigation in Canadian waters, and with a view to establishing an efficient substitute for the land line service along the shores of the St. Lawrence, which is subject to frequent delays caused by bad weather and the breaking of cables by ice floes.

London Gazette.—At a meeting of the Tin Electro-Smelting (Lennox-yard) Co. a resolution was passed that the company be wound up voluntary, and that Mr. Alfred Leclerc be and is hereby appointed liquidator. Proofs of claims *re* the Bury, Rochdale, and Oldham Tramway Co. are to be sent in by Aug. 8, 1905, to John Coomber and Samuel Johnson, Castlemere House, Rochdale. Proofs of claims *re* the Electro-Sulphur and Light Syndicate are to be sent in by Aug. 12, 1905, to E. S. R. Wilde, liquidator, of 61½, Fore-street. The last day for receiving proofs of claims in the estate of William James Hunter, electrical engineer, etc., of 8, Norwood-street, Leeds, is July 17, 1905. A second and final dividend of 1s. 8d. in the £ has been declared in the estate of Benjamin Mountain, engineer, of Kirkstall House, Kirkstall, and at Globe-road, Leeds. Mr. W. Henry Platts, 22, Park-row, Leeds, is official receiver. At a meeting of the General Engineering Co. (Coventry) a resolution was passed that the company be wound up voluntarily, and that Thomas Mason Daffern, of Little Park-street, Coventry, be appointed liquidator. A first meeting will be held in the estate of Gerald Leslie (otherwise Gerald Algar, trading as Gerald Leslie), electrical engineer, etc., of 5, Denning-road, Hampstead, on July 14, 1905, at 11 a.m., at Bankruptcy-buildings, Carey-street, London.

Coventry.—The annual report of the Corporation electric light undertaking for the 12 months ended March 31, 1905, states that the capital expended during the year has been £15,032, bringing the total expenditure to date up to £134,503. The amount raised on loan is £149,874, while other receipts on capital account have amounted to £1,776. The total capital sanctioned is £150,033. The balance of £159 has not yet been raised. The amount of capital repaid is £29,000, and the sinking fund amounts to £12,032. During the year the number of consumers has increased from 526 to 637, and the equivalent of lamps connected from 53,746 (8 c.p.) to 71,727. Further connections are being made. The number of units sold has increased from 920,192 to 1,375 735, and the revenue from sale of current and meter rental from £10,844. 7s. 10d. to £13,247. 16s. 2d. The increase in units sold to private consumers has been from 857,242 to 1,314,267, and the revenue from this source is £11,660, against £9,581. The working expenses are £5,031, as against £4,598 in the previous year. The profit on working is therefore £8,216, as against £6 245 last year. Capital charges amount to £8,628, against £5,470 last year, and after crediting £183 for bank interest, the net result is a loss of £228, against a profit last year of £775, and a loss the year before of £189. There is a balance in the hands of the treasurer on net revenue account of £1,625, and the committee recommend that the £228 be paid out of that amount, and the balance of £1,396 carried forward to next year's account.

St. Marylebone.—The Works Committee last night submitted a report on reinstatement of trenches after laying of electric light mains, in which they stated that they had addressed a memorandum to the Electric Supply Committee stating that they were not satisfied with the manner in which the work of reinstating the trenches after electric light works had been carried out, pointing out the serious subsidence which takes place in the roads after such reinstatements, and notifying their intention to make a claim against the electricity department for any expenses the works department may be put to in properly reinstating such trenches. The committee have also decided to engage another qualified person to supervise the work of reinstating the trenches in roadways, etc., after electric light works, and to charge the cost in connection therewith to the electricity department. The Electric Supply Committee will report on the Metropolitan Electric Supply Co. (Various Powers) Bill, and will recommend that the Bill should be further opposed in the House of Commons. The committee say: "Although the Bill contains a proviso that the company cannot give a supply of electrical energy at any point in the borough of St. Marylebone except to the Council thereof, there are other provisions in the Bill which render it advisable, in the interests of the borough, for the Council to further oppose the same. As the Bill stands, it would give the company power to break up any streets in the borough which they may find it necessary to break up for the purpose of supplying the Council in bulk, or of supplying any authorised distributors in Hampstead, Hammersmith, Kensington, or Fulham. There is no restriction as to the number of trenches which may be made, as in the case of the Central Electric Bill, and the provisions in regard to the breaking-up of streets are not altogether satisfactory. The Bill would also empower the company to supply railways, tramways, etc., outside the borough, for haulage or traction, for use within the borough. This is really a power which the company have sold to the Council. As regards this power, the Bill contains a clause for the protection of the Willesden District Council, to the effect that nothing in the Act is to authorise the company to supply energy to any company, body, or person for use within the urban district of Willesden, and we think a similar protective clause should be inserted with regard to St. Marylebone." In order to safeguard the consumers' premises as regards fire risk, the fire insurance companies interested have been notified that the change of pressure will in due course be carried out, and have been requested to inspect the installations and have the policies endorsed in the usual way. As it is quite possible that at the last moment the fire insurance companies' inspectors may consider it necessary to carry out some further alterations, and there may be a few days' delay in endorsement of the policies, they have considered it advisable to make arrangements for a temporary floating loan with Lloyds, to cover any liability in connection with the matter, and have accordingly arranged for a temporary insurance to the extent of £100,000 for the purpose. With regard to change of pressure, they report that, in accordance with the regulations, they had applied to all persons occupying premises supplied before March, 1896, for their consent, and about 40 of these consumers had objected to the change. The committee had made formal application to the Board of Trade for sanction to the change without the consent of the consumers, and Mr. Honaratus Lloyd, K.C., would act on behalf of the Council for the purposes of the Board of Trade enquiry. The town clerk has been served with a statutory notice for the abatement of a nuisance caused by the emission of black smoke from one of the shafts at the generating station. The committee understand from the engineers that the black smoke was due to the fact the mechanical stokers had not been put into use, but as this had now been done the nuisance would no longer continue. Another cause which might have contributed to the nuisance was the fact that as the contractors supplying the coal for the generating station had not yet been able to deliver coal under their contract, which had only recently been entered into, a small quantity of house coal had to be used in the meantime. That cause had now also been removed, so there would probably be no further occurrence of the nuisance.

PROVISIONAL PATENTS, 1905.

JUNE 26.

13140. Improvements in and relating to electric arc lamps. Alfred William Hill and the Sir Hiram Maxim Electrical Company, Limited, The Maxim Works, Gillingham-street, Victoria, London.

13156. Improvements in automatic electric switches. Henry Birkbeck, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (The Phelps Company, United States.

Digitized by Google

13158. **Improvements in or relating to electric lamps of the character known as vapour lamps—in part applicable to other electric vapour apparatus** Charles Orme Bastian and George Calvert, Birkbeck Bank-chambers, Southampton-buildings Chancery-lane, London.

13163. **Improvements in electric machines.** William Arthel Johnson, 4, South-street, Finsbury, London. (Complete specification.)

13182. **Improvements in electric switching apparatus** Frank Michael Lewis, Norfolk House, Norfolk-street, Strand, London.

JUNE 27.

13227. **Improvements in and relating to electrical lighting or heating devices, other than crucibles.** Frederic William Vesey Fitzgerald and Hugh Stanley Revell, 97B, Regent street, London.

13228. **Improvements in telephone or like transmitters.** John Shepherd Sawrey, 40, Chancery-lane, London.

13235. **Improvements in and connected with electrically and otherwise propelled tramcars, omnibuses, and other road vehicles.** George Samuel Thompson and Marian Martha Thompson, 11, Hartham-road, Tottenham, London.

13252 **Improvements in magneto-electric machines for use in connection with ignition devices of internal-combustion engines.** Henri de la Valette, 4, South-street, Finsbury, London.

JUNE 28.

16038A/04. **Central exchange telephone system** Bertil Brander Deutsche Telephonwerke, Zeughofstrasse 7, Berlin, Germany. (Date applied for under Patents Rule 9, July 20, 1904.)

13298. **Improvements in electric automatic cut-outs with time lag element.** Edward Woodrowe Cowan and William Parnell Hamlyn, West Bank, Dishy, Cheshire.

13327. **Improvements in responders for wireless telegraphy.** William John Hancock, 111, Hatton-garden, London. (Complete specification.)

13332. **Improvements in swivelling trolley heads, current collectors, and the like.** Paul Traugott Julius Estor, 52, Chancery-lane, London.

13346. **A device for testing or detecting electrical sparking.** Frank Eugene Smith, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JUNE 29.

13378. **Improvements in thermal electric cut-outs.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

13379. **Improvements in dynamo-electric machines** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

13380. **Improvements in systems of electric control and apparatus therefor.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

13381. **Improvements in electrodes for electric arc lamps.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

13382. **Improvements in systems of motor control.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

13383. **Improvements in and relating to electric conductors** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company United States.) (Complete specification.)

13384. **Improvements in and relating to electric conductors** The British Thomson-Houston Company, Limited, 83 Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

13394. **Improvements in or connected with telephone apparatus.** Christopher John Montgomery, 15, Waterstreet, Liverpool.

13395. **Improvements in and connected with accumulators.** Alexandre Antoine Riasse, 4, Corporation-street, Manchester.

13427. **Improvements in secondary batteries.** Isidor Kitsee, 18, Fulham place, Paddington, London. (Complete specification.)

13430. **Improvements in coin-freed apparatus for the supply of gas, electricity, and the like.** John Mesney Tourtel, 146A Queen Victoria-street, London.

13464. **Improvements in and relating to wireless telegraphic apparatus.** Alessandro Artom, 7, Southampton-buildings, Chancery-lane, London.

13482. **Improvements in and relating to electric switches with enclosed fuse.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

13483. **Improvements in electric arc lamps.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

JULY 1.

13496 **Hygienic telephone attachment.** Harry James Frederick Crosby, 45 Little Humber-street, Hull.

13509. **An improved electric lamp for advertising and other purposes.** Albert Martin Lehfeldt, Long's-court, St. Martin's-street, Leicester-square, London.

13531. **Improvements in electric drills.** John Taufner and Peter Oberweis, Examiner Building, San Francisco, California, United States.

13563. **A new or improved electric ignition device or sparking plug for internal-combustion motors.** Charles Orme Bastian and George Calvert, Birkbeck Bank-chambers, Chancery-lane London.

13569. **An improved telephone attachment.** David Charles Davies, 55, Chancery-lane, London.

13577. **Improvements in or relating to electric hoists suitable for use on warships.** Clarke, Chapman, and Co., Limited, and Harry Walker, 46, Lincoln's-inn-fields, London.

13586. **Improved method of and means for supplying current to branch stations of telephone exchanges** Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske, Akt.-Ges., Germany.) (Complete specification.)

13587. **An improved starting switch for three-phase electric motors having a resistance in series with the rotor.** Siemens Bros. and Co., Limited, Hereford Berry, and Claude Martineau Toplis, Birkbeck Bank-chambers Southampton-buildings, Chancery-lane, London. (Complete specification.)

13588. **Improvements in dynamo-electric machines.** Siemens Bros. and Co., Limited, and Hereford Berry, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London (Complete specification.)

13589. **Improved method of and apparatus for cooling commutators of dynamo-electric machines.** Siemens Bros. and Co., Limited, and Hereford Berry, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13590. **An improvement in electric switches for coin-freed mechanisms, time switches, or the like** Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13597. **Improvements in sterlizer mouthpieces for telephones and the like.** Orin Henry Savage, 31, Bedford-street, Strand, London. (Complete specification.)

13605. **Improvements relating to telegraphic systems.** Pierre Picard, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Dec. 27, 1904, being date of application in Belgium.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published July 20.

1904.

14239. **Electric traction systems.** Da Kando. (Rights under Patents, etc., Act, 1901, not granted.)

14728. **Electrical measuring instruments.** Still.

14847. **Electrical fire-alarms or thermo-indicators.** Cyon.

14918 **Automatic telegraphic apparatus.** Damaskinos.

15563 **Electromagnetic signalling devices for selectively operating two or more alternate signals or the like.** Willis.

15618. **Electric circuit breakers.** Crompton and Co., Limited, and Harris.

16116. **Electromagnetic mechanism particularly for use in railway signal apparatus.** British Thomson-Houston Company, Limited. (General Electric Company.)

16422. **Manufacture of electrical resistances** Electric Equipment and Securities, Limited, and Ruzicka.

16423. **Manufacture of electrical resistances** Electric Equipment and Securities, Limited, and Ruzicka.

16425. **Manufacture of electric incandescence bodies** Electric Equipment and Securities, Limited, and Ruzicka.

17019. **Alternating-current motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

17978 **Suspending or supporting electric motors or differential gear, or both, on motor road vehicles or tramway vehicles.** Elie. (Soc. A. Vedrime et Cie.)

18359. **Incandescent electric lamp sockets** British Thomson-Houston Company, Limited. (General Electric Company.)

18361. **Resistances for electrical apparatus.** British Thomson-Houston Company, Limited. (General Electric Company.)

18446. **Mercury and the like vapour electric apparatus.** Cardan. (General Electric Company.)

18496. **Switch for electric circuits.** Farquhar.

18520. **Coin-freed gas, electric, or other meters.** Beaumont.

18704. **Electrical circuit breakers and automatic switches.** Electric and Ordnance Accessories Company, Limited, and Hall.

NOTES.

Obituary.—We regret to announce the death of Mr. William Bruce Dick, one of the original founders of the electrical engineering firm of Messrs. Dick, Kerr, and Co., who died suddenly at Carrick Grange, Sevenoaks, in his seventy-sixth year.

Society of Arts.—The council of the Society of Arts attended at Marlborough House last week, when the Prince of Wales, president of the society, presented the society's Albert Medal for 1905 to Lord Rayleigh, O.M., F.R.S., "in recognition of the influence which his researches, directed to the increase of scientific knowledge, have had upon industrial progress, by facilitating, amongst other scientific applications, the provision of accurate electrical standards, the production of improved lenses, and the development of apparatus for sound signalling at sea."

The Institution.—The *Journal* of the Institution dated June contains the following papers: "Units and Standards," with discussion; "The Alternating-Current Series Motor," by F. Creedy, with discussion; "Earthing," by Mr. W. W. Lackie (at Glasgow), with discussion; "Some Effects in Three-Phase Working," by W. M. Thornton (Newcastle), with discussion; "Mechanical Construction of Steam-Turbines and Turbo-Generators," by W. J. A. London (Manchester), with discussion; "Shunt Resistances and Temperature Compensation for Ammeters," by A. Campbell; and "The Dissymmetry of a Three-Phase System," by A. B. Field.

"Wireless."—In the House of Commons last week, Lord Stanley, referring to the Wireless Telegraphy Act, expressed a hope that on the expiry of the measure in August of next year, it would be renewed for another 12 months to see where improvements could be made in regard to the working of systems and the granting of licenses. The question of granting licenses had been found a very complicated business, and as the question of national defence was so much involved, no license had been given or refused without the full consent and approval of the Admiralty. Lord Stanley intimated that a return would be made to the House of the licenses which had been issued.

Rapid Electro-Deposition of Copper.—Mr. Sherard Cowper-Coles described before the Faraday Society on the 3rd inst. his system of depositing copper of a rapidly revolving electrode. In the first part of his paper he gave a history of other attempts to increase the rate of deposition of copper, and at the same time to secure regularity in the deposit. He then gave a number of figures to show what had been done towards obtaining a strong tube of copper by deposition on a revolving mandrel. Certain critical speeds are necessary to get the best results, and these have been determined by revolving cones and comparing the deposit at varying diameters. The success of the process is due to the fact that impurities are thrown off by centrifugal force.

Iceland.—It is reported that an agent of Messrs. Siemens and Halske has laid before the Althing (the Icelandic Parliament) a proposal for the establishment of wireless telegraphic communication between Iceland and the Continent and between four commercial towns of the island, the company agreeing to provide the installation in return for a single payment of about £36,666. The company offers to deposit a guarantee for the efficient working of the system. The yearly cost of maintenance is estimated at about £2,777. An agent of the Marconi Company has also arrived, and will submit to the Althing proposals for the installation of wireless telegraphy between Iceland and the Continent and between the four commercial towns of the island. The Marconi Company has made experiments with some success from Cornwall to Iceland.

Top-Covered Cars.—The popularity of the top cover has induced the London County Council to embark upon the fitting up with this device of a further 150 cars, for which a vote of £13,500 was approved at Tuesday's meeting of the Council. When these covers were instituted doubts were expressed as to whether they would meet with favour at all weathers, and, doubtless, their value varies somewhat with the atmospheric conditions. In inclement weather their utility can scarcely be over-rated, and, judging by accounts generally, the average receipts rule higher than in the case of the uncovered vehicle. For instance, during the period from Feb. 26 to May 27 the 100 cars of the County Council already so fitted yielded 11·83d. per car mile, as against 11·11d. for the other cars. Another 60 cars are under construction, and the 150 sanctioned on Tuesday will for the most part be distributed over the lines in the Tooting and Wandsworth districts. The work of fitting the 150 covers will, as with some of the earlier ones, be carried out by the Council's staff, the cost per car being about £90.

Radioactivity of Thorium.—An abstract of an article on this subject by Mr. Otto Sackur appears in the *Journal* of the Chemical Society. The author measured the rate of decay of the emanation of the product obtained by Hahn by the fractionation of radium barium bromide, and from the values obtained concludes that thorium emanation was evolved from a new radioactive element present in Hahn's product. The possibility of thorium itself being inactive, whilst its radioactivity is due to the presence of some other substance, is discussed. The oxalate obtained from thorianite was converted into oxide and then into chloride, which, when submitted to fractional sublimation, did not indicate any separation of the radioactive component. Barium hydroxide solution was gradually added to a solution of the sulphate obtained from the oxalate and the precipitated barium sulphate was found to be strongly radioactive, a result due to the presence of thorium X. Attempts were also made to prove the presence of a new element by electrolytic methods, which did not lead to the separation of an element of constant radioactivity, but indicated that solutions of thorium from thorianite and other minerals behave on electrolysis like dilute solutions of a new element which is strongly radioactive.

Balanced Electrodes.—Prof. W. W. Haldane Gee read before the Faraday Society last week a paper on the use of balanced electrodes in voltameters. He described a number of such instruments, especially as used in the Manchester School of Technology with considerable success. We notice that while the electrode to be weighed is supported from the balance, the connection through which the current is conveyed to the same is always moved before any weighing operation takes place. Thus the author has made no attempt to carry the current which is to be measured through the supports of the balance. With such balanced electrodes it is not enough to know the apparent weight when determining increases; readings must also be taken of the density of the solution at the beginning and end of each period of observation. From the figures given of a number of trials exceedingly accurate results have been obtained with copper, zinc, and silver solutions. Some interesting experiments with mercury electrodes are also described in the paper. We agree with the author that this type of suspended electrode is worthy of a place in the laboratory and test-room. It has the same advantage over an ammeter that an ordinary voltameter has,

Digitized by Google

and, further, it can be more quickly operated, as the plates need not be removed from the solution during the course of the experiments.

Alloys.—A demonstration was recently given by Mr. Sherard Cowper-Coles at Grosvenor-mansions, Victoria-street, of his low-temperature process for making alloys without fusing any of the metals. If a copper plate be surrounded with zinc dust and heated to 500deg. F. for about an hour, he has found that the two metals unite, and the plate becomes covered with a film of zinc, even though the temperature has never been within 200deg. of the melting-point of the latter metal. The surface of the plate becomes hardened to such an extent that it cannot be readily scratched. In the same way iron and steel articles can be covered with a uniform homogeneous layer of zinc, and, in fact, galvanised, though the advantage is claimed for this process over that of ordinary galvanising that the temperature employed being much lower the temper of steel articles is not impaired. Objects treated by this process must be free from scale, but red dust does not matter, while grease seems to be rather an advantage, so that machine work, such as bolts, nuts, and screws, may be subjected to the Sherardising process immediately after being machined, without preliminary preparation. On a large scale the operation is carried out by packing the articles to be treated in an iron drum full of zinc dust, and heated; preferably this drum should be airtight and exhausted of air to prevent formation of too much zinc oxide, or, alternatively, about 3 per cent. of carbon in a fine state of division may be added to the zinc dust.

The Municipal Tramways Association.—At the annual meeting of this association held last week in the Berners Hall, Islington, a report was considered as to the advisability of uniting the Municipal Tramways Association, the Tramways and Light Railways Association, and the Association of Tramways and Light Railways Officials. The report stated that a special joint committee, consisting of two representatives from each association, had unanimously decided in favour of the unification of the three organisations under the title of the Municipal Tramways Association. The basis of membership to this would have had to be broadened, and the other two associations would then have ceased to exist. The joint committee indicated that the municipalities could at any time hold a special meeting, at which only their own representatives would be present, in order to consider any question of policy where differencies with tramway companies would be likely to arise. After a heated discussion, however, the proposal was not accepted, and an amendment was carried referring the report back. It seems to us that this was a mistake, as one strong association would be of much more service to the tramway industry as a whole. The election of officers for the ensuing year took place at this meeting, and the following gentlemen were elected: Mr. G. B. Hamilton (Leeds), president; Councillor Boyle (Manchester), vice-chairman; and Messrs. A. L. C. Fell (L.C.C.), J. Dalrymple (Glasgow), P. Fisher (Dundee), and C. J. Spencer (Bradford), were appointed to fill vacancies on the executive committee.

Electricity and the Black Art.—There is still a lingering suspicion in the lay mind, at any rate in regard to the uneducated section of the public, that the wonders of electricity are not entirely free from the occult. This spirit of medievalism appears in the recent action of the Old German Baptists of Indianopolis, U.S.A, who at a recent conference adopted a resolution ordering all the members of the sect to discontinue the use of the telephone. The decree seems to have been received without demur. The reason given for this curious proceeding is that no warrant for its employment is to be found in Holy Writ. There is even a suggestion on the part of the sect that telephony was invented by the Evil One, though the records of the Patent Office contain a different version. Remembering the feat of Moses and the Egyptian magicians in converting rods into serpents, this reactionary community would, in logic, be bound to repose implicit belief in the legerdemain of the conjuror; but it is incapable of realising the evolution that has taken place in economic conditions since the period of the Scriptures, and presumably would bann, not only the telephone, but the telegraph, railways, tramways, and other modern developments. Marconi has cause to congratulate himself that he belongs to this age; a few centuries ago he might have shared the peril of the alchemists. The incident is more humorous than anything else, as no rational being can question the ethics of man utilising, for the benefit of the human race, the genius bestowed upon him by the Creator; but it is rather surprising that such superstition should continue to-day, even among communities noted for their eccentricity.

More Popular Science.—A writer in the issue for July 8 of our entertaining contemporary *Tit-Bits* discourses upon the repair of telegraph wires, and his omniscience so far impressed the editor that the contribution is accorded a place in "Our Premium Page" at double the usual rate of remuneration. The scribe tells how faults are located in such lucid terms that we cannot do better than reproduce his own description: "The explanation is very simple. It requires force to send electricity through a wire. The longer the wire is the greater is the force required. This force is measured; but, instead of calling it pounds, as in measuring the pressure in a boiler, electricians call the units of electrical force 'ohms.'" It will be observed that the writer lays considerable stress upon the definition of the ohm, and as he is obviously so well versed in the subject of electrical measurements it may be lamented that his knowledge was not available when the question of units and standards was recently discussed before the Institution. Still, it does come as something of a revelation to learn that the ohm is the unit of electrical force, and this prompts a correspondent at Bournemouth, in forwarding us the cutting, to inquire about the fate of the volt, so that he may keep abreast of the latest developments. Our impression is that the status of the volt has not undergone any alteration, and we are therefore constrained to infer that the writer in question has become somewhat confused in his theories. It is not necessary, or even desirable, that in a popular periodical scientific subjects should be handled precisely as they would be in a technical journal; but in these days of universal knowledge one scarcely expects to find such errors on a point with which the average schoolboy is acquainted.

Regulations for Tramway Employees.—At the fourth annual conference of the Municipal Tramways Association last week, Mr. H. E. Blain, manager of the West Ham Corporation tramways, presented a paper on "Rules and Regulations for Tramway Employés." The author necessarily treated the subject on more or less general lines, but some of his remarks in regard to rules for motormen are worthy of note. He emphasises the importance of a careful examination of the cars on their being brought out each time, the motormen at West Ham being allowed 15 minutes' pay for this. He then alludes to the economy in current that can be effected by careful driving, and the danger of accidents that may be minimised by a thorough understanding of the brakes, and a list of the instructions issued to the motormen at West Ham is given. In regard to the rectification of irregularities on the road, he points out that while it is unwise for motormen to cause delay by

Digitized by Google

endeavouring to rectify serious breakdowns, there are many little irregularities which can be localised and put right by a well-trained man. It strikes us that the essence of this latter point resides in Mr. Blain's expression, "a well-trained man." No doubt some of the motormen are quite capable of attending to these little jobs, but it is a question into which the "personal equation" enters largely; and until the motormen as a whole have been educated up to a certain standard, we doubt the wisdom of entrusting them with any but the most rudimentary repairs. Apparently West Ham does not intend to lag behind in increasing the efficiency of the drivers in this respect. In conclusion, Mr. Blain recommends that all drivers should be furnished with a guide containing explicit instructions with reference to the fall of trolley, telegraph, or telephone wires.

Heat Insulation.—Messrs. R. S. Hutton and J. R. Beard read a paper before the Faraday Society last week on the heat insulation of the materials used in furnace construction. They pointed out that too little attention is paid to the quality of the refractory materials used in furnace construction both by the manufacturers and the users. Experiments were made in the physical laboratory of Manchester University on a large number of materials such as are used in connection with metallurgical furnaces. The heat conductivity of these was found to vary over a very considerable range. Thus the material having the highest conductivity was a white Calais sand, the figure being ·00060. The lowest conductivity was that possessed by kieselguhr, which is an infusorial earth, the figure being ·00013. Firebrick was experimented with and showed a position about midway between these two as far as heat conductivity was concerned. Certain grades of magnesia were also remarkable for low heat conductivity. It is pointed out that it is by no means advisable to choose materials for furnace lining from the information obtained as to heat conductivity only, but that, other things being equal, the choice might be guided by these figures. For example, neither the light magnesia nor the infusorial earth mentioned above can withstand high temperatures for a considerable time without losing their efficiency and shrinking to a very considerable extent. In making the experiments the heat required was produced in an electric circuit. The authors conclude that whilst bricks and, generally, jacketing materials for furnaces should be of low thermal conductivity, it is of no less importance to choose crucibles, retorts, and other containing vessels which are heated externally of as high conductivity as is feasible in conjunction with their other necessary qualities. By a judicious use of the different materials and a stratified form of construction, it should be possible usefully to employ such excellent insulators as infusorial earth without risk of the damage which is inevitable if they be permanently subjected to too high a temperature.

City and Guilds of London Institute.—The full report of the council of this institute for the year ending 1904 is worthy of careful reading by all interested in technical education. It shows that the work carried on by the City Guilds of London as educational authorities is on the increase, and that the character of the education given also tends in an upward direction. The first part of the report deals with the financial question, and we regret to see that one or two of the City Companies have reduced their annual contributions to the funds. A special effort is being made to induce these companies to alter their decision, and it is pointed out that the enlargement of the Technical College at Finsbury and the larger number of students taken both there and at the Central Technical College calls for a larger degree of financial support from the various guilds. We see in the report indications that this will be forthcoming, but united action is required. The reports for the individual colleges are satisfactory, and most of the information concerning them which appears in the report has already been referred to in our columns. At the Central Technical College Prof. W. E. Dalby, M.A., M.I.C.E., has undertaken the professorship of the mechanical engineering section, which was previously held by Prof. Unwin. We are pleased to see, however, that the executive committee have appointed Prof. Unwin Emeritus Professor and that he will continue to use the laboratories of the engineering department for research work. The extensions of the mechanical engineering department of the Finsbury College were commenced when Prof. Dalby was head of the department, and will greatly extend the facilities there. It is interesting to note that the electricity required for driving the machinery in this department as well as for illuminating purposes are to be taken from an outside authority, and that special generating plant will not be laid down for the purpose. The other undertakings of the institute seem to be in an equally flourishing condition, and we are pleased to see such good reports as to the success of students who have been educated technically by the various colleges.

Physical Society.—At a meeting of the society on the 30th ult. a paper on "The Comparison of Electric Fields by Means of an Oscillating Electric Needle" was read by Mr. D. Owen. This paper describes experiments which show how an "electric needle" may be used to measure electric fields in a manner similar to that in which a magnetic field is measured by an oscillating magnetic needle. The needles used were cylindrical in form, of aluminium or of brass, and were suspended by quartz fibres three or four inches in length. The couple on the needle when disturbed from the direction of the field is proportional to the square of the field strength. For small displacements the needle vibrates isochronously, the frequency being proportional to the electric force. It may be used in alternating as well as in steady fields, and may be applied to illustrate many of the laws of electrostatics. The disturbing effect of the needle upon the field is considered; in particular its effect when placed in a uniform field. It is shown by experiments that the disturbing effect falls off rapidly with the distance from the needle, and is inappreciable (in the case of a needle 1½cm. long) at a distance of twice the length of the needle. With regard to the effect of the dimensions of the needle upon the frequency (for given field), while the restoring couple decreases rapidly with decrease of size, yet the moment of inertia decreases more rapidly, so that the smaller the needle the greater the frequency, and also the smaller the disturbing effect. The shielding effect of some dielectric materials was examined in the following way: A needle was suspended centrally in the uniform field between a pair of parallel plates. A thin-walled cylinder of the dielectric was placed around the needle, and the shielding action denoted by a fall in frequency of the needle. Glass and mica were found to effect perfect shielding. Ordinary paper shields; but when thoroughly dried by heat the electric field is transmitted undiminished, only to fall off to zero after a minute or two's exposure to the air. Dry paper soaked in melted paraffin-wax transmits the field perfectly and for an indefinite time. The paper concludes by pointing out that an electric needle suspended between a pair of parallel plates forms a simple means of measuring high voltages, since the frequency of vibration is simply proportional to the voltage between the plates.

A Novel Device for Flicker Advertisements.—The *Elektrotechnische Zeitschrift* describes a neat device recently put on the market by the Allgemeine Elektricitäts

Digitized by Google

Gesellschaft. It is in the form of a lamp socket, with one end suitable for insertion into an ordinary incandescent lamp-holder, and the other end arranged to take the lamp itself (Fig. 1). The socket contains a circuit-breaking device, as shown diagrammatically in Fig. 2. This circuit breaker consists of a small heater, similar to the heating spiral of a Nernst lamp, and of a Bregnet spring made up of two thin strips of dissimilar metals welded together.

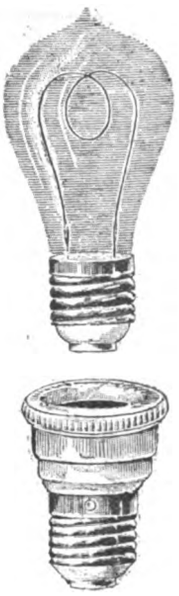

FIG. 1.

The two metals are chosen so as to have distinctly different coefficients of expansion, and in the cold state the spring is upright and closes the circuit, as shown in Fig. 2. As soon as the lamp is inserted, the current passes through the heater and the spring, and causes the spring to bend into the dotted position and so break the circuit. The spring then immediately commences to cool, and again closes the circuit. This cycle of operations repeats itself

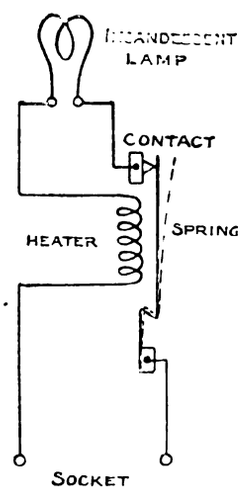

FIG. 2.

automatically at regular short intervals, and if a number of lamps fitted with the device are arranged to form an advertisement a novel and attractive effect is produced, for, though all the lamps repeat the cycle in the same time, they do not all light up or become extinguished at the same instant.

The Big Power Bill. — The promoters of the Administrative County of London and District Electrical Power Bill scored on the second reading in the House of Commons last week by the tolerably substantial majority of 40. Mr. W. R. Bousfield, in moving the second reading of the measure, stated the case for the promoters in conspicuously lucid terms. As the arguments in favour of the project are well known now, it is unnecessary to follow the hon. gentleman in detail, but it may be observed that he emphasised the possibilities of the scheme in aiding the industries of the Metropolis. He predicted, among other things, that a supply of cheap energy would revive and develop the smaller industries, which have fallen, by the way, partly through the cost of power. He showed again how the promoters would be in an advantageous position for generating current, mentioning that they had arranged for a supply of seaborne coal at a maximum price of 8s. 6d. per ton, which is much lower than the existing companies are able to purchase at. The promoters had met the objection as to their measure not containing a purchase clause by agreeing to the insertion of one which should provide for the acquisition of the undertaking on behalf of the public without any consideration for goodwill or prospective value. Mr. Bousfield concluded by remarking that if the Bill were rejected without consideration by a Select Committee, a great injustice might be done to London. Mr. Remnant moved the rejection of the Bill on the ground, apparently, of its magnitude and unfair competition, and Mr. John Burns seconded the rejection with a piece of breezy oratory. The scheme had been made in America, and had travelled to London *vid* Newcastle. He was sceptical as to the benefits it was to confer upon the unemployed, and his view of the matter was summed up in the sentence, "Better the devil you know than the devil you don't know," the existing companies presumably representing "the devil you know." Mr. Bonar Law, Permanent Secretary to the Board of Trade, defined, in a temperate speech, the attitude of that department towards the Bill, which was that it should be considered on its merits, as the question was not a political one. Personally, he was not much impressed by the pleas put forward on behalf of the municipalities and the existing companies. The former would not be justified in embarking upon an enterprise to which a certain element of speculation must attach, while the existing companies contention as to unfair competition was largely discounted by the fact that their statutory powers confined them to certain areas, and, moreover, the promoters of the new scheme, before paying any dividend, would have to supply power at a rate the present companies had never done. Further, in regard to the municipalities, he regarded their true function as residing in the supply of light, not power, and he held that they could do this to the best advantage by taking a supply of current in bulk. He thought, therefore, as did subsequent speakers, that the promoters had at least made out a case for consideration by a select committee, and this view prevailed by the majority mentioned above. This, we may add, is our own view, and the complete discussion which will now proceed of the scheme in all its bearings is to be welcomed.

The Telephone Transfer.—An announcement as to the attitude of the Select Committee towards the question of municipal telephony was made last week, when Mr. Stuart Wortley, the chairman, stated that the committee did not intend to be drawn further into the question of the management of telephones by municipalities. The question of municipal against national service would be settled on a higher ground than the consideration that municipalities may have made mistakes. Sir George Murray, secretary to the Treasury, intimated that the Treasury approved of the agreement. It was necessary to come to an early arrangement by which the company might fairly develop their business until the end of their license, and then hand their plant over to the Post Office, so that business might go on without check. Sir Robert

Digitized by Google

Hunter, secretary to the Post Office, agreed with Mr. Gaine that the Post Office could not grant new licenses to municipalities before 1911 for periods extending beyond that year without entitling the company to a corresponding extension. That was a privilege granted to the company by Parliament, and could not be taken away unless a substantial consideration was given in exchange for it, but the inability of the Postmaster-General to grant new licenses to municipalities before 1911 would not, in the long run, prejudice the question of municipalisation. It would be easier to grant new licenses in 1911 than it was now. Mr. Babington Smith, secretary to the Post Office, stated that with regard to the abolition of the unlimited service and the substitution of the measured rate, it was natural that large users should object to this because now the large user paid too little and the small consumer paid too much for his service. The past experience was too short to say what the cost of a municipal service would be, because the first year of such a service was in many respects the cheapest. If the agreement were adopted, he considered that the company would be in a less favourable position to compete with municipal authorities, because if they squeezed a local authority out the Post Office could acquire the municipal service and compete on more favourable terms. In reply to a question from the chairman as to the capital of the company being watered, the witness replied that one of the advantages of the agreement was that it entirely sets on one side any question of the company's capital, as nothing is to be purchased but tangible assets at their fair market value without any allowance for compulsory purchase or profits. Mr. R. A. Dalzell, chairman of the Central Committee of the National Telephone Staff Transfer Association, gave evidence as to the organisation of the staff. The association had a membership of 8,000, and practically included the whole of the company's staff throughout Great Britain and Ireland. He pointed out that the Postmaster-General had been receiving each year, without incurring any risk or capital expenditure, a royalty of 10 per cent. on the company's gross revenue from its exchange business, so that the staff had been partly working for the benefit of the Postmaster-General, and, through him, of the ratepayer. The claim put forward by his association was (*a*) continuity of employment, with the benefit of past services for all members of the staff in the company's service before Dec. 31, 1911; (*b*) compensation for loss of office; and (*c*) superannuation for all members occupying a post or office which, if occupied in the permanent Civil Service of the State, would entitle the occupier to a superannuation allowance or salary of £100 per annum and upwards. The Committee has adjourned till Monday.

Overhead Niagara-Toronto Transmission.—The construction of long overhead lines for the transmission of power has yet to be standardised in this country, but there is evidence that with the consent of the Board of Trade a considerable amount of such work will be done by our power companies in the near future. Thus, the South Wales Power Company are extending their distribution system in this way, and the County of Durham Power Company have in contemplation no less than 40 miles of overhead lines. This work is, however, small when compared with that now being undertaken between Niagara and Toronto. The lines in question are being erected over a private right-of-way 75 miles long, which will also be used for a high-speed electric railway to connect Toronto with Niagara. The right-of-way is 80ft. wide, and the grade at the Toronto end is not expected to exceed 15ft. per mile. Near Niagara Falls grades up to 53ft. per mile are encountered. Two independent lines of steel towers are to be erected to carry four circuits. This will allow for the transmission of 40,000 h.p. at 60,000 volts. Between the two lines of towers there will be a clear way of 34ft. for the double track of the high-speed railway. The steel towers are being placed 400ft. apart on the straight, but this distance is decreased considerably on curves. With the minimum radius of 1,637ft. the towers are placed 50ft. apart, with a change in the direction of not more than 10deg. at each tower. With wider radii the length of span is increased, being, for instance, 232ft. with a 3deg. angle between the wires, and 300ft. when the degree of change is one half. The longest span is one of 625ft., where a deep gorge has to be crossed at Twelve Mile Creek in the Erie Plateau. As regards the towers themselves, they are 46ft. from the foot to the top of the lower insulators and 51ft. 3in. to the tops of the higher insulators. The lower 6ft. of the tower is embedded in the ground, so that the insulators are respectively 40ft. and 45ft. 3in. above the ground level. The erection of these towers has been carefully thought out and the cost reduced to the lowest

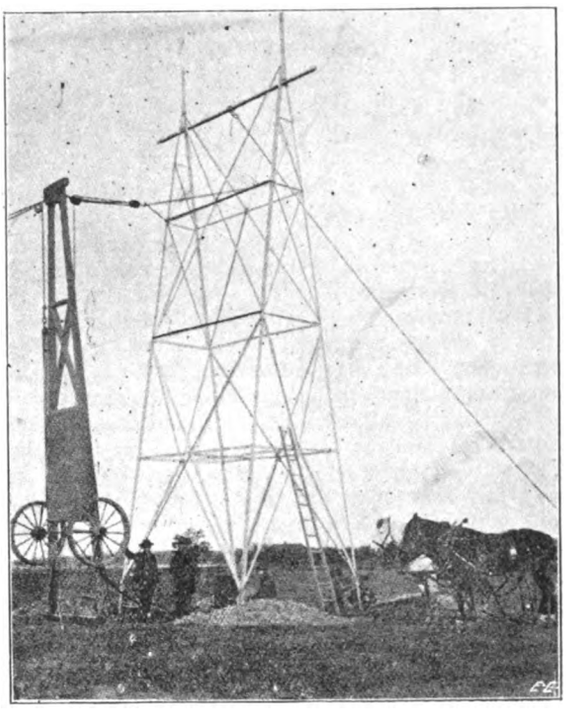

figure possible by the method shown in the accompanying illustration, which we reproduce from the *Electrical World* of New York. Each tower is brought to the place where it is to stand with all of its parts assembled, save that the extensions of the legs that go into the ground are detached. These extension pieces are first fixed in the ground with their ends projected to receive the legs of the tower. For hauling the towers a four-wheel wagon with a timber body about 30ft. long is used. When it is desired to raise a tower, two of the wheels with their axle are detached from the timber body of the wagon, and this body is then stood on end to serve as a sort of derrick. This derrick is guyed at its top on the side away from the tower, and a set of blocks and tackle is then connected to the top of the derrick and to the tower at a point about one-fourth of the distance down from its top. A rope from this set of blocks runs through a single block fixed to the base of the derrick, and then to a team of horses. On driving these horses away from the derrick, the steel tower is gradually raised on the two legs of one of its rectangular sides until it comes to a vertical position. The next operation is to bring the legs of the tower into contact with the extension pieces that are fixed in the earth, and then bolt them together.

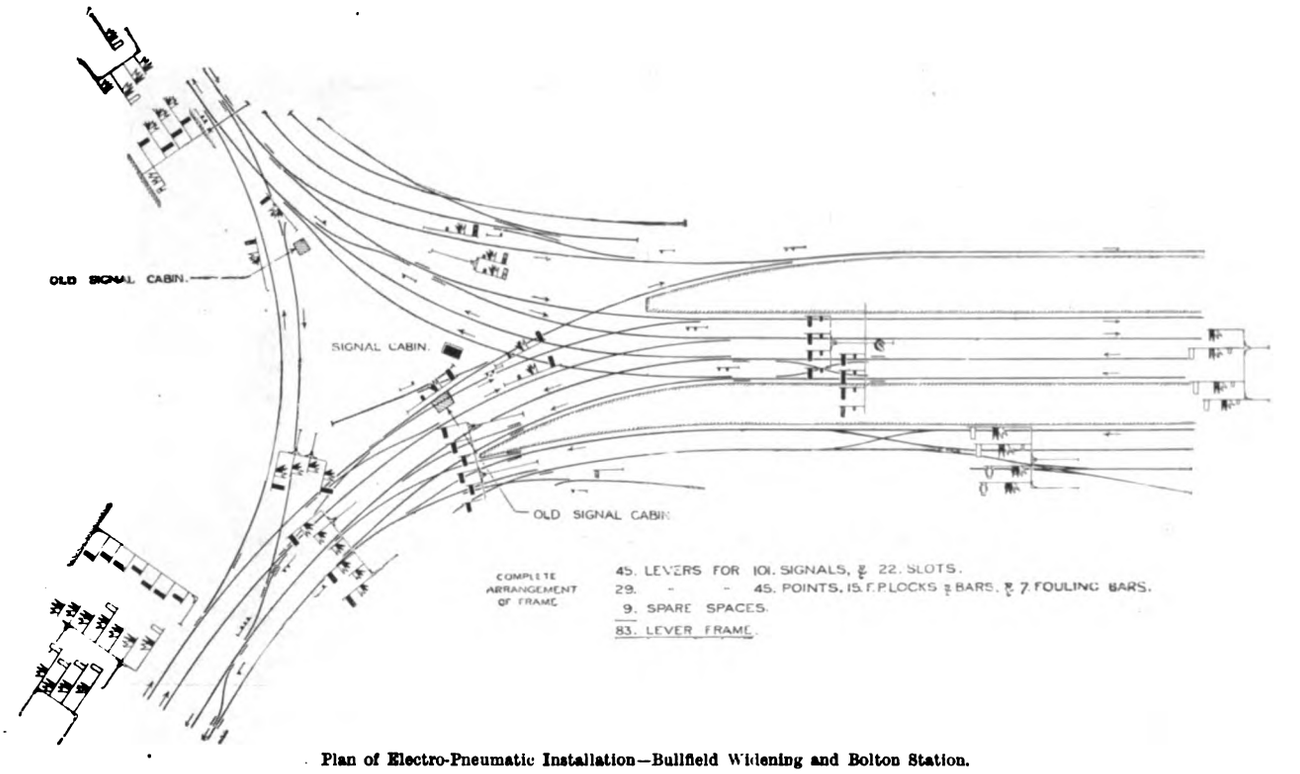
LANCASHIRE AND YORKSHIRE RAILWAY—BULLFIELD WIDENING: BOLTON.

BY VERAX.

About 64 years ago railway communication was opened through Bullfield tunnel, and during the intervening years three notable improvements have been effected. First, the main lines between Bullfield and Lostock were duplicated, whence traffic to and from Blackpool, Liverpool, or Southport could be dispatched henceforth along parallel tracks for a distance of three miles instead of being blocked outside Lostock Junction. The second distinct improvement occurred about 18 months ago, when Bolton new station, commanding the eastern entrance of Bullfield, was finished; and the splendid accommodation consequent upon the remodelling and widening of lines, marked an era in the railway affairs of this busy northern town. On the completion of the alterations before mentioned, Bullfield resembled a "bottle neck," in the sense that trains were frequently cooped inside or delayed outside the tunnel in the height of the holiday season. This serious disability will be removed on Sunday, July 16, 1905, when fast lines will be opened coincident with the demolition of the tunnel roof above the old main line, thus concluding the third and final improvement. The application of electricity for expediting and more safely controlling the traffic at Bullfield is hereafter described, and though we still hear the hackneyed phrase "electricity is only in its infancy," the readers of the *Electrical Engineer* need scarcely reminding that on a railroad, as elsewhere, electricity has passed its infantile stage; it has acquired a vigorous and fully-developed youth.



Plan of Electro-Pneumatic Installation—Bullfield Widening and Bolton Station.

Electric Signal Lamps.—It is a general aphorism amongst engine-drivers that nowhere on the line are more satisfactory signals displayed than at Bolton. This consensus of opinion is doubtless due to (*a*) the system of lighting and (*b*) the method of signalling. Some particulars of the former are here given, and reference to the latter will be considered later on under the heading of "Electro-Pneumatics." The lantern behind the red and green spectacles is fitted, inside the lid, with a hard-wood patras, from the centre of which is suspended a flexible twin cord—$^{35}/_{40}$ gauge—and a 5 c.p. 220-volt incandescent lamp connected thereto. The object of providing a short flexible cord is to protect the lamp filament from rupture when high winds are prevalent, because signal posts are subject to oscillation at such times, notwithstanding that a plentiful supply of guy wires are fixed at the resultant points. In our illustration (Fig. 1) two groups of signals are distinctly visible near the façade of Newport-street Bridge, and a somewhat similar set of semaphores are fixed at the opposite end of Bullfield. All these are electrically lighted from a pair of wires led through suitable fuses to the main switch in the signal box. It happens, however, that midway between the east and west ends there are several home signals and ground discs for the protection of numerous facing and trailing points and a cross-over road respectively; but what with grimy surroundings and high walls on either side, the efficient lighting of the signals in question required special consideration, as it would be obviously a waste of electrical energy to illuminate *all* the lamps at one moment irrespective of varying conditions. Consequently a simple rearrangement was made whereby these dozen or so lights could be left burning an hour or two longer in the morning and switched on a little earlier in the evening, independent of the remaining 700 lamps on the installation. Herein lies the advantage of electric signal lighting over other forms of illumination. Not only is it of value to be able temporarily to "light up" when the gloom preceding a thunderstorm manifests itself, but those of our readers familiar with railway work will be aware that industrial sidings, shunting necks, and carriage loops are sometimes closed for a period of four or five hours during the night, and hence, with the provision of an additional switch manipulated at the signal cabin with discretion, current can be economised with *safety*. This idea is scarcely practicable with a gas or oil system, for it is a moot point whether the cost of retaining a lampman on duty to extinguish and relight odd groups of signals would not more than counter-balance the price of gas consumed or of oil wasted. The farthest signal remote from the railway company's power-house is approximately 800 yards. Allowing for a fall of five volts at the end of the circuit, we have a system of lighting superior in brilliance to either gas or oil—a light which is not liable to be extinguished by the severity of a gale, nor the lens of the lantern obscured through smoky lampwick.

Track Circuits.—Rail treadles have rendered excellent service in past years, and even yet have a range of usefulness under certain definite conditions, but they have been superseded at Bullfield by track circuits, which perform a similar function in a more effectual manner. A treadle is an apparatus fixed to the rail itself, and actuated by the depression of the rail caused by the weight of a train passing over the spot where the treadle is fixed. This depression is utilised to complete an electrical circuit which rings a warning bell and simultaneously operates a visual indicator. It will only protect a limited distance, not ex-

Digitized by Google

ceeding one rail length, whereas a track circuit can be made to isolate a section 400 yards long quite as easily as four yards, and *vice versâ*. Lieut.-Colonel Yorke, R E, in his report on

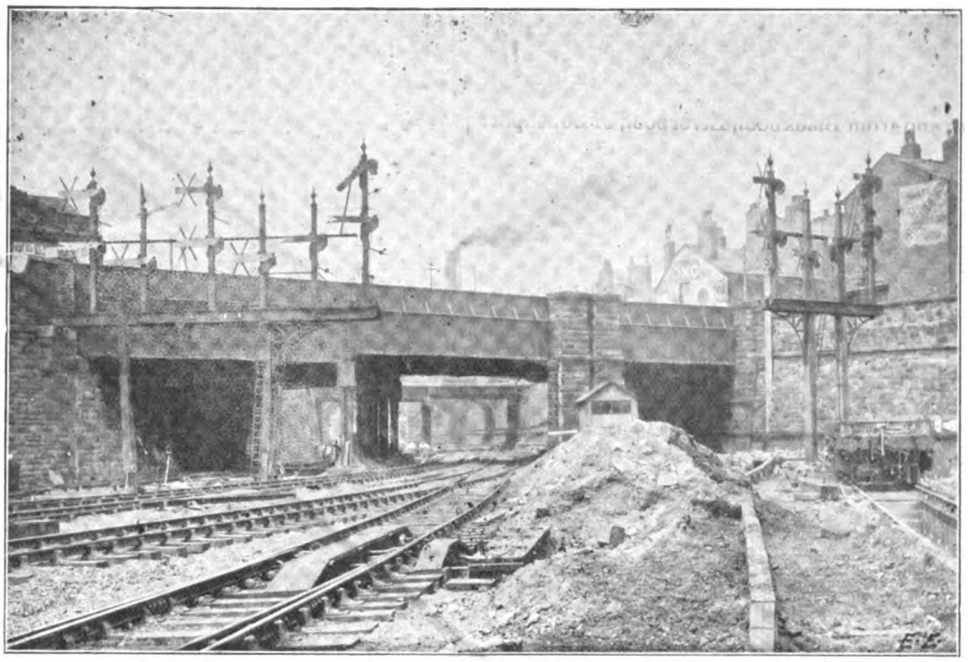


FIG. 1.—Signals commanding the entrance to Bullfield—Electrically lighted and Electro-Pneumatically operated.

a visit to America, addressed to the President of the Board of Trade—which report, by the way, was presented to both Houses of Parliament by command of his Majesty—observed that "track" circuits were extensively used in

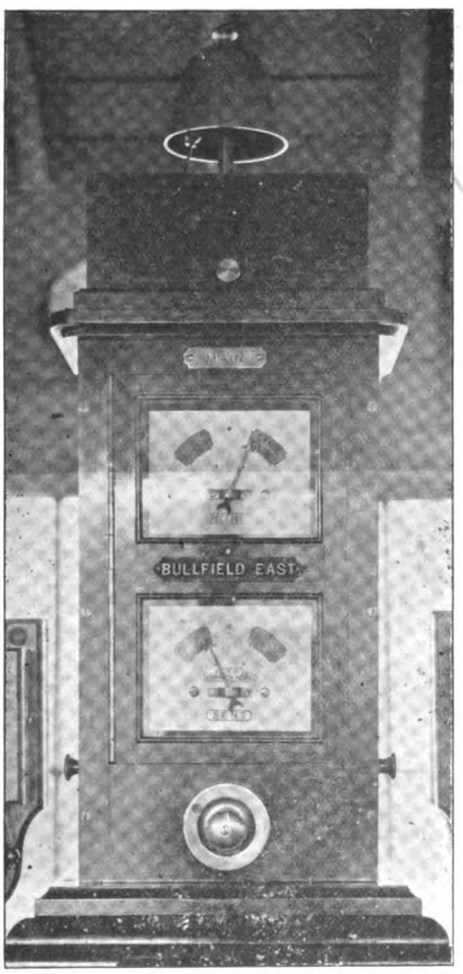

FIG. 2.—Standard Block Telegraph Apparatus, L. and Y. Railway.

the United States, and the account which that distinguished officer gave of this system is reproduced below in a brief paragraph at once cogent and explanatory: "The most modern and satisfactory mode . . . is by means of a 'track' circuit. A low-tension current flows from a battery along one rail of the track through a relay and back to the battery along the second rail. The relay makes and breaks a local circuit which controls the electric mechanism, or whatever it may be, for operating the indicator. When the current is flowing along the line, the relay completes the local circuit, and the indicator is held off. When, however, an engine or vehicle with metal wheel and axles is in the section, a short-circuit is established in the track circuit, the relay becomes inoperative, the local circuit is broken, and the indicator returns to danger." Insulated rail joints are fixed at each end of the track, and all intermediate joints are bonded to maintain good electrical continuity. In actual practice a battery of the "gravity" type has proved the most reliable for this class of work, though there was a tendency for the electrolyte to freeze in the depth of winter and thus crack the glass cell. This difficulty was surmounted by dispensing with the glass cell altogether, and a substantial teak box, dove-tailed and coated inside with marine glue, has been adopted in lieu thereof. Instead of burying the battery in a well below frost line, according to American practice, it is now placed in a wainscoted sawdust-lined cupboard 2ft. 6in. above ground, and no failure has since occurred from atmospheric causes.

Block Telegraph Apparatus.—In the accompanying illustration (Fig. 2) a combination bell and double needle telltale instrument is shown which controls the main fast lines between Bullfield and Bolton, a similar set regulating the slow line traffic. This instrument was standardised several years ago, and has undergone no modification since that time, for the simple yet sufficient reason that it combines simplicity with reliability. Where economy in shelf accommodation is not a desideratum, the block bell is always placed alongside instead of above the double-dial apparatus. The down line block needle in the top dial is actuated by the signalman at Bullfield, whilst the lower or "up" line needle repeats each movement of the commutator from Bolton West box. The plunger or ringing key works through the centre of the commutator, engaging with a vertical steel line spring inside the instrument. One 10-cell Leclanché No. 2 battery suffices to ring the bell, and four similar sized cells are ample to bring the block needles right over to the stop pins. Formerly a cumbrous route of aerial telegraphs existed, but this has been replaced by a number of air-spaced dry-cored cables laid in pitch-pine troughing along the wall side. The multifarious purposes which these cables serve may be gathered from the fact that 70 stations or cabins are connected telephonically to the signalman at either end; that local telegraph circuits, slot indicators, and repeater wires pass along this route, besides leaving a moderate margin of Post Office wires, maintained by the

Digitized by Google

railway company, whereon simplex, duplex, or quaduplex working is in full operation; and, furthermore, we understand that the introduction of superimposed telephone apparatus on these telegraph circuits is at present under consideration.

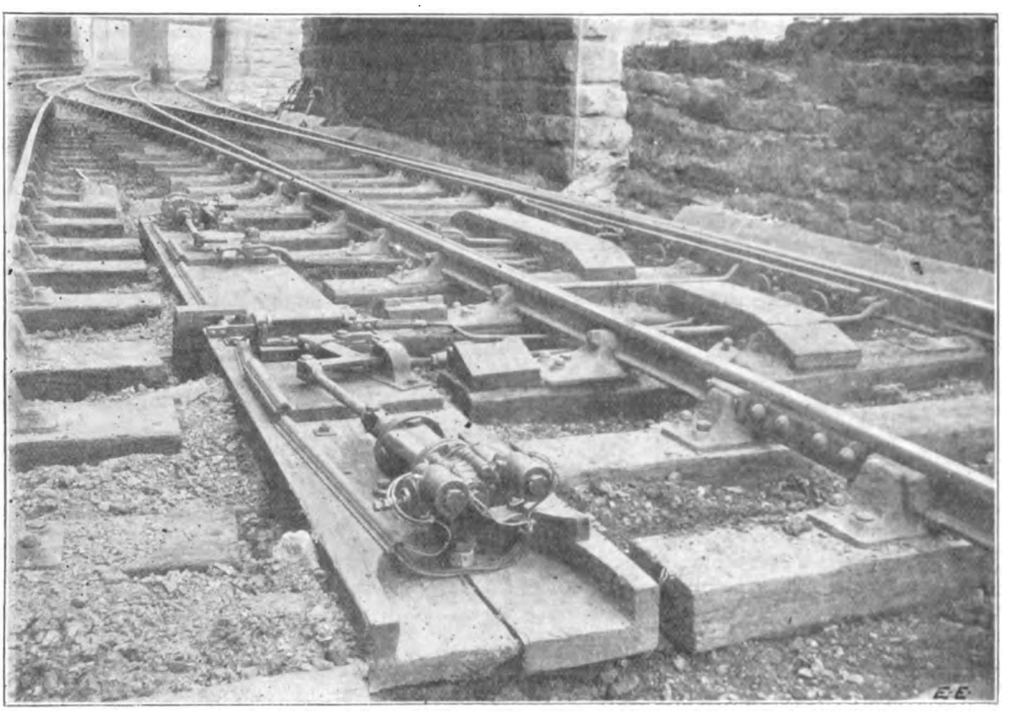

FIG. 3.—Cross-over Road Points worked by Electro-Pneumatic Power, Bullfield.

Electro-Pneumatic Signalling.—What is known in this country as the "manual" system of interlocking points and signals was in vogue along the entire length of Bullfield tunnel until about two years ago, when the whole of the mechanical appliances were scrapped, and concurrently a method of signalling was substituted on the "electro-pneumatic" principle. We have previously observed that fast lines will be opened on Sunday, the 16th inst. This new section has also been fitted with "electro-pneumatic" apparatus, and a feature worthy of note is the complete absence of signal wires, pulleys, stumps, and point rods throughout the installation—an item of moment to shunters. Engine-drivers are also satisfied with this form of signalling, because there are no "doubtful" semaphores to contend with. A signal arm must either stand at "danger" (90deg.) or "clear" (55deg.), and it is an electrical impossibility for an intermediate position to be displayed. Compressed air is utilised to actuate the points and signals, and it is the function of electricity to govern the inlet and exhaust valves of the air-cylinder by means of electro-magnets energised from the levers in the signal box. The combination is termed a motor, and such a piece of apparatus may be seen in the photograph reproduced in Fig. 3. Dry air, maintained at a pressure of 50lb per square inch in summer and 10lb. higher in winter, is transmitted through a 2in. iron pipe, and thence by branch connections to the auxiliary reservoirs located near each motor bed, where it is available as required. Current is derived from a battery of seven secondary cells joined in series, having a potential difference of 14 volts. There is an average consumption of one Board of Trade unit per day, and the fluctuation is very small at any season of the year. The reason of this will be obvious when it is explained that a current is always "to line" in the case of a point motor no matter whether the points are set in a "reverse" or "normal" position. This remark does not apply to signals because the electromagnet is only excited during the time the semaphore is held "off," and when the pointsman restores his lever to a normal or vertical position the electrical circuit is interrupted, the exhaust valve is opened, allowing the compressed air to escape from the motor cylinder, and the signal returns to danger by a counter-balance weight. The apparatus in the signal box is so contrived that the points are reversed by the first part of the stroke of the corresponding point lever in the locking frame, and when the point movement is complete, but not before, a return current from the points unlocks the point lever in the signal box, so that the signalman can only then complete its movement, and until this is done the levers operating signals in connection with those particular points cannot

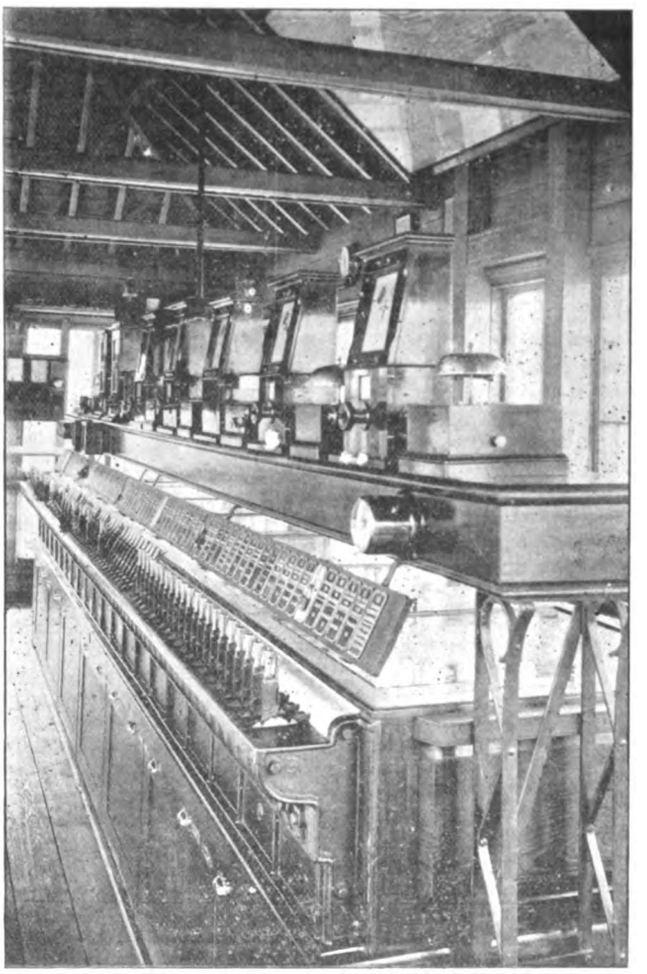

FIG. 4.—Interior of Bolton West Box.

be actuated. This is clearly a desirable safeguard, as the following incidents will show. On two occasions last winter the services of the lineman were requisitioned to attend a pair of points similar to those set forth in Fig. 3, the lever

Digitized by Google

movement for which could not be completed. In other words, "no indication" had been received in the signal box to show that the points had been properly reversed. A cursory glance as to the cause of the trouble revealed an accumulation of snow wedged between the points, and communication could not be restored until the obstruction was removed. Before concluding this article, reference should be made to a novel arrangement adopted by the railway company at their generating station in connection with the air-compressors, which latter are situate near the dynamos and booster. The old cylindrical bellows for cleansing electric machinery has been discarded in favour of a long flexible tube connected to a cock on the air-main, whence dry air at 50lb. pressure is periodically blown through the armature windings. Electrostatic action has been responsible for an accumulation of dust particles in the neighbourhood of the positive 'bus bar, and also for a discoloration behind those switchboard panels of similar polarity. It was a difficult matter to satisfactorily remove this deposit of dirt from among the live mains until compressed air became available, but under existing conditions an occasional application of dry air never fails to produce excellent results. The most noticeable contrast, however, between the old and new systems of signalling is at the pointsman's cabin (*Fig.* 4), where the present levers measure 6in. as against 45in. in the manual system; and, what is of greater importance, the physical effort required to move an electro-pneumatic lever is practically "nil" compared with the former kind, which demanded an expenditure of muscular energy in proportion to the distance of the signals or points from the cabin levers, assuming, of course, proper lubrication of the working parts.

TROLLEY STANDARDS: THEIR LIABILITY TO BECOME DANGEROUS TO THE PUBLIC, AND SOME DEVICES FOR RENDERING THEM SAFE

BY P. J. PRINGLE.

There has always been a difference of opinion as to the means which should be taken, in the interests of public safety, for preventing or assisting to prevent the possibility of a shock being obtained from the upper deck of a tramcar fitted with a trolley standard. There are many ways in which the trolley standard can become alive. For example, a blow on the trolley head resulting in injury to the insulating bush, dampness getting into same, or the trolley cable getting frayed inside the standard and the insulation finally breaking down.

Elaborate precautions are, as a rule, taken in all parts of a tramway system to safeguard the public against the risk of a shock, but the danger existent with the trolley standard has to some extent been neglected. The voltage which the trolley standard may get above earth may be anything up to the full voltage on the line, but as a rule, if the initial fault is a slight one, it very soon develops until the trolley standard is at full line potential. The top deck handrailing is, or should be, always earthed. It is very easy for a passenger to grip both it and the trolley standard at the same time. The iron legs of the seats are often in contact with the standard supporting the handrailing, and a person's foot may be placed on same while contact is made with the standard. The inside legs of the seats in some constructions are in metallic contact with the outer legs just referred to, so that passengers in passing down the centre of the top deck may easily come in contact with these legs and the standard at the same time. Any of these conditions would result in a more or less bad shock, but should it be raining and passengers' boots wet the dangerous area is increased.

From tests made between a "live" trolley standard and the metal leg of a seat (1¼in. away from handrail standard) there was a potential of 430 volts, and between the same and a metal plate, equivalent in area to that of two boots (3in. away from handrail standard and placed on the wood slats), there was a potential of 80 volts. If the metal plate was placed on the flat part of the roof (without slats), the potential was the same at 5in. distance. These potentials fall gradually, and at 2in. away from the trolley standard the potential was only 35 volts. These tests were made on the top deck thoroughly wet and on a 3ft. 6in. gauge car. Unless water can freely collect on the top deck, the potential, it will be noticed, rapidly falls off as one leaves the nearest earth connection, the handrail standard. The Board of Trade have realised this danger by requiring in their earlier regulations the fitting of ruby lamps in series with the standard and earth for approximately indicating if there is any potential on the standard. They are such firm believers in the principle of earthing to ensure absolute safety that no doubt they have considered the same principle would be best here; and the fact that they have not insisted on this is probably owing to the difficulties which might result from so doing.

The lamp method is only an approximate indication of danger, and may readily be unnoticed by the conductor or motorman for a considerable time. The revised Board of Trade regulations issued in January, 1905, require the following: "The trolley standard must be connected with earth by a low-resistance fuse or automatic switch, and the warning signal, when the fuse or switch opens, should be an electric bell." This certainly ensures that the danger shall be immediately notified, owing to the signal being audible instead of visual. At the same time, if the conductor has his car full of passengers, however smart he may be, some few seconds must elapse before the trolley can be pulled off the wire and safety ensured. One of the devices in use is the placing of a fuse in parallel with the ruby lamps, so that normally the standard is directly earthed. On the standard becoming alive, the fuse is blown and the lamps are illuminated. In another the fusing of the fuse or the operating of an automatic switch or circuit breaker may ring a bell. Another supplements this by the automatic renewal again of the earth connection by means of a switch.

The defect which would seem common to these is that the standard is earthed, and, therefore, safe as long as it has no potential on it, but immediately there is leakage sufficient to operate the fuse or automatic switch, this safeguard is removed. In the last case referred to above this removal is only for a very short instant of time, as the earth is again renewed, but it is feasible to assume that a serious shock might be obtained under these conditions. Fuses are not desirable, and have been known when working under the conditions indicated above to give a good deal of trouble. There is always a possibility that the renewing of them may be overlooked when repairing the fault. Earthing the standard, with no fuse, automatic switch, or other device in circuit, *ensures absolute safety under all conditions*, and it is only necessary to consider how this can be arranged so that the traffic and power supply conditions on the average tramway system can be met.

In some cases the trolley has been directly earthed by a continuous cable, but serious traffic difficulties have resulted from this, owing to the impossibility of bringing the car to depôt and the requisitioning of another car for this purpose. In other cases a switch has been inserted or the cable has been pulled out at the terminal to allow the car to be driven to depôt, but these arrangements are somewhat crude. If earthing the standard is to be thoroughly and efficiently carried out, the following conditions must be complied with: (1) that it is not possible for the earthing arrangement to be interfered with or removed, excepting by those authorised to do so; (2) that the earth can only be removed after danger has been declared, and not before; (3) that if the earth is removed, warning, both audible and visual, should be given; (4) that it should be impossible for the danger signal or sign to be set to safety without the earth being automatically renewed, as the omission of this important point would be serious; (5) that the leakage of a few amperes up to any current which would pass on a dead short, should operate the indicating device equally as well; (6) that it is impossible to disconnect the earth as long as any current is passing by the earth-wire. If the above combination can be obtained, it should be possible for the direct earthing of the standard to be carried out without any wilful or careless mistake being made in its operation, and traffic and power supply conditions not seriously interfered with.

On the Burton-on-Trent Corporation tramways, with

Digitized by Google

which the writer is connected, the usual ruby lamps are fitted, and while fully in sympathy with the improved regulations of the Board of Trade to ensure a more reliable indication of danger, he feels that, when meeting these requirements, they might with advantage be supplemented to give increased safety. The illustrations (Figs. 1, 2, and 3) show the device designed by the writer to fully comply with the conditions referred to above. The indicating and

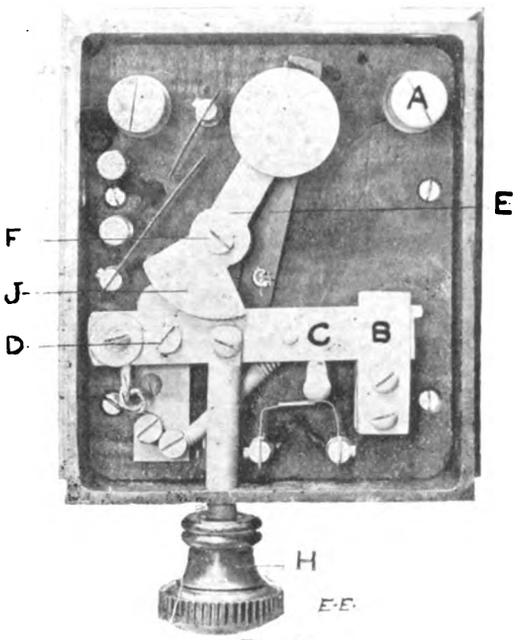

Fig. 1.

earthing apparatus is entirely enclosed in a cast-iron box, and the lid of same can be screwed down or locked if desired. The oval window shown in the cover permits a red danger flag to be shown when the apparatus is at half and also full cock. The earthing lead on the trolley standard is taken to the terminal, A, which is in connection with the switch contact, B The switchblade, C, pivoted on the screw, D, is directly connected to earth

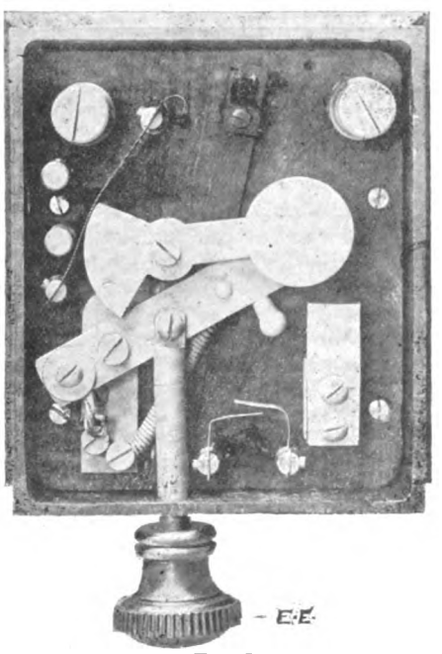

Fig. 2.

through a solenoid attached to the back of the baseboard shown. E is the indicating lever pivoted at F, fitted at its lower end with a segment piece, and at its upper end with an indicating red flag and a catch-piece which engages in the armature, G. The solenoid is wound round an iron core and G is attached to its lower end, the upper end being normally a short distance away from the pole-piece. When the indicating lever is in the position shown in the illustration, the segment piece, J, locks any movement of the earth-switch handle, H, making it impossible for the earth switch to be opened. Should a leakage develop in the trolley standard, and a small current such as three or four amperes pass to earth, this is sufficient to attract the armature, G, and release the indicator lever, E, so that it falls into a half-cock position. It is held there so long as the current continues to pass through the solenoid. When in this position, the segment, J, still continues to lock the switch handle, H, otherwise it would be possible to open the earth switch in error before the trolley is removed from the wire, with risk of danger to passengers and damage to the apparatus. As soon as the indicator lever has got to the half-cock position, the red disc becomes visible, and the two contact springs to the left of the indicator lever are brought into contact and ring either the electric car bell or a supplementary one. On the conductor removing the trolley from the trolley wire, the armature, G, regains its normal position and the indicator lever falls to full cock, the bell circuit continuing to be rung.

The interlock is now taken off the handle, H, and the earth switch can be opened. On opening the switch sufficiently far, the catch-piece at the end of the blade interlocks with the fallen indicator and is held there (Fig. 2). The opening of this switch breaks the bell circuit, but the indicator flag still shows "danger." If desired, a ruby lamp can, of course, supplement the danger indication. Once the handle, H, has been pushed up, the

Fig. 3.

earth switch is locked in the open position with the indicator at danger, and neither can be interfered with until the car has returned to depôt for repairs. On the repair being undertaken, and it is desired to remove the danger indication, all that is necessary is for the indicator lever to be pushed into its normal position, as shown in the illustration, when it is interlocked again by the armature piece. The action of moving this lever releases the earth switch blade, and a spring automatically pulls it into its normal position, causing the earth connection to be again renewed. The earth switch handle, H, is always at earth potential, the only part of the device having any potential when a leakage occurs being the switch contact, B. In the event of the fault being a comparatively small one, this usually develops quickly into a dead short, or the initial fault may be a dead short. When this is so the circuit breaker or breakers supplying the section on which the car is become operated, the solenoid demagnetised, and the indicator lever falls straightway to its full-cock position, the cycle of actions and operations being the same as before. The solenoid in an earthing device suited to the Burton-on-Trent tramways will operate with a leakage current of three to four amperes, and carry a short-circuit discharge current of 1,500 amperes.

The usual custom when a trolley standard has become alive, is to clear the top deck and proceed with the journey as far as is necessary and then return to depôt. It is always possible under these conditions for a passenger to

Digitized by Google

ascend the top deck while the conductor's attention is withdrawn. To avoid this possibility, the writer has devised in connection with the above apparatus the use of chains or bars at the bottom of both staircases to prevent access to the top deck. Arranged in conjunction with each of these chains or bars will be a contact normally closed and in parallel with the bell operating contacts connected with the earthing switchblade. With this arrangement the bell would continue to ring until both exits had been barred, the action of placing the chain or bar across causing the bell contacts to become opened. Should the earth switch be opened before the exits are barred, the alarm would still continue to ring, drawing the attention of the car attendant to this omission.

Many of those responsible for the management of tramways do not fully realise the latent danger connected with the trolley standard; that this exists there is not the shadow of a doubt, and when evidenced by the presence of 500 volts, past experience as to what this voltage can effect renders the points one which can no longer be safely ignored.

The simple device herewith described should, therefore, appeal to those whose desire is to promote the efficiency of their system, to study the public safety, and at the same time their own interests.

THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

Thirteenth Annual Meeting—Dortmund and Essen.

[FROM OUR SPECIAL CORRESPONDENT]

(*Continued from page 916, Vol. XXXV.*)

The reading of reports drawn up by the various committees is always more or less tedious except to those immediately concerned, but that business through, the remaining time is generally available for papers and discussion thereon. Not so, however, on this occasion, since a second rigmarole of welcoming speeches had to be gone through when the time arrived to meet in the Krupp-Saal of the Städtischer Saalbau, Essen, on the third day. What was said in the course of those speeches, though all very nice, need not be repeated here. The next real business was to confirm certain recommendations by the council in regard to the constitution of the Board. For the first time it was agreed to admit a member who is not an electrical engineer, but a solicitor. It is believed that benefit will be derived from this policy, since many legal questions crop up in connection with the work of the Verband, and professional advice thereon cannot fail to be of service. It was decided to accept an invitation from Stuttgart to hold the next annual meeting there. Then the president, Prof. Budde, expressed thanks to the general secretary in terms which reflected great personal appreciation of Dr. Kapp's services on behalf of the Verband during the past 11 years, and regret at his leaving them. Needless to say, these sentiments were heartily endorsed by the meeting.

It may be mentioned here that Herr G. Dettmar (formerly engineer to Messrs. Körting Bros., of Hanover, and more recently with the Lahmeyer A.G., of Frankfort) has been appointed to take over Dr. Kapp's duties as secretary to the Verband. It is well known that the editorship of the *Elektrotechnische Zeitschrift* was included in Dr. Kapp's work, but with the new arrangement this dual capacity attaching to the office ceases, I understand.

The reading and discussion of papers followed, varied by visits to works, a whole day being spent in doing the round of Krupp's large establishment. That was Wednesday. On the fifth and last day of the meeting, back in Dortmund, the programme of papers was resumed. Special reference may be made to one by Herr E. Ziehl on "Double-Field Generators for Single and Polyphase Currents." It described at some length a new form of alternator of which the Berliner Maschinenbau A.-G. have already made several examples. In construction the machine very closely resembles an ordinary slip-ring induction motor or asynchronous generator, but its method of operation is quite distinct from that of the latter. The name "double-field generator" has been selected because instead of one part—either rotor or stator—being solely employed in magnetisation, as has been the case in all electrical generators hitherto, both rotor and stator windings take part in the generation of the output current, and each of these windings, considered alone, therefore produces a field of its own. If the stator terminals of an ordinary three-phase induction motor are connected to an alternating supply, whilst the rotor is on open circuit, a current will flow so as to produce a rotating field which will set up the necessary back voltage nearly equal to the supply voltage, and also so as to supply the iron losses due to this rotating flux. Alternating voltages of the same periodicity as that of the supply are also set up in the rotor, and if the rotor windings are closed through resistances currents will be set up, and an electrical transformation of energy will take place just as in the case of a static transformer. If the rotor is set in motion mechanically, the rotor periodicity would either increase or decrease, according as the direction of rotation is against or with that of the rotating field. Thus, as the speed is increased from zero to synchronous speed—*e.g.*, 1,500 r.p.m. in the case of a four-pole motor with 50 ~ supply—in the *same* direction as the rotating field the periodicity of the rotor currents will fall from the periodicity of the supply to 0. If the speed is increased still more in the same direction, the rotor periodicity increases again until, when the rotor

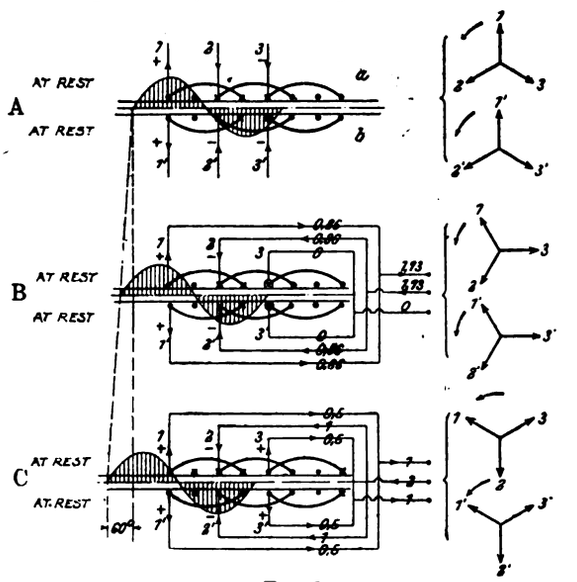

FIG. 1.

is running at double the speed of the rotating field and in the same direction as the latter, the rotor periodicity is again equal to that of the stator. Under these conditions the machine is acting partly as a transformer and partly as a generator of electrical energy, and since the frequencies in rotor and stator are alike, the attempt to make both participate in the generation of the current is at once suggested, and this suggestion forms the basis of the new generators.

In Fig. 1 *a* and *b* represent portions of the stator and rotor windings of a three-phase machine, and the stator winding, 1, 2, 3, is assumed to be equal to the rotor winding, 1′, 2′, 3′. Suppose, first, that both stator and rotor are at rest, and that in some way a rotating field moving from right to left is set up in the machine. At the instant when this field is represented by the shaded area in Fig. 1A the currents in rotor and stator will be as indicated by the dots and crosses shown, and, assuming sine wave currents, they may also be represented by the vector diagrams at the side, the upper one being for the stator and the lower one for the rotor. The currents in phases 1 and 1′, 2 and 2′, 3 and 3′ are in each case equal in amount and the same in direction; they are in phase, and rotor and stator can, therefore, be connected either in parallel or in series. In Fig. 1B, which represents the conditions after the rotating field has moved on 30deg., the phases are shown connected in parallel. Fig. 1C shows the effect of a further movement of 30deg., and it is clear that the two sets of windings behave exactly like two transformers connected in parallel.

Digitized by Google

Suppose, next, that the rotating field is produced in some way in the rotor and moves from right to left as before, but that the rotor itself is mechanically rotated in the opposite direction (left to right) at a speed which is double that of the rotating field. The stator windings will now be cut by a field rotating in the opposite direction from that shown in Fig. 1, but at the same speed as before, so that the E.M.F.'s induced in them, whilst remaining of the same amount, will be opposite in direction. The rotor windings, however, will still be cut by the same field, both as regards speed and direction, as in Fig. 1. Fig. 2 represents the new condition. Fig. 2B indicates the instant when the rotating field has moved 30deg. to the left, whilst the rotor, as a whole, has moved 60deg. to the right, producing 30deg. phase change both in the stator and in the rotor windings. The direction of rotation of the stator vector diagram is, however, reversed relatively to Fig. 1, whilst the rotor diagram remains unchanged. If the two sets of windings are again to be connected in parallel, it will be necessary (1) to interchange two of the phases of one of the windings in order to retain the correct phase equality at the junction points; and (2) also completely to reverse one of the two windings—stator or rotor—because the direction of field rotation relatively to the stator windings has been reversed.

In Fig. 2B the phases are shown connected together in this corrected manner. The rotor phases have been reversed,

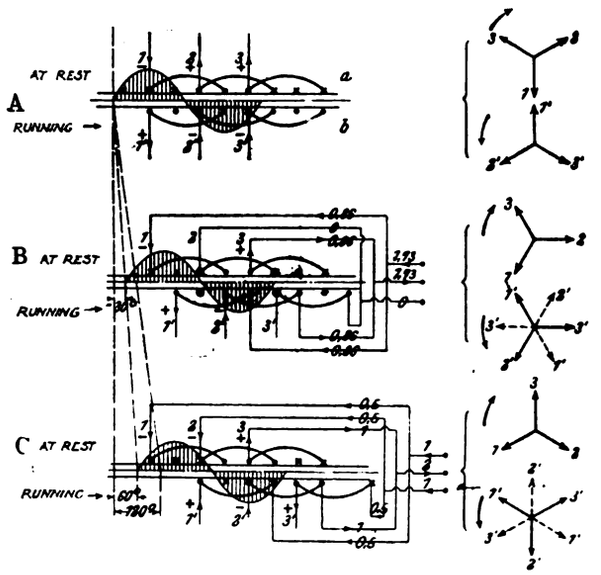

FIG. 2.

and stator phases 2 and 3 interchanged. The reversal of the rotor phases is shown by the dotted vectors. With these alterations it is clear from Figs. 2B and 2C that the two windings will theoretically again work perfectly satisfactorily together. A further interesting result is noticeable if the dots and crosses are compared in Fig. 1 and Fig. 2—viz, that in the latter case at every instant the currents on the stator are exactly equal and opposite to the corresponding rotor currents. In other words, the currents in the two windings will have no effect on the working field which passes through both in common, and there will be no armature reaction. The machine is, therefore, a compensated one, and the compensation is inherent, not artificial, as in the case of the usual type of compensated machine.

The above figures refer to a three-phase machine, but the same results, qualitatively, are obtained if a two-phase machine is considered, whilst in the case of a single-phase one (which is equivalent to Fig. 2 with phases 2 2′ and 3 3′ omitted), though the compensation is not quite complete, it is very nearly so. Under these circumstances the original rotating field would remain unaffected by armature reaction between no load and full load, and, except for the small ohmic and inductive drop in the windings, the machine would be self-regulating. The required rotating field, whose presence has been assumed above, can be introduced in various ways and will only necessitate the expenditure of a small amount of energy—viz, that corresponding to the losses which occur in an induction motor when standing still with the rotor on open circuit and the stator connected to the normal supply volts.

The most obvious way of setting up this rotating field would be to place a quite independent three-phase winding on either the stator or rotor, and to connect this to some independent three-phase supply so as to produce the field in the required position and direction. As can be seen from Fig. 1 and 2, at the instant when a particular phase has its maximum voltage, the centre of the rotating field pole must be 90deg. away from the centre of the coil of that phase, so that if the exciting energy is to come from

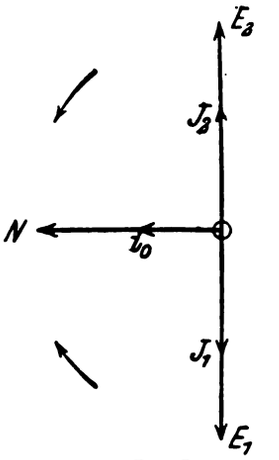

FIG. 3.

the same 'bus bars as those which the machine is to supply, it would be necessary to place the separate magnetising winding at 90deg. to the main windings, supposing that the current in the magnetising winding were in phase with the volts at its terminals. This last relation would, however, seldom exist, and as, moreover, a quite independent source of excitation has been assumed, the exact position of the exciting winding is not important, for the phase of the existing voltage would only have to be altered, so that with the particular position of exciting coils selected the required 90deg. phase difference between the field and the main winding shall be obtained.

The simple vector diagram of such a machine is shown in Fig. 3 for non inductive load and in Fig. 4 for inductive load. O N is the vector of the rotating field

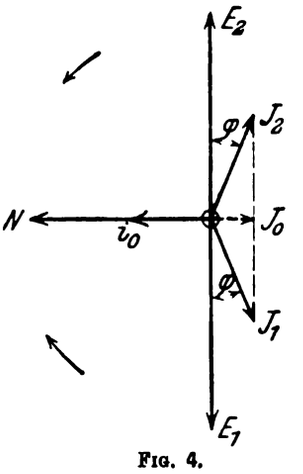

FIG. 4.

set up by the current O i_0 in a separate exciting winding. O E_1 is the induced voltage in the winding, 1′, 2′, 3′, lagging 90deg. behind the field, whilst O E_2 represents the E.M.F. induced in the other set of windings, 1, 2, 3, in opposition to O E_1, and also lagging 90deg. behind the field. The output currents are represented by O J_1 and O J_2. The two arrows indicate the opposite direction of rotation of the field relatively to the stator and rotor windings. If the numbers of turns in stator and rotor are alike, the values of O J_1 and O J_2 will also be equal. In the case of the inductive load (Fig. 4), with a lag of ϕ degrees between output current and voltage, it will be seen that the two currents are no longer in exact opposition, and so leave a

Digitized by Google

net armature reaction tending to weaken the field. As however, this field is an alternating one, it will have to maintain its full value so long as it is supplied at a constant voltage, and it will do this automatically by means of an increase in magnetising current exactly equivalent to the weakening effect of the component O J_0 (Fig. 4). In this way, even with an inductive load, the effect of armature reaction is multiplied, and, in order to maintain a close voltage regulation, it is only necessary to reduce the self-induction (leakage) of the two windings by the same means as are employed in induction motor design. When the main windings are closed-circuit ones, it is possible to discard the additional exciting winding, and use the main winding both for generating and exciting purposes. This is shown in Fig. 5, where the thick circle

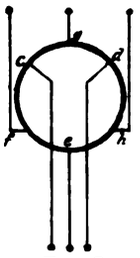

FIG. 5.

represents the closed winding on either rotor or stator with the main connections at *f g h*, and with the exciting current led in at points *c d e*, midway between the main connections. In some cases it may be worth while to produce half the excitation in the stator and half in the rotor, as this is quite possible and would tend to reduce the leakage.

All special provision for excitation (both separate windings and separate connections to the main winding) can, however, be omitted if the generator is used in parallel with one or more ordinary synchronous alternators to supply a circuit of definite voltage. The machine then acts like any other induction motor running at over synchronous speed, and takes its own exciting current automatically from the line. In fact, a "double-field generator" with a single stator and a single rotor winding used in parallel with other machines is little more than the ordinary asynchronous alternator, for in the latter it is always possible to transform up the rotor currents and use them in parallel or in series with the stator currents, or even to let the stator supply one circuit and the rotor another. The vector

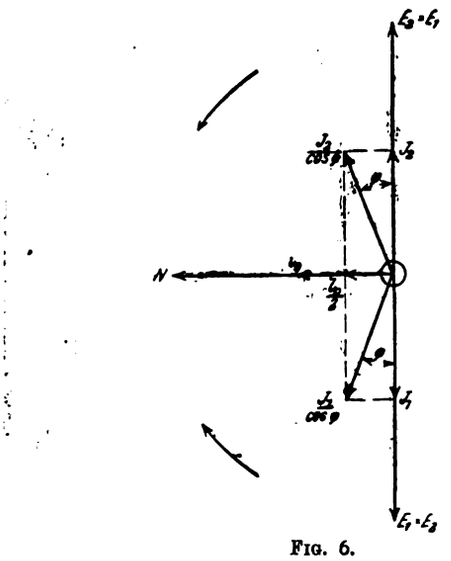

FIG. 6.

diagram of a double-field generator without separate excitation is shown in Fig. 6. Besides the load currents, J_2 and J_1, each winding (stator rotor) would have to take up a wattless current, $\frac{i_0}{2}$, equal to half the necessary magnetising current of the machine. The actual currents in the two windings would be the resultants of these two currents, and would equal $\frac{J_1}{\cos\phi}$ in the stator and $\frac{J_2}{\cos\phi}$ in the rotor, where ϕ is the angle of lag between the current and the terminal voltage in each case, and depends on i_0, or the magnetic resistance of the motor. This angle, it will be seen, is only half as great as it would be in the same machine used as an induction motor, because the stator only has to supply half the excitation. The power factor of such a generator would, therefore, always be very high. If the network on which such a generator is running is to supply an inductive load, the double-field generator would take no part in producing the necessary wattless currents. This machine would continue to supply $\frac{J_1}{\cos\phi} + \frac{J_2}{\cos\phi}$ amperes, whilst the wattless currents would have to be supplied from the network—*i.e.*, from any synchronous alternators with direct-current excitation or synchronous motors with direct-current excitation that may be on the same mains, and without at least one such machine the new generator without separate exciting circuit would be impossible.

Parallel Running.—There is no difficulty whatever about paralleling the new generators, for, if on closing the switches the phases are not correct, the effective self-induction of the two windings becomes very great, and the rotor is quickly dragged into the correct position relatively to the rotating field. Experiment has repeatedly proved this to be the case, insomuch that it is quite unnecessary to use any synchroniser. It is found sufficient if the two speeds are roughly alike as shown on a tachometer, and the machine

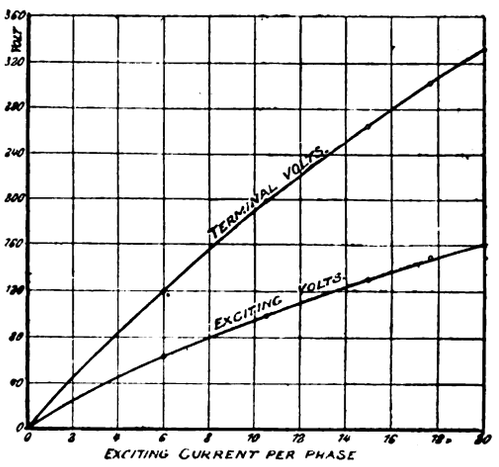

FIG. 7.

can then safely be switched direct on to the full supply voltage. When in parallel the new machines behave just like ordinary synchronous alternators, to which class they, of course, belong, seeing that they have to run absolutely synchronously. Every addition in load must be produced by a tendency on the part of the prime mover to increase the speed, and *vice versâ*, just as with ordinary alternators. If the prime mover runs too slowly, the generator becomes converted into a motor.

The properties of the new generators may be summed up as follows: In every case, whether one of the new machines is running alone or in parallel with others, and whether the excitation is produced by a separate winding or by the main windings, there must be some additional current source for the wattless currents of the machines themselves, and also for those of any other apparatus supplied from the same network. This current source may be: (1) a synchronous alternator with direct-current excitation coupled either electrically or mechanically with the double-field generators, and either taking part in supplying the load on the network or merely supplying the excitation of the double-field generators; or (2) a synchronous motor with direct-current excitation brought into synchronism with the double-field generators in some way, and then allowed to run freely in parallel with these; or (3) a combination of (1) and (2), or of (1) and (2) and a Heyland compensated and compounded asynchronous alternator, or the latter type of machine alone.

In the next place, the speed of these generators for a given number of poles and a given periodicity is double that of an ordinary alternator—*i.e.*, for a given periodicity and speed the new machines will have double as many

Digitized by Google

poles as the ordinary machines. In some cases—*e.g*, in the case of steam turbine-driven alternators—this is an advantage, for it enables either higher speeds than hitherto to be employed, or, for a given speed and periodicity, it allows more poles and a consequently lighter construction to be used. Thus, for 50 ~ a two-pole double-field machine

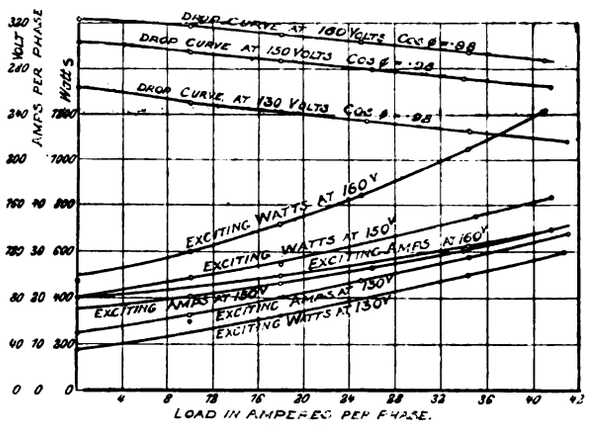

FIG. 8.

would have to run at 6,000 r.p.m. and a four-pole one at 3,000 r.p.m., instead of 3,000 and 1,500 revolutions as hitherto.

In conclusion, the results of some tests made on two of the new machines will be of interest. Figs. 7, 8, and 9 refer to tests on a 17·6 kilovolt-ampere, six-pole, double-field gene-

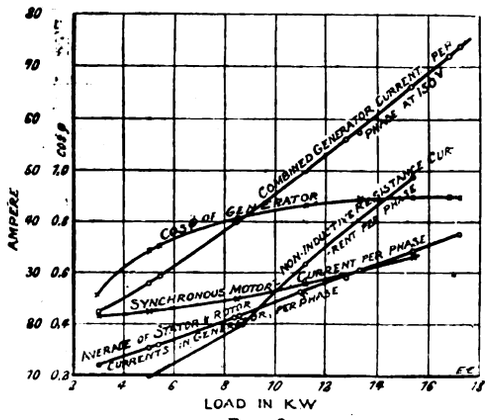

FIG. 9.

rator run at 1,600 r.p.m. and 40 ~, 300 volts, 30 amperes. This machine was built from the parts of a normal three-phase motor of 1,000 r.p.m., 50 ~, 190 volts. The rotor diameter was 300mm. and its breadth 130mm. The single air-gap was 1·25mm. Both rotor and stator had 54 slots (three per pole per phase). The rotor had 144 conductors per phase of 3·6mm. diameter wire, and the

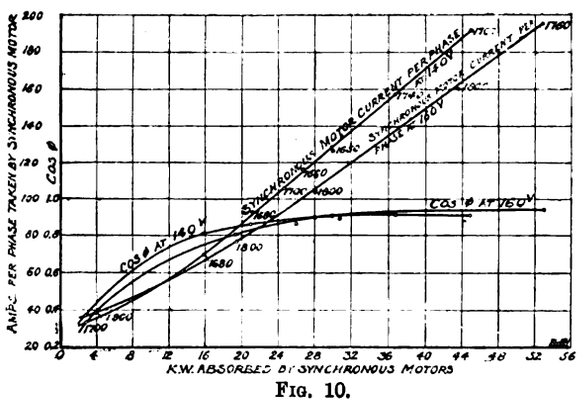

FIG. 10.

stator 141 conductors per phase of the same diameter. The exciting winding was arranged on the stator (which had enlarged slots for the purpose) at the side nearest the bore, and consisted of 141 conductors per phase of 1·8mm. diameter wire. For the tests in Figs. 7 and 8 the machine was driven by a synchronous motor, and the excitation was obtained from the same source as that supplying the synchronous motor. The main winding on the stator was connected in series with that on the rotor, so as to form a single star system. Fig. 7 shows the open circuit magnetisation curve, whilst Fig. 8 gives the voltage drop curves with various excitations, and also the curves showing the corresponding automatic increase in exciting current and exciting watts. This automatic increase is somewhat larger than would be expected, probably because the exciting winding was not quite symmetrically arranged, and gave rise to considerable leakage. The percentage magnetising current was also large owing to the large air-gap.

In Fig. 9 a test on the same generator is shown, but with the rotor and stator main windings connected in parallel for 150 volts, and with the exciting winding disconnected altogether. The generator was partly employed in driving a synchronous (direct-current excitation) motor which served to supply the wattless exciting current, and partly in supplying a non-inductive resistance load in parallel with the synchronous motor. Fig. 10 records some readings taken when the above generator and another larger generator of 32 kilovolt-amperes were running in parallel driving a synchronous motor which could be loaded up to any required extent by means of a direct-current dynamo coupled to it. The double-field generators were run at about 1,700 revolutions 42½ ~, and at 140 and 160 volts. The rotor and stator windings were in each case coupled in parallel, and no separate exciting winding was used. During the test first one machine and then the other was speeded up, and the load was transferred from one to the other. The various speeds measured are shown against the curves. In all cases both machines acted properly as generators.

(To be concluded.)

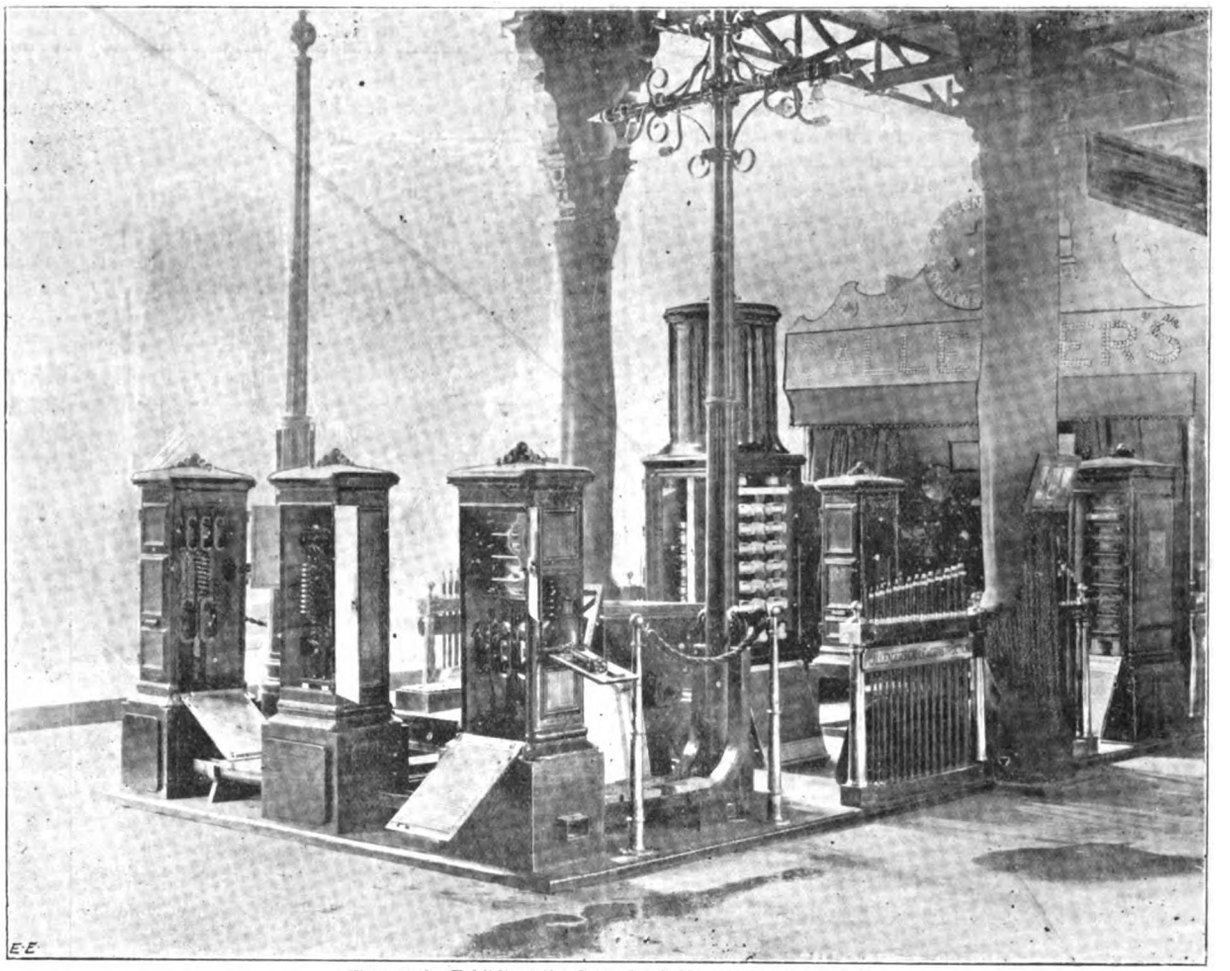
ELECTRIC TRAMWAY AND RAILWAY EXHIBITION.

(Continued from page 24.)

THE CALLENDER CABLE AND CONSTRUCTION COMPANY, LIMITED, have a splendid exhibit which well covers the wide range of cables and accessories manufactured by the firm. We noticed that there even was a tramway pole with section insulators. This was erected to show the method adopted by the company when connecting underground cables to trolley wires. The cables manufactured by this firm are so well known that a detailed description of the same would be redundant. The same cannot be said for the feeder pillars for lighting and traction work. These are exhibited in considerable variety, and special attention should be paid to the same. Amongst the most interesting is the combined distribution and transformer pillar of the type which has been supplied by the company to Hong-Kong. The pillar is made in three parts, the lower of which contains the sealing-in boxes into which the cables are led. In the next section both high and low tension fuses are placed. From these sealing-in boxes indiarubber insulating cables are taken up to the high and low tension 'bus bars in the middle section of the pillar. The high and low tension gears are carefully insulated the one from the other, and mechanically divided by an insulating shield. In the pillar we inspected there was quite a number of high-tension distributing cables provided for on the 'bus bars, which will be subjected to a working pressure of 3,000 volts. The sides of the pillar are hinged at the bottom edges, and their inner surfaces are lined with corrugated indiarubber. Thus, when the sides are let down, this rubber insulation can be stood upon, and it affords additional protection to the operators. The fuses in the high-tension connections are carried in tubes provided with the usual holes for extinguishing any arc formed. The contacts are also shielded with porcelain so as to prevent an arc striking across on to the iron framework of the pillar. The low-tension fuse gear is placed back-to-back with the high-tension distributing fuses. It is of the standard Callendar-Ward type, which is now well known. All the fittings in this pillar, and in others on the stand, are supported from the framework by two porcelain insulations. The third and upper section of the pillar is used to contain the transformer, and which can be as large

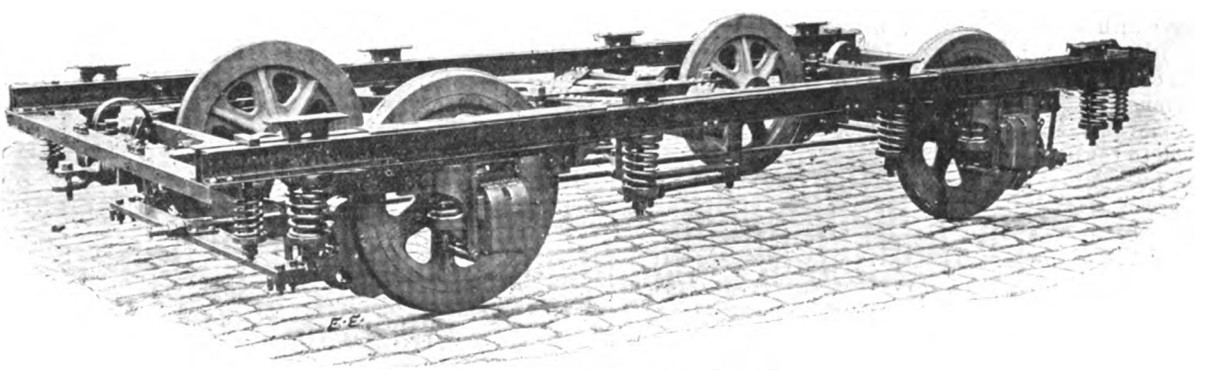
Digitized by Google

as 50 kw. Above this an arc lamp column can be carried if required. We also noticed one of the more recent forms of street boxes made by the company on the diving-bell principle. This was designed for a three-wire system, and fuses were provided in the outer conductors. Under each fuse a porcelain tray was arranged, which served a double purpose. It was so designed as to break up a band of molten fuse metal as it ascended. It also caught all of the metal, and prevented the same from being scattered over the surface of the sealing-in compound. At one end of the stand a full-size model of a tramway track to be worked on the surface system was shown to illustrate the laying of Callender cables on the solid system to such contacts. The stand itself, as shown in the photograph, was artificially fenced in by samples of cables of the great variety of types the firm have now on the market.



View of the Exhibit of the Callender Cable and Construction Co.

MESSRS. MOUNTAIN AND GIBSON, Elton Fold Works, Bury, are showing motor trucks, improved trolleys, etc., on Stand No. 24. Their "M.G." radial truck (illustrated herewith) is constructed in such a manner that the axles are free to take up independently positions radial to any curve which the truck may enter. Each of the axles is mounted in a separate sub-truck, free to pivot about a king-pin attached to the main frame of the truck, the weight being carried on eight hardened steel rollers, each of which is enclosed in a separate oil-bath, being mounted in gunmetal bearings. The sub-trucks are provided with horn blocks in which the axle boxes work in accordance with standard practice. The under side of the intermediate frame is provided with hardened steel rub-plates, bearing upon the rollers described above. The end sills of this intermediate frame are constructed of two channels with webs together stiffened over the axle boxes by means of H-section joists pressed on to them hot and then allowed to shrink. The car body is carried on eight or more spiral springs hung underneath the side sills of the intermediate frame with a view to reducing the total height of the truck. Each sub-truck is provided with a buffer arm, which bears against two strong buffer springs firmly attached to the end sills of the intermediate frame. In designing this truck, the principal aim had been to reduce the friction between the part that turns and the part that does not turn, and this has been achieved to a remarkable degree by means of the rollers which are mounted on the sub-trucks. The friction having been reduced to a minimum, it becomes possible to introduce buffer springs which are powerful enough to take up the shock experienced when a car meets a curve, thus saving considerable wear and tear on the flanges and rails and

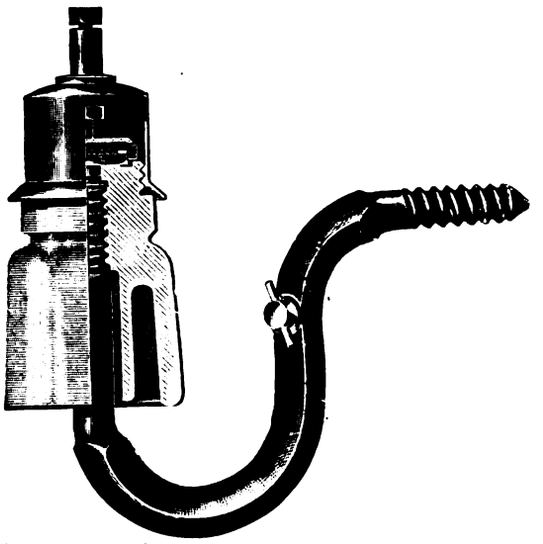


Messrs. Mountain and Gibson's "M.G." Radial Truck.

Digitized by Google

considerable inconvenience to the passengers. Beyond this, the general system of springing is designed in such a manner as to ensure easy riding both with the car empty and full, while the general construction of the truck is exceedingly stiff and strong, although simple and comparatively light. The sample exhibited is arranged as a trailer truck, being one of an order received from Messrs. G. C. Milnes, Voss, and Co. for shipment to Durban. The motor truck is very similar in design, excepting that the drawbar stays, being unnecessary, are cut out, and the motors are supported in the usual manner upon a transverse bar carried on springs supported by the end sills of the sub-trucks.

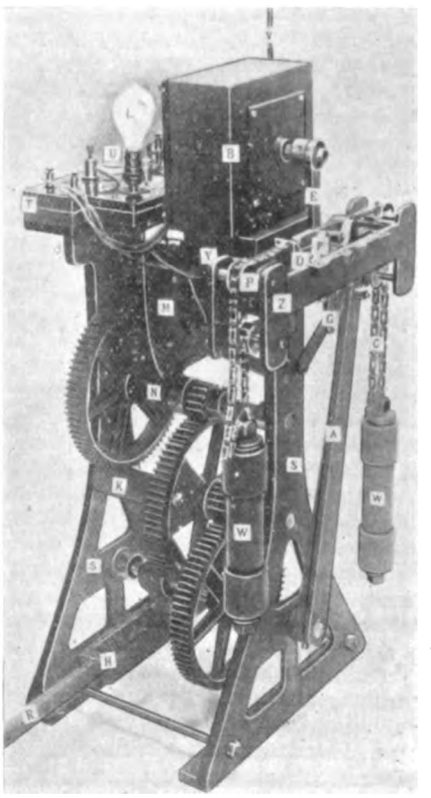
Amongst the exhibits of the BERLINER TELEPHONE COMPANY which we were unable to illustrate in our last week's issue is a combined lightning arrester and insulator for the terminal spans of telephone and electric traction lines. This is illustrated herewith. It will be seen that the arrester consists of two carbon discs, the surfaces of which are cut into V-shaped grooves, those on the lower disc lying at right angles to those on the upper. The discs are separated by a ring of mica. The whole is protected from the weather by a metal cap which screws home on to



Berliner Combined Terminal Insulator and Lightning Arrester.

an indiarubber ring, and ensures a perfectly watertight joint.

HADFIELD'S STEELFOUNDRY COMPANY, LIMITED Sheffield, make a good display with some of their specialities for tramway work, including improved patent points, 100ft., 200ft., and 250ft. radius, in best toughened cast steel with "Era" manganese steel inserts; and of solid construction in manganese steel, as supplied to the London County Council and other important corporations. These points can be supplied in any length up to 15ft., and are so designed that the tongues are of the maximum strength consistent with smooth running, inasmuch as they are the same width on the base for their full length. The box on the side of the point not only gives efficient drainage, but is so arranged that it is suitable for the mechanism of either a movable or an automatic point, and the conversion from one to the other can be performed in a few minutes without interfering with the track or interrupting the ordinary car service. A very interesting exhibit is a set of the company's steel-tyred car-wheels which gave a mileage of 79,680 on the Sheffield Corporation tramways before being taken out of active service. Each of these wheels is composed of a cast-steel centre, fitted with a special rolled-steel tyre. A working model of Le Rossignol's patent unbroken main-line cross-over, as adopted by the Newcastle Corporation, is included in the exhibit. This is an exceedingly simple device, and has given complete satisfaction in use we understand. But from an electrical point of view a more interesting item is Parr's patent automatic electrical point controller. This device, which we are able to illustrate herewith, is the invention of Mr. G. D. Aspinall Parr, M.Sc., M.I.E.E., etc., and has already been adopted on several large tramway systems. It is put into operation by the driver of any moving electric car or train simply actuating the ordinary motor controller employed by him in driving, and is not injuriously affected by damp, being a thorough engineering appliance, at once understood by any ordinary mechanic. Moreover, the point controller can be "set" so that the driver cannot operate and "take" his points above a certain prearranged car speed, and is unaffected in its action by a variation of 150 volts in 550 volts. The whole machine is mounted on two strong standards, S S, which carry an electromotor, M, capable of driving a train of spur gear wheels. The bottom shaft of this train actuates the rail point, the hauling rod, R, and link, H, also the conductor point in either underground conduit or surface systems, whilst by a flexible or other suitable hauling rope, V, it actuates the conductor point in overhead systems. The direction of rotation of the motor, M, and hence the position of the points, is controlled by a reversing switch fixed to the front of the box, B This switch is of simple construction, has an exceedingly quick break, and its spindle is actuated by the arm, E. This arm, E, is in turn actuated by a stout phosphor-bronze slider, D, which is worked by one or other of two falling weights, W W, attached to it by strong chains, C. The slider, which works



Parr's Automatic Electrical Point Controller.

on a guide bar, is caught and released by the plunger of a specially designed electromagnet, Y, and the arm, E, is controlled by a double-ended latch, F, itself released by an arm, G. The slider, its guide bar, the latch and pulleys, P, over which the chains roll, are all carried by the stout frame, Z. An arm, A, actuated by the bottom shaft, raises the weights, W, alternately, moving with the points from one side to the other. A terminal board, T, carrying the necessary terminals, fuse block, U, and lamp or other resistance, L, interconnects the reversing switch, motor, electromagnet, and source of supply. The box, B, contains nothing but the necessary spring for controlling the arm, E, while affording convenient bearings for the spindle of the switch. The motor, M, is of the enclosed type, with self-lubricating bearings, carbon brushes, and is non-sparking. It would be quite sufficient to oil this once a year, and other moving parts once a month. The machine is contained in a neat cast-iron street box, 19in. square by about the usual height of the ordinary street feeder box. This box is specially designed to enable the whole machine to be got at in less than half a minute, and the controller can, if necessary, be actuated from the

Digitized by Google

outside of the box, in case the driver passes the overhead contact with current *off* or *on* when it should have been otherwise. A light contact is attached to the electrical conductor through the medium of which the auto-controller is operated.

(To be continued.)

SHEFFIELD UNIVERSITY.

The new buildings of this university were opened by the King on Wednesday last. They contain provision for the teaching of a wide range of technical subjects, including electrical engineering. The physical laboratories have a superficial area of 9,950 square feet, and are self-contained on three floors connected by a spiral staircase and apparatus lift; the rooms on each floor being arranged on either side of a central corridor except those on the lower ground floor, which, owing to the slope of the ground, are confined to the quadrangle front. Accommodation is provided for all the various departments of physics, except electrical engineering, which is housed in the buildings for applied science in St. George's-square.

The various laboratories and lecture-rooms are connected by air-insulated bare stretched copper wire to an exchange board on the middle floor, so that it is possible to connect any apparatus in one room with one in another, either for calibration, time signals, arbitrary E.M.F.'s, or similar purposes. An eight-volt circuit for galvanometer scale lamps is led round each room where such lamps are required. Two continuous circuits, each of 60 volts, and two alternating circuits of 200 volts, differing 90deg. in phase, are also laid down throughout the laboratories, the continuous circuit consisting of twisted twin cable. The alternating circuit is served from the Corporation mains.

The rooms in this department on the lower ground floor are the battery and dynamo rooms, the workshop, and a constant temperature room with double walls and ceiling. The battery-room contains two batteries of 32 L. 15 E.P.S. cells; in the dynamo-room is a Siemens dynamo, driven directly by a Thomson-Houston 7½-h.p. motor; also a Whitehead compressor and a Brin air-liquefying apparatus, driven by the same motor. The workshop, which comes next to the dynamo-room, is fitted with various lathes, etc., driven by a 1½-h.p. Thomson-Houston motor, from a shafting independent of the walls, the design being to equip it so that it may be used not only for the construction or repair of ordinary apparatus, but to manufacture special apparatus for purposes of research.

The upper ground floor is only a ground floor on the park or west side. On this side, going from north to south, are a large balance room for ordinary students, and a room, with north outlook, to be used for magnetic measurements. The room contains a standard clock, which is, for rating purposes, to be connected by an underground wire with the standard transit instrument in the park, presented to the university by Pembroke College, Cambridge.

The new buildings allotted to the engineering department consist of four floors; the lowest floor or basement contains a large extension of the original laboratories. The main engineering laboratory contains a plant which can be used both by mechanical and electrical engineering students; the equipment of this laboratory provides for an all-round training in the practical study of the leading types of prime movers, including steam, gas, and oil engines, air-compressors, and hydraulic machinery. There is also a very complete electrical equipment in the new building to demonstrate the applications of electricity to lighting, traction, and power transmission. The upper floors of this building are fitted up as administrative offices, lecture-rooms, and laboratories. The older part of the building contains all such appliances and machinery as are required for the training of mechanical, civil, and electrical engineers.

The King, replying to an address of welcome from the city, said: "I have great pleasure in receiving, on behalf of the Queen and myself, your loyal and dutiful address. We retain a pleasant recollection of our previous visit to Sheffield, and are glad to be present here to open the university buildings, and to inaugurate a work which I am well assured will tend to promote the advancement of knowledge and the spread of culture among all classes of my people in the city. I have no doubt that the establishment of the university in this large commercial centre will also afford facilities for the technical training which is now essential to success in every industrial enterprise. We shall follow the progress of the university with warm interest, and the welfare of your city will always be the subject of our sincere good wishes."

In reply to an address from the Chamber of Commerce, he said: "I feel assured that the establishment of the university in Sheffield will do much to foster that spirit of enterprise which has been so distinguished a characteristic of British commerce in the past, and to encourage the spread of that technical and scientific training which is more than ever necessary to enable this country to hold its place in the field of commerce amongst the nations of the world."

DARTFORD TRAMWAYS.

The ceremony of laying the first rails of the Dartford tramways took place on Wednesday last at the terminus of the Bexleyheath track, a number of guests being witnesses, at the invitation of the chairman of the Tramways Committee, Mr. S. K. Keyes. The event is noteworthy in that it marks gratifying progress with the time's requirements. In some districts inter-urban communication by tramways has been checked by petty jealousies between neighbouring authorities, but not so in the case under notice. When the Dartford tramways are complete, there will then remain but a short gap to break the continuity of track between Gravesend and London, a distance of over 20 miles, while the branch systems to the north and south will act as feeders to the main line of route. The Dartford tramways will link the existing track of the Bexleyheath Council with the Gravesend system. They will be of single-track construction with turnouts, the total length being about 8¾ miles. Messrs. J. G. White and Co., Limited, are the contractors for the whole of the track work, overhead equipment, and cars. The rails, to be laid on concrete, will be supplied by the North-Eastern Steel Company, all special track work being by Messrs. Hadfields Limited, and continuous rail joints are to be used. As regards the overhead work, chiefly bracket-arm construction with double trolley wires is to be employed. On the flat the track will be paved with Norwegian granite bordered with Guernsey granite in the town proper, while Welsh non-slippery granite will be used on the hills. The stiffest gradient is about 1 in 12. The contract for the cables has not yet been settled, but it may be mentioned that the feeders are to be laid solid under the footways. Additional plant is to be installed at the Urban District Council's existing electricity works to meet the requirements of the traction load. This plant will comprise a Lancashire boiler by Messrs. Ruston, Proctor, and Co., Limited, a 200-kw. Fowler generator coupled to a high-speed engine by Messrs. Browett, Lindley, and Co., Limited, an E.P.S. battery, a booster which will be supplied by the Lancashire Dynamo and Motor Company, Limited, and a Ferranti traction-type switchboard. The rolling-stock will comprise 12 cars of the double-deck type, each capable of seating 50 passengers. These cars are to be supplied under a sub-contract by Messrs. Dick, Kerr, and Co., Limited. They will be fitted with Westinghouse magnetic brakes. The Council have entered into a separate contract for the construction of car-sheds.

It remains to add that the Council have arranged to lease the tramways when completed to Messrs. J. G. White and Co., Limited, for five, ten, or fifteen years at the option of the Council, the company on their part guaranteeing interest and sinking fund on the capital outlay, in addition to 20 per cent. of any profit which may be made on the working of the system. Under their agreement the Council will supply current to the company on a sliding scale of 2d. for the first 100,000 units, 1¾d. for the next 50,000 units, and 1½d. for any excess, as metered at the station switchboard. The consulting work in connection with the scheme is in the capable hands of Messrs. Hawtayne and Zeden,

GLASGOW AND BOSTON TRAMWAYS.

Mr. Hayes Robbins has contributed a long article to the American *Journal of Sociology* on the question of municipal tramways. The author in this attempts to draw firm conclusions as to the relative efficiency of municipal and company mangement from a full comparison of the tramway systems in Glasgow and Boston respectively. The task would have been no light one had the two systems been in one country, as even then local conditions have to be allowed for when making comparisons. With two towns—one in Scotland and the other in the States—the figures are influenced by so many engineering and social differences that they can never be comparable. Still, the author has taken a great deal of trouble over the matter, and some of his points are worthy of consideration. They show clearly the great difference between the two systems. The Glasgow figures quoted are rather old, but this does not introduce any great error into the comparison. The author credits Glasgow with 139 miles of single track, with an average cost of £20,623 per mile. As against this the Boston Elevated Railway Company operates 440 miles of single track, on which the capital averages £22,000 per mile. This is said to show that the Boston company is not over-capitalised, but it does not indicate the well-known fact that the power station and plant of the Glasgow tramway department are very much larger than is required. The following averages as to the services rendered by the two systems are of interest:

"Glasgow has one mile of track for every 7,200 of population, in round numbers; Boston, one mile for every 2,270. The Glasgow system in 1902-3 carried 177,179,594 passengers; the Boston company carried about 236,000,000 paying passengers, of whom 130,000,000 used free transfers, making 366,000,000 separate trips furnished. The average daily traffic is: Glasgow, 485,000; Boston, 1,000,000. The Glasgow rolling-stock consists of about 680 cars of all kinds; the Boston company owns over 3,300. The average number of cars operated in one day in Glasgow is now about 450; in Boston, 1,300. Thus Boston operates one car for every 770 passengers carried each day; Glasgow, one car for every 1,077. This difference is reduced, however, by the fact that practically all the Glasgow cars are 'double-deckers,' seating from 50 to 55 passengers."

Such double-deck cars have not met with favour in the States. The author does not mention the passengers carried each year per mile of track, which works out to 1,275,000 in Glasgow as against 832,000 in Boston. The density of the traffic is thus quite 50 per cent. higher in Glasgow than in Boston, which speaks well for municipal organisation. The question of fares is also dealt with, and the author favours the American system of uniform charges almost irrespective of distance. He considers that our system prevents the spread of population into the rural areas. Be that as it may, the Boston public cannot ride anywhere for less than a twopence-halfpenny fare, whilst at Glasgow for the period in question 36 per cent. of the passengers paid one halfpenny only and 56 per cent. paid one penny. The remaining 8 per cent. paid more and rode further. The distances one can travel on the Glasgow tramways are less than those on the Boston system. Thus the most distant suburban point to which the Glasgow tramways extend is Paisley, 6·95 miles. To get there costs 3d., or 3½d. from the centre of the city The next farthest point is Clydebank, 6·39 miles, fare 3d Three other suburbs are between four and five miles, and one about three and a third. From Park-street Station, Boston, a passenger may ride 9·53 miles to Arlington Heights for 2½d., 9·83 miles to Charles River Bridge,

Digitized by Google

8·23 miles to Arlington Centre, eight miles to Waverley, 7·9 miles to Melrose line, 7·36 miles to Milton, 7·3 miles to Neponset, 6·32 miles to Woodlawn, and 6·04 miles to Lake-street, and the uniform fare for any one of these journeys, or for any two of them in combination, through free transfer, is 2½d.

These figures are interesting, but any reduction in the fares for the long-distance journeys in Glasgow would only affect a very small proportion of the travelling public. On the other hand, the halfpenny fares and the longer penny stages provide travelling facilities which are universally enjoyed. Other parts of this article deal with the contributions to the public funds out of profits, the rates of wages paid to employés, etc. Mr. Robbins concludes that while public ownership and operation of street railways, under the favourable civic conditions of British municipalities, in most cases give a better and cheaper service than was afforded by the various private corporations it supplanted, even this improved service is relatively meagre in extent and usually of mediocre quality compared with American experience, and that the municipalised enterprises would break down entirely if subjected to any such tests as are commonly required under American conditions. In our opinion, the first conclusion is justified, and it would apply equally in the States if civic government there was purified. There is nothing in the figures to justify the second and third conclusions. It would seem rather that the Glasgow conditions provide a denser traffic than is found in Boston, and this is dealt with at fares which are not approached in the latter town. More useful comparison will be possible when Chicago figures under municipal management are available.

REVIEWS.

Elektrisch betriebene Strassenbahnen. Taschenbuch fuer deren Berechnung, etc. By S. HERZOG R. OLDENBOURG.

Engineering pocket-books have multiplied to such an extent of recent years and the treatment of the respective subjects differs so under the compilers, that it has become necessary to place these works in one or another of at least two categories according to the treatment. On the one hand, we have the pocket-book which contains not only a collection of formulæ and tables of data, but which also gives in brief the theoretical basis of the formulæ and a certain amount of mathematics and pure science. Such books generally contain descriptions and diagrams of nearly all the attempted applications of the scientific principles dealt with in the book. On the other hand, we have the pocket-book which is almost entirely a compilation of tables of data, and of diagrams of arrangements and connections, and which as often as not also gives exhaustive lists of the principal dimensions of standard machinery and apparatus manufactured by leading firms. Books in this latter category do not, as a rule, contain many formulæ, and do not give any account of how the formulæ they do give are to be arrived at. Books which fall properly into this latter category are of especial use as handy books of reference to save calculation, etc., and are, no doubt, welcomed as such by draughtsmen and estimating clerks. Those in the former category, however, appear to have a somewhat wider range of usefulness, although as a rule they are lacking in those particular features which would make them invaluable time-savers in the class of work just referred to. The pocket-book under review aims at fulfilling the functions of both classes, and to a very large extent succeeds in so doing. While, however, the tables are remarkably complete and well arranged, so that they cannot fail to be appreciated in the drawing and estimating offices, the earlier parts of the book do not appear to be so well carried out.

The treatment is divided into five sections: (1) the design and erection; (2) schedules of statistics to be compiled and estimates of capital and revenue, specifications; (3) working regulations and estimate of working costs; (4) safety regulations and service rules; (5) tables.

Section (1) is remarkably complete, in that it takes in review the whole undertaking, from the central station and car-shed to the rails and bedding, not omitting the building requirements. But while it is thus exceptionally comprehensive, it is uneven in attention to details, and, what is much more important, it fails to discriminate sufficiently between those methods which have been attempted only (all of which are described) and those which experience has shown to be worthy of adoption in practice. This is noticeably the case in the portion dealing with systems other than overhead trolley wires. Apparently every surface-contact scheme and every conduit scheme that has ever been put into operation, even in an experimental way, is included and described, but no word is said to indicate that many of these have proved failures or have failed to passed the experimental stage. It may be urged that an engineer well knows which systems have and which have not proved successful, but this is surely just where the pocket-book should come in as a source of information. An engineer may well be expected to know the failure or success of the systems that have been employed in his own country, or in the most important cities of the world, but with electric traction spreading on all hands, and even, one may say, to the most remote corners of the earth, few, indeed, are the engineers who are able to keep themselves conversant with *all* that is going one. Hence, too, arises the necessity for very frequent revision of such pocket-books as fall partly or entirely in the first of our two categories. The first portion of the book is also somewhat weak in dealing with the regulating devices for governing turbines, while the various arrangements so largely in vogue in the present day are inadequately treated. Most of the descriptions, on the other hand, are exceedingly thorough and clear, no pains having been spared in this direction to include illustrations of everything that could possibly be of use. The erection of trolley wires receives very complete and careful treatment. We do not remember having seen in any pocket-book such a really satisfactory and detailed description of the right methods to be adopted and the precautions to be made against the numerous pitfalls to be met with. The Board of Trade regulations in force in this country are, naturally enough, omitted, and this is a somewhat serious drawback to the usefulness of the book in this country, since these regulations and the details of the so-called Board of Trade panel, whatever opinion one may have of their real usefulness, should certainly receive careful attention in such a work.

The annealing of cast solid joints is very properly insisted upon, and the processes are well described and dealt with. On the whole, the earlier portion of the book is full of very excellent matter, with timely warnings against dangers and traps which the unwary engineer might fall into, and its chief fault appears to us to be the want of discrimination above referred to between what is present-day practice and what is merely experimental.

Section (1) is also weak in its treatment of turbine regulating devices; steam-turbines are dismissed in a brief page, and gas-engines in little more. Most of the remaining descriptions are good and clear, with the exception of that dealing with the overhead construction adopted on curves where a trolley bow is used instead of a trolley wheel. No reference is made to soldered rail bonds, which, in America at least, are now meeting with considerable favour.

The second portion dealing with the projecting of a tramway and with the calculation of the probable income from it, and with specifications for tender, is good, but does not appear to merit special remark, while the third portion is so superficial that it might almost be omitted. The fourth portion, dealing with various police and other regulations, has little or no reference to this country, and is of little service here except, perhaps, as affording a few suggestions by way of improvement in the existing British regulations.

In conclusion, the book appears to be a decidedly useful one, and the first and fifth sections alone should recommend it to the engineer and to the estimating office equally.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

MOTOR LOAD FACTOR v. STATION LOAD FACTOR.

SIR,—There seems to be a delightful variety of ideas among our station engineers on the subject of tariffs. On the one hand, we find them giving discounts in direct proportion to the load factor of the individual consumer's motor, thus in great measure neglecting the station load factor, and, on the other hand, we have the Dundee system of charging, which practically bases everything upon the station load factor. I submit that neither of these is right. I will, with your permission, Mr. Editor, try to formulate a simple hypothetical case to illustrate the various relations of motor load factor, diversity factor, station load factor ("Cromptonian" sense), and standing charges.

Consider (1) a station which supplies 24 motors, each fully loaded throughout the 24 hours. Let the motors be of, say, 100 h.p. each. The station load factor is here 100 per cent., the motor load factor 100 per cent, and the diversity factor unity. Next consider (2) a smaller station supplying the same 24 motors, but in the following way: Each motors only runs for one hour, one motor being shut down before the next is started up. Here the motor load is $4\frac{1}{6}$ per cent. instead of 100 per cent.; the diversity factor is 24·0 and the station load factor is 100 per cent. The station capacity is, however, now only 100 h.p.; so, to put things on all fours as far as the two stations are concerned, let the number of motors (*i.e.*, consumers) be increased 24 times. We may then express results as follows:

	Case 1.	Case 2.
Number of motors	24	576
Horse-power of each	100	100
Units sold per consumer per annum, say	200,000	8,333, say
Diversity factor	1	24
Motor load factor	100 per cent.	$4\frac{1}{6}$ per cent. ($=\frac{1}{24}$)
Station load factor	100 per cent.	100 per cent.
Station horse-power	2,400	2,400
Total units sold per annum, say	4,800,000	4,800,000
Total horse-power connected to mains	2,400	57,600

Now consider the annual charges, and, for the sake of fixing proportions, take figures roughly, as for Brighton in 1900, and we have, say:

	Case 1.	Case 2.
Interest, etc., charges on central station	£10,000	£10,000
,, ,, ,, ,, feeders, mains, and service connections	10,000	say 50,000
Management charges	1,500	say 2,000
Clerical staff	1,200	say 28,800
Rates, taxes, and insurance	1,200	say 2,400
Motor readings and repairs	1,000	say 24,000
Repairs to mains and service connections	1,500	say 7,500
Net profit	5,000	say 5,000
	£31,400	£128,700
Add:		
Production costs at station	9,000	9,000
Preparation costs at station (ex. management, etc.)	10,000	10,000
	£50,400	£148,700

Some engineers who maintain that each consumer should pay an equal profit would put the item for net profit in Case 2 at £120,000, but, to spare the feelings of those who object to such a course, we will assume that it is a constant sum. The totals, it will be seen, are in the ratio of 1 to 3, and, as the total number of units sold in each case is the same, it follows that the average prices per unit must be fixed also in that ratio.

Of course, it will be objected that the case is a purely imaginary and greatly exaggerated one; but it shows that motor load factor and station load factor must each be used with judgment, the one to determine charges outside the station and the other those inside it. In actual practice it will be found that station load factor *diminishes* with a decreasing motor load factor, *even though the motor connections be increased in the inverse ratio*, as I have shown elsewhere. This would aggravate the cost per unit in Case 2.—Yours, etc.,

A. M. TAYLOR.

11, Ashfield-road, King's Heath,
July 10, 1905.

LIVERPOOL UNIVERSITY AND ELECTROTECHNICS.

Opening of a New Laboratory.

Last Saturday, July 8, being degree day at Liverpool University, the opportunity was taken by the council and senate to include in the day's programme the important function of formally opening the new laboratory of electrotechnics. The ceremony of conferring the degrees took place early in the afternoon in St. George's Hall, and was performed by the chancellor of the university, the Right Hon. the Earl of Derby, K.G., G.C.B., LL.D.

The opening of the new laboratory followed. Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S., now addressed the assemblage in reference to this important part of the day's proceedings. Reverting to 1880, Sir Joseph spoke of the immense strides which electrical engineering had made in the 25 years which had passed since then, and of how the profession of the electrical engineer as it stands to-day had come into existence. Electrical engineers, he pointed out, now formed a distinct class, which was represented by the organisation formed by more than 5,000 members of the Institution of Electrical Engineers, and outside of which there was a ten times larger body of organised and skilled artisans on which they made calls. Electrical engineering was, in fact, the most popular branch of a most popular profession, and undoubtedly was a pursuit which would be cultivated, and which must be cultivated if they were to maintain their position. The electrical engineer had now attained the distinction of being an absolutely indispensable person. Electricity was even yet in its infancy—an idea made still more impressive by the fact that this representative body of young men had to make productive an amount of capital which Mr. Gareke, who was an authority on the point, estimated at £230,000,000 sterling. Yet for want of a little more spirit coupled with knowledge, and painstaking to apply it judiciously, we had lost to our friends abroad some of the lead which we had had. There were many signs of rapidly increasing industry and changes, and it was well that Liverpool was preparing to participate in whatever advantages they might bring. Through the enterprise of Mr. Bromley-Holmes, they had for many years been familiar with the electric light in Liverpool, and Liverpool had been one of the first places in the kingdom to possess a fully equipped electric railway. More recently they had had electricity applied with great success and on a large scale in the street locomotive, so they were well acquainted with electrical progress, and were aware of its importance. He might almost say Liverpool had lived in the atmosphere of electricity. Sir Joseph Wilson Swan brought his address to a close by referring to the new laboratory, and expressing the hope that it might not only be of use to the students, but to the university itself and to the world. A Davy or a Faraday was, he said, a rare product, but there was nothing unreasonable in the assumption that other names might be identified with the new laboratory of Liverpool.

The proceedings in the hall now closed, but a large proportion of the audience went at once to the new laboratory. On reassembling in the lecture theatre, Sir Joseph Wilson Swan again addressed the gathering. He thought they might all unite, he said, in a general note of congratulation on the opening of that laboratory. Laboratories were often very small and inconvenient places; that place was both large and convenient. Sir Joseph proceeded to speak in some detail of the laboratory and of its need of equipment, and brought his remarks to a close by expressing the earnest hope that prosperity would attend it and those who worked in it.

With the opening of the new laboratory the teaching of electrotechnics at Liverpool entered on a new era, under conditions worthy of the city and of the branch of science to be taught and practised. Electrotechnics have formed a branch of study at Liverpool University for the last 12 years, but for the first seven of these years they were a branch of the physics department, and were controlled by the professor of physics. The work of the branch was carried on in temporary sheds, which stood at the back of the building which originally served as Liverpool's University College. In the year 1900 a lectureship of

Digitized by Google

electrotechnics was established, and this branch of study was made a separate department of the college. Dr. E. W. Marchant, D.Sc., was appointed to the new lectureship. Meantime, steps were being taken to raise University College, Liverpool, to the status of a fully dignified university, and funds for the purpose were being contributed. One donor (Mr. David Jardine, of Liverpool) gave the sum of £10,000 to the funds, and expressed the wish that the money should be used to endow a chair of electrotechnics In accordance with this wish a chair was established, and Dr. Marchant, who had then been lecturer on electrotechnics for the university for about two years, was appointed to the professorship. Matters having reached this stage it became desirable that a suitable domicile for the newly-formed department should be found, and it was decided to erect an adequate building as a laboratory of electrotechnics. A site was obtained in Brownlow-street, adjoining the new building of the natural history and botanical laboratory which had been presented to the university by Mr. W. P. Hartley, of Liverpool. Designs were prepared by Messrs. Willink and Thicknesse, architects, and shortly after the erection of the building began, Messrs. William Thornton and Sons, of Liverpool, being the contractors. The sum of £12,000 was provided from the university fund to cover the cost of the building, and £1,000 was contributed by the Lancashire County Council towards the equipment. The building was designed for utility. The elevation which fronts to Brownlow-street shows a structure of four storeys and a basement in a substantial though plain modern style and with a liberal provision of windows, the building serving well as a completing wing to the natural history and botanical laboratory. The basement of this earlier building has been secured for use by the electrotechnics department, and, for the time, the two upper storeys of the new building will be used for other work.

Arrangements and Apparatus.

The basement of the new building, together, as aforesaid, with the basement of the natural history and botanical laboratory and the ground floor and first floor of the new building, will for the present be used for the purposes of the electrotechnical department. The dynamo-room, a standard testing room, a museum, rooms for special testing and experimenting work, and photometric and photographic dark rooms are in the basement. Dr. Marchant's private office and private laboratory, a galvanometer room, and rooms for senior students' experimental and test work are situated on the ground floor. The lecture theatre, classrooms, a reading-room and library, and rooms furnished with apparatus for pursuing investigations along special lines of electrotechnology, are situated on the first floor.

In the basement, the dynamo-room claims first attention. It is trapezoidal in form and averages 60ft. by 56ft. Two-thirds of the room form an extension of the main building, and have a glass roof. The walls are faced with white glazed bricks. The interior is accordingly very light and cheerful. The floor is of concrete, and on it have been built four rows of brick beds some 16in. high for the motors and dynamos. Near one corner of the room, on a separate brick bed, stands the principal power set. This consists of a two-cylinder Westinghouse inverted vertical gas-engine of 40 h.p., with enclosed cranks and rods, coupled direct with a Westinghouse standard direct-current four-pole generator. The capacity is 22½ kw. at 230 volts, the stated speed being 300 revolutions. This generator will produce current for lighting the entire building, and will also be used to charge accumulators, and for demonstrating purposes. A Schuckert electric tramcar truck stands in line with the engine and dynamo, a few feet distant from this main power set. The truck was presented to the laboratory by the Corporation of Liverpool. Wood supports have been used to raise the truck so as to allow of the motors and wheels being worked. The truck has two Schuckert motors of 25 h.p. each, and a Schuckert controller, and is fully wired for use. The connections between the controller and the motors have been made by the students.

A number of motors and dynamos are now in the room, some of them having been lent by firms for experimental work and testing. Among the machines are a Fuller and Wenstrom three-phase generator with 10 poles and rotating armature; a rotary converter by the same makers, capable of producing single, double, or three-phase current, stated as of 460 volts and 22 amperes, to run at 1,500 revolutions; a Johnson-Phillips dynamo with special winding; a continuous-current generator, by Siemens Bros., of 55 volts and 85 amperes, to run at 960 revolutions; two single-phase generators by Witting and Eborall; a two-phase motor-generator by the same makers; a Heyland single-phase motor and motors or dynamos by the Lancashire Dynamo and Motor Co., Crompton and Co., and J. H. Holmes and Co. Each of the beds on which the machines stand is provided with two pairs of foundation rails, so fixed that machines can be easily secured to the rails or be removed from them for experimenting or demonstrating All of the dynamos are driven by motors which receive current from the Corporation mains, the driving being at present done by belt to and from two main shafts. This method of driving will, however, give place to direct driving by motors. The wires from the Corporation mains are fixed overhead in the room, and are carried down in open view to the motors. The wires between the switchboards and the experimental machinery have been laid in troughs below the floor.

With regard to the provision for lighting the building, this is such as to admit of current being taken from the Corporation main or from the gas-engine generator. It is intended that the lighting system of the building shall serve an important purpose in connection with the work of the students. The system will be used as a "load" to be varied and studied as occasion may require, connections being provided which will admit of the load being so varied.

Two switchboards have been placed in the dynamo-room. One of these is used mainly to control the lights of the building. This board consists of two panels of slate enamelled black, and is fitted with three continuous-current meters of the International Electric Company's pattern, and with a massive change-over switch by the use of which the supply of current can be taken from the city main or from the generator. The other switchboard is larger than the lighting board, and has been designed and fitted to enable the students to make the connections required in the course of their studies in the dynamo-room. This board has four panels, the face being of very light-grey marble. Each panel is provided with a number of short screw-plug terminals. From the back of the board, wires attached to the plugs communicate with the different class-rooms and research rooms. At the front of the board the terminals project about 3in., each one being fitted with a screw plug. No switches of any kind appear on this board, the intention being that switching or changing over shall be done by the students, and by the use of the screw plugs and the terminals on the wires. By this means any of the experimental machines may be put in communication with any classroom, and the character of the current or particular effects be studied in the classrooms. All of the plugs in front of the board, and the leads from the plugs at the back of the board, are open to view, the intention as regards this board being that "there shall be nothing which the student cannot see." Ample space has been left between the board and the wall of the room to admit of the connections being seen with ease.

Adjoining the dynamo-room is a spacious workshop, which is well supplied with modern tools. Among these are two lathes, a drill, and a planing machine, which are belt-driven by a B.T.H. motor of 2 h.p. In order to transmit power from the motor, and to avoid the transmission of vibration to other parts of the building, a frame of light girder steel, consisting of uprights and cross-pieces, was erected, the uprights resting on the rock foundation, and the small main shaft being supported by the steel structure. This has given the shaft a support completely independent of wall or ceiling, and seems well suited to ensure freedom for the walls and the floor above from vibration through the working of the machine tools. Repairs and alterations to apparatus will be done in the workshop. It is expected that a considerable use will be made of the workshop by senior students in constructing apparatus for special work.

Digitized by Google

A well-lighted apartment in the basement has been fitted up as a museum, and will, it is believed, prove of great service. Here are arranged specimens of materials used in the construction of electrical apparatus, specimens of telegraph, telephone, and supply cables, motor parts, insulating materials, electric lamps' parts, filaments, and photographs of electrical installations of particular interest. A senior students' laboratory, 34ft. by 28ft., is located near the dynamo-room. Transformer and alternating-current work will be carried on largely in this room. Here, two three-phase static core transformers of Witting and Eborall's pattern, a synchronous motor of Mather and Platt's construction, and other small machines, have been installed.

A room 35ft. by 13ft. has been set apart as a "high-tension" room, in which high-pressure currents and effects can be studied. For the purpose a 20,000-volt oil-cooled transformer, of Witting and Eborall's construction, has been installed. Current for this instrument will be obtained from the dynamo-room. Insulating materials will be subjected to "breakdown" tests, and the action of the materials under varying pressures will be studied. In the basement there is also a room in which the testing of iron and steel for magnetic properties and electrical conductivity will be carried out. Work of this kind will be done for firms outside, and reports as to the results be supplied to them. This room is provided with galvanometers, permeameters, and other instruments for performing such tests.

There are still some eight other rooms in the basement which will be used for particular branches of electrotechnical study. One of these rooms will be devoted to the study and testing of electric lamps, more particularly with a view to comparing the duration of life of different lamps. A special lampholder, in the form of a circular drum which can be revolved horizontally, has been constructed, and a switching arrangement has been made by which the current taken up by each lamp can be measured without breaking the circuit. A piece of apparatus has been constructed by the use of which the electrical pressure may be maintained automatically on lamps, at a constancy to within one part in four hundred. This is accomplished by varying the field of the generator. The generator is driven at a constant speed by a motor which receives its current from the accumulator. The regulating device consists of a dynamometer having a pointer attached to a moving system of light construction, the free period of the instrument being 1½ seconds. The pointer actuates a relay which closes the circuit of a motor attached to a movable resistance in the field of the generator. The object is to vary the frequency as rapidly as possible. This is accomplished by having a dynamometer with a quick period. The actual changes are but slow, and can be well followed, so that the whole variation in the lamp does not exceed one part in four hundred at any time. By means of this apparatus lamps can be tested under definite conditions as regards voltage. Variations in efficiency are determined by photometric tests. Lamps are tested under ordinary conditions—subject, that is to say, to the variations in pressure on the town mains. Another room is fitted for photometric work and with instruments to measure the efficiency of electric lamps and the amount of energy consumed. A room 39ft. by 35ft. has been set apart for standard instruments, which will be compared periodically with the standards at the National Physical Laboratory that accuracy may be maintained. A small battery of some 20 cells will be provided for use in standardising. Two other rooms, each 27ft. by 20ft., have been set apart for research. One of these rooms is provided with a high-frequency Duddell oscillograph for ascertaining losses occurring in dynamos and motors, especially in pole-pieces. Eddy currents will be a subject of special study. One room will be used as a test-room for meters. Many tests of this kind have been made by the department in the past. The energy required for these rooms will be controlled by a special switchboard in the meter-testing room. The board is connected with the main board, and can be connected with dynamos or cells or with any part of the building. The cables from the board to the dynamo-room lie in a trough filled in with bitumen, which passes below the surface of an outer quadrangle.

On the ground floor the galvanometer room claims, perhaps, first attention. Among the instruments in this room are three ballistic galvanometers, two of Crompton and Midgett's and one of Nasmyth and Mather's construction. Most of the work will, however, be done by galvanometers of a kind made at the laboratory. With these a spot of light is used to give the reading on the scale. The chief parts of the instrument are: a strip of celluloid on which the scale appears and which is fixed edgewise; below this scale is a small cylinder which contains a Nernst lamp; some 4ft. from the lamp there is another cylinder in which a small mirror is fixed. The light of the lamp is projected on the mirror and is reflected by the mirror on the back of the celluloid scale. The observer stands in front of the scale. Owing to the transparency of the celluloid, the spot of light shows distinctly through the scale. The movements of the needle can be observed by the spot of light even in daylight owing to the power of the Nernst lamp. Eight of these galvanometers are now in use. For special measurements and Wheatstone bridge work a galvanometer of Nalder Bros. and Thompson's make will be used.

A junior laboratory on this floor possesses an item of equipment worthy of note. This is a switchboard, with a face of light-grey marble, which is fitted in a manner similar to that of the experimental board in the dynamo-room, a number of screw-plug terminals appearing on the face of the board. When using this board, as in the case of the larger main board, students will have to make all desired connections by means of the screw terminals. No switches of the ordinary handle or lever types are provided. The board is connected with the main battery, which is in an adjoining room. The battery contains four sets of 10 cells each and two of nine each, there being Tudor, Chloride, and Electrical Power Storage Companies' cells. A pressure of 120 volts can be obtained from the cells. At the switchboard the cells may be connected in series or parallel, and may be connected with different rooms.

The lecture theatre of the laboratory is on the first floor. It is a cheerful room, with modern appointments, and will seat 130 people, and is provided with a lantern, screen, large blackboard, specially constructed demonstrator's table, and means of connecting instruments in use on the table with the dynamo-room, the main battery, and other rooms of the building. A connection may be made with any machine in the dynamo-room, so that a demonstration into which the individuality of the machine may enter may be given in sight of the students. Another room in this floor is provided with a valuable piece of apparatus in the form of a Duddell oscillograph, which will be used chiefly for showing the wave variations of alternating currents. Here, again, terminal connections have been provided by which current can be brought from any dynamo in the machine-room, and be made the subject of observation by the demonstrator and the students.

As the work of the department adjusts itself and develops, rearrangements of rooms and apparatus will no doubt be made. The facts which stand out most strikingly are that the present arrangements afford the use of many valuable modern machines and instruments, and special facilities in the form of connecting wires, by which the output of the generating machines may be available and the behaviour of the machines be studied in the lecture theatre and the classrooms. The electrical fittings of the laboratory, it may be mentioned, were supplied by Messrs. John Hunter and Co., of Liverpool.

THE MUNICIPAL TRAMWAYS ASSOCIATION.

Visit to Reading and Henley.

On Thursday, July 6, through the kind invitation of Mr. Councillor A. H. Bull, J.P., chairman of the Reading Corporation Tramways Committee, the members of the Municipal Tramways Association attending the conference in London journeyed to Reading by special train, leaving Paddington at 11 o'clock and arriving at Reading at 11.45.

Digitized by Google

The members, who were accompanied by a large number of ladies, were received at the station by Mr. Walter Binns, general manager and engineer of the Reading Corporation tramways. The party were conducted to the town hall, which was tastefully decorated for the occasion, and at noon the party were received by the Mayor of Reading (Martin J. Sutton, Esq., J.P.) and Mr. Councillor A. H. Bull, J.P., and Mrs. Bull, in the Council-chamber, and the mayor formally welcomed the association to the ancient borough, expressing his gratification at the privilege of receiving the members of the association. Subsequently the party adjourned to the large town hall, where a first-class luncheon was provided through the kindness of Mr. Bull. The tables were magnificently decorated, and during the assembling of the guests and the luncheon the organist discoursed sweet music on the fine organ in the hall, which was highly appreciated by the guests, some of the pieces being encored. An interesting souvenir of the occasion was prepared by Mr. Binns, giving the names of the principal officers of the borough and members of the Tramways Committee, the menu and toast list, and a brief sketch of the tramway system and places of historic interest in connection with the ancient borough. The description of the beauties of the Thames from Caversham to Henley, and the chief points of interest seen from the river, was instructive and much appreciated by the guests, and will no doubt be retained by them as a pleasant reminder of what proved to be a most delightful excursion. A short toast list was gone through at the close of the luncheon, and the party then walked through the Forbury Gardens, where the flower beds were most beautifully laid out, to the ruins of the old abbey, where the whole of the party were photographed. The steam launch "England," the largest launch on the Thames, was requisitioned by Mr. Bull, and the party embarked at Caversham Lock and proceeded down the Thames to Henley, tea being served on board during the trip. On reaching Marsh Lock, Mr. C. R. Bellamy, of Liverpool, took the opportunity of expressing to Mr. Walter Binns, on behalf of the president and members of the association, their best thanks and appreciation of the admirable arrangements which had been made for their comfort and pleasure, and which had been so ably carried out, and assured him that they would long remember their visit to Reading, which had been so very enjoyable. Mr. Walter Binns in a few words acknowledged the vote of thanks, and stated that it had been a great pleasure to him to see the members of the association at Reading, and that what he had been privileged to do in making the arrangements for their visit had also been a very great pleasure. He also referred to the great kindness of Mr. Councillor Bull, who had so generously entertained the association, and who had spared no pains nor expense to make their visit an exceedingly happy and memorable one. The launch then proceeded towards Henley, and moored some little distance above Henley Bridge. Through the kindness of the Mayor of Reading members were permitted to go on to the lawns at Phyllis Court, for a nominal sum, from which a splendid view could be had of the regatta and, later in the evening, the fireworks, the lawns being opposite to the winning post. Concerts were given during the evening in the grounds. Members returned to London later in the evening, and all who took part in the day's proceedings will retain a pleasant recollection of the occasion for many years to come.

THE ADMINISTRATIVE COUNTY OF LONDON AND DISTRICT ELECTRIC POWER BILL.

Yesterday morning in the Westminster Hall this measure came on for consideration by a Select Committee of the House of Commons, consisting of Sir James Kitson (chairman), Sir Herbert E. Maxwell, Mr. Frank Edwards, and Mr. Rutherford.

The promoters were represented by Mr. J. D. Fitzgerald, K.C., Mr. Honoratus Lloyd, K.C., Mr. Charteris, Mr. Macassey, and Mr. Thomas Richardson. The Bill was opposed by the City Corporation, the London County Council, some of the borough councils, the Westminster City Council, the East and West Ham Corporations, some of the local authorities in the outlying districts, and several electrical, gas, and other companies. Mr. Balfour-Browne, K.C., Mr. Freeman, K.C., Lord Robert Cecil, Mr. Courthope Munroe, and Mr. Vesey Knox were among the counsel for the opponents to the Bill.

Mr. FITZGERALD, in outlining the Bill, gave a statement of the promoters' scheme, this necessarily being on much the same lines as those followed before the Lords' Committee. He stated it was proposed to establish three large generating stations on the banks of the Thames, where they, unlike the existing companies, would be conveniently situated for a supply of cheap seaborne coal and water for condensing. In regard to the plaint of the opponents respecting unfair competition, he mentioned that last year the existing undertakers only derived 8 per cent. of their income from the supply of power. Of the 456,000 h.p. used in the Metropolis for industrial purposes, the quantity of electrical energy so employed represents no more than 16,000 h.p. He reiterated the points made before the Lords' Committee regarding the economy in generation, saving of capital expenditure to individual concerns, and the facilities afforded to industries generally by a supply of cheap power, and instanced the case of the Tyneside Electrical Company, which in a large measure has supplanted steam. Further, the Lords' Committee had inserted additional protective clauses in favour of the existing companies beyond the usual clauses originally included in the Bill. As some of the opponents of the Bill had objected that the promoters might extend by specious methods the limited lighting powers asked for, the promoters had agreed that in no case should more than 20 per cent. of the energy supplied be used for illumination. New provisions inserted in the Bill as the result of the hearing before the Lords' Committee provided that where the promoters obtained leave to supply power in the same districts as the authorised undertakers, they shall do so under the same conditions as the latter; and that the Board of Trade shall have power to impose regulations upon the promoters regarding the compulsory laying of mains. Since the measure was before the Lords' Committee, the Stepney Borough Council, one of the most successful municipal electric light undertakers in the Metropolis, had provisionally agreed to take all energy which their present works could not generate on schedule rates expected to average 66d. per unit. The Council agree to supply power consumers at an average charge of 8d. per unit, at against the present charge of 1d. per unit. This would save contemplated extensions which were expected to cost £250,000. The Barking Council was prepared to transfer its undertaking to the company, and the Bexley Urban District Council had also come to an understanding with the promoters respecting the supply of energy, which was expected to result in current being provided to the consumer at reductions of 30 and 40 per cent. respectively upon those now ruling. The Wandsworth Borough Council have petitioned against the Bill on the grounds that they were not included in the industrial areas, as they should be. This showed that the Council appreciated the advantages of the Bill. It should be noticed that all the supply companies at present at work had their power stations either within the industrial area or outside the area of the Bill. He held that there would be no competition in the non-industrial area. The London County Council had called no witnesses before the Lords' Committee, and their chief objection appeared to be that there was no purchase clause. This was the case in all Power Bills, and the sliding scale was introduced in them to replace this clause. The company were willing, however, to introduce such a clause, and left it to the committee to settle now the wording of the same, and a reasonable period before it should become operative. In conclusion, he stated that the Bill was an effort on the part of a number of gentlemen in combination to give a cheap supply of electric power where it was most needed.

Mr. C. H. MERZ, under examination, repeated a great deal of the evidence given before the Lords' Committee as to the advantages of electrical power distribution. He dwelt at length upon the adaptability of electric motors for factory driving, and upon the low cost of repairs, as compared with isolated steam-engines. The Tyneside

Digitized by Google

scheme had proved this to be the case, and it was most difficult for power distribution to succeed in areas where coal was cheap. Hence the London scheme would have an advantage in this respect. The coal required for electric power distribution was less than 2lb. per horse-power-hour, as against between 5lb. and 7lb. with small steam plants. The reason why certain of the Power Acts had not been put into force was because the promoters had given away too much in clauses. A number of tables were then put in as evidence and described in detail to show the probable power consumption within the area. The tables as to cost of supply were generally the same as those given before the Lords' Committee. The financial statistics relating to the existing lighting authorities were new, and were based on the evidence given by the opponents of the Bill in the House of Lords. The average expenditure on existing generating stations was given as £50·5, the works' cost per unit generated 0·98d., the total works' cost, including capital charges, 1·78d. Only 7·4 per cent. of the revenue now obtained was for the supply of power. The average size of the 419 engines now installed in the 51 stations was 331 kw. The average price obtained for power by the existing undertakers was 1·949d. per unit. There were special cases where a lower price was charged, and this was frequently below the cost price. The deficit was then made up out of the lighting or tramway charges. It was unfair to compare special charges to individual consumers with the average charge proposed under the Bill. The hire of motors and the giving of expert advice to intending consumers was essential to the success of a power scheme, and had conduced to the spread of the Tyneside undertaking. In certain cases guarantees were given as to the reduction in cost which would result from the change over to electric driving.

The committee adjourned until 11.30 this morning, when the examination of Mr. Merz will be continued.

PERSONAL.

The Corporation of Western Egypt have appointed as its general manager in Egypt Mr. W. C. Beckett, M.I.C.E., until now chief engineer of the Bengal-Nagpur Railway.

Mr. Joseph Dugdale has been appointed tramway manager to the Aston Corporation, rendered vacant by the retirement of Mr. A. Coveney, who has been appointed tramway manager at Erith.

The salary of the electrical engineer at Dover (Mr. L. W. Woodman) has been increased from £350 to £425 per annum, as from Jan. 1 last.

F. Scarr, of Melton Mowbray, has been engaged as switchboard attendant and driver at Loughborough at 25s. per week.

Mr. Robert Foster has been appointed resident electrical engineer at Aston at a salary of £300 per annum, the appointment to take effect as from Jan. 1, 1905.

We understand that the salary of Mr. D. Smith, the assistant electrical engineer of Tunbridge Wells, has been increased by £25.

The salary of Mr. R. E. Meade, electrician in the electrical department, Stafford Town Council, has been increased from £150 to £175 per annum.

FORTHCOMING EVENTS.

Permanent-Way Institution. — Summer convention begins on July 21, continuing till July 27, in the course of which a visit will be paid to Holland.

New Publications.—We have received the tenth edition, twenty-third to twenty-seventh thousand, which is considerably enlarged and well supplied with numerous diagrams and formulæ, of a text-book on practical physics by Friedrich Kohlrausch. The book is published, as its predecessors, by G. B. Teubner, Leipsic and Berlin. The formulæ are mainly arranged upon the proposals made by the German Physical Society, but in some cases the author has endeavoured to expunge inconsequences and to amalgamate differences so that as much as possible the same letter is used to denote the same constants. The *Physical Review* (New York) dated June contains Chapter II. of an article on "Infra-red Absorption Spectra," by W. W. Coblentz; "The Electric Arc in a Vacuum," by C. D. Child; and minutes of the proceedings at the twenty-eighth meeting of the American Physical Society.

TRADE NOTICES AND NOVELTIES.

Arc Lamp Lowering Gear.

The London Electrical Firm, of George-street, Croydon, have recently introduced an improved contact and suspension device for arc lamps, and also a self-sustaining winch which can be used in connection with the same. Both of these are illustrated herewith. The contact device, shown in Fig. 1, is exceedingly simple in its action.

FIG. 1.

The actual contacts are made between the two spring rings of the piston-ring type, which can be seen in the illustration, and two similar rings, which are contained in the fixed socket. The pin seen at the top of the plunger is used to take the weight of the lamp when in position. This pin engages in grooves, which are constructed on the inside of the socket in sufficient numbers to prevent there being any necessity for the plunger to have a definite angular position with respect to the socket. The shapes of the grooves are such that the pin engages irrespective of the angular position of the plunger. In order to lower the lamp, it has first to be raised slightly higher, and this carries the pin to points in the grooves at which free passages for lowering are obtained. This contact device looks somewhat bulky in the illustrations, but it is only 8¼in. long and 7in. in

FIG. 2.

diameter. The winch illustrated in Fig. 2 is a most interesting piece of apparatus, which we cannot describe in detail owing to the patents being uncompleted. The great feature of the winch is a new mechanical movement which gives a reduction of 4 to 1 between the handle and the drum containing the wire rope. For this movement no pawls or gear wheels are required, and yet the drum will sustain the weight of the arc lamp in any position. The winch for holding 40ft. of $\frac{3}{16}$in. wire rope or 20ft. of ¼in. rope is only 5¼in. diameter by 3¼in. deep. This will come into any ordinary arc lamp column, but the winch can also be fixed on the outside of the poles if desired. With this combination of winch and contact device, street arc lamps can be trimmed much more expeditiously than by means of a tower wagon, which involves heavy labour charges for transport.

APPOINTMENTS VACANT.

Borough Electrical Engineer, Cheltenham. Salary, £400 per annum. Applications by 18th inst. See advertisement in last issue.

Borough Electrical Engineer, West Bromwich. Salary, £300 per annum. Applications by July 17.

Lecturer on Electrical Engineering, Hull municipal technical school. Salary, £200 per annum. Applications, on forms, to J. T. Riley, D.Sc., director of studies, by 15th inst. See advertisement in last issue.

Electrical Engineer as manager to lighting and power contractors. See advertisement in last issue.

Assistant Electrical Engineer, Acton Urban District Council. Salary, £130 per annum. Applications by 12 noon on July 18. See advertisement.

Electric Light Canvasser, Limerick Corporation; £100 per annum.

LEGAL INTELLIGENCE.

BIDEFORD AND APPLEDORE RAILWAY.

In the King's Bench Division on Monday the hearing of the action of the British Electric Traction Co. against Charles Chadwell, the contractor of the Bideford and Appledore Light Railway, in which the plaintiffs claim £8,000 for non-completion of works, was commenced.

Mr. JERVIS, the engineer of the railway, said he often remonstrated with defendant on the dilatory way the work went on. He replied that he was not getting his payments regularly, and that the local authorities threatened an injunction if he proceeded, and he also complained of the manner in which he had been dealt with in connection with his Devonport District Tramways contract.

After hearing further evidence the hearing was adjourned.

QUESTION OF FARES.

Before Lords Justices Romer and Mathew, in the Court of Appeal, on Monday, Mr. Roskill, K.C., applied on behalf of the defendants in the case of Ramsay *v.* the London United Tramways (1901) for a stay of execution pending an appeal from verdict and judgment before Mr. Justice Bucknill and a jury. The plaintiff's case was that for failing to pay his tramway fare of one penny he was taken into custody, as he said, by the direction of the tramway company, which was denied by the company. The plaintiff was charged by the police with using obscene language, and also by the tramway company with non-payment of the fare. At the trial a verdict was returned for the plaintiff for one farthing damages for the alleged false imprisonment and £20 damages for the alleged malicious prosecution. Their Lordships granted the stay on defendants paying £20 into court and paying the plaintiff's solicitors the taxed costs on the usual undertaking to return them if the company's appeal proved successful.

GARCIN RENAULT ELECTRIC CARS AND ACCUMULATORS.

The creditors and shareholders of this Company met at the Carey-street office of the Board of Trade, Lincoln's-inn, W.C., on Tuesday, when Mr. Winearls (assistant-receiver) reported that an approximate statement had been lodged under the liquidation, showing total liabilities £3,284, a deficiency of £2,703 in assets to meet the liabilities, and a total deficiency of £2,773 to the contributories. In the absence of a quorum, the matter was formally adjourned for a week, when, if no resolution is passed, the liquidation will remain in the hands of the official receiver.

COMPANIES' MEETINGS AND REPORTS

EDMUNDSON'S ELECTRICITY.

The eighth ordinary general meeting of this Company was held last week at the Westminster Palace Hotel, Victoria-street, S.W., Mr. Francis E. Gripper, M.I.E.E. (chairman and managing director of the Company), presiding. Particulars of the report for the year appeared in our issue of the 30th ult.

The CHAIRMAN, after reviewing the position generally, stated that the total investments in subsidiary companies, taken at par value, amounted to £1,253,789. The reserve against those investments had increased during the last year by £7,320, making a total of £172,705. 8s. 2d. This increase of reserve was much smaller than for the previous year, when a very large amount was added to reserve. The value of these investments was increasing from year to year, and the directors anticipated that it would not be necessary to continue to add to this reserve to so great an extent; in fact, they hoped that a considerable portion of the reserve that had been set aside in this manner would so increase in value that it may properly be taken at par value, and thus increase the profits during the next few years. He concluded by formally moving: "That the eighth annual report and statement of accounts for the year ended March 31, 1905, be, and are hereby, adopted, and that, as recommended therein, a final dividend at the rate of 9 per cent. per annum for the half-year be paid on the 70 000 old ordinary shares, making 7 per cent. for the year, and that a dividend at the rate of 7 per cent. per annum be paid on the 10,000 new ordinary shares."

The resolution was carried unanimously.

Mr. J. W. Edmundson was re-elected a director.

NEW GENERAL TRACTION.

The ninth annual general meeting of the New General Electric Traction Co. was held at the offices last week, Baron Emile B. d'Erlanger presiding.

The CHAIRMAN said that they would see that the policy of the Board of reducing expenses as much as possible had been pursued in the past year, and that the general expenses, which amounted to £3,272 in 1904 and then already showed a reduction on the year 1903 of some 20 per cent., had been reduced to £2,536, showing a further reduction of £686—practically a further 20 per cent.—so that in two years the general expenses had been cut down about 40 per cent. The amounts received in dividends from sub-companies showed an increase over the year 1904 of £2,675, and of £3,724 over the year 1903. The Philadelphia system was now completed, and they had received the whole of the securities to which they were entitled—*i.e.*, £170,000 bonds and £139,000 shares—and they would be creditors, besides, for the sum of £5,000, the Traction Co. having acted towards the subsidiary company in the capacity of a car trust company, receiving repayment by instalments. The Marborough Act had since the date of this balance-sheet been disposed of for the sum of £2,500, and the Company had been relieved of heavy contingent liabilities. The amount of cash in hand was £6,326, and the net result of the year had been a loss of £6,855, after paying all the interest on debentures and loans, which really was a loss of only £4,644, as, to compare with the previous year, they ought to have given themselves credit for £2,211, representing the dividend from Coventry. The Chairman said he thought they had now reached the minimum expense at which the business of the Company could be effectively carried on. Last year they estimated the fixed charges of the Company at £16,900; but to that must be added another £1,000 for interest on, in round figures, £20,000 of 5 per cent. mortgage debentures, so that the fixed charges were really £17,900. without taking into consideration any sinking fund for the debentures. Against these fixed charges of £17,900 they had this year a net income from the sub-companies of £12,089. For the year 1904 the Philadelphia tramways showed a net profit of £3,667; this year the gross receipts have shown a good expansion. The receipts up to June 18, 1904, amounted to £6 037; the receipts to June 18 this year amounted to £7,632. For the first half-year he was afraid that little of the increased gross represented net increase, because the 40 odd snowstorms in the city of Philadelphia during the winter had naturally entailed a considerable increase in the operating expenses. He had every reason to believe that during the summer they would reap the benefit of the increase in the gross receipts, which was satisfactory. The Norwich company was more or less *in statu quo*. The Eastern Counties had not shown any signs of increasing activity and returning prosperity, and the receipts of the tramways in Norwich were, consequently, affected by the bad times from which that important city was suffering, though a 3 per cent. dividend was paid for the year 1903-1904, against 2½ per cent. for the preceding year. Coming to the Coventry tramways, the Chairman stated the year 1904 showed a decrease of £1,232 in the net; but that decrease was entirely owing to the loss of earnings consequent upon the disorganisation of the traffic, caused by the relaying of the old lines and the construction of the extensions. That work had now been concluded, and so far the traffics were of a very promising nature. They would now understand that, after a few deferred payments that had to be made, both in respect of Philadelphia and Coventry, the era of large capital expenditure had been definitely closed, and the New General Traction Co. would depend entirely upon the revenues derived from its subsidiary companies.

The report was unanimously adopted, and the Hon. A. G. Brand, M.P., re-elected a director.

MARCONI'S WIRELESS TELEGRAPH.

An extraordinary general meeting was held on Tuesday at the offices, 18, Finch-lane, E.C., for the purpose of passing resolutions altering the articles of association in which was provided a clause having for its object the increasing of the Company's capital to £500,000 by the creation of 200,000 further shares of £1 each.

Mr. CUTHBERT HALL, who presided, formally moved the adoption of the resolutions. In doing so he observed that certain of the resolutions were brought forward in order to meet the wishes of the shareholders, who were desirous of seeing the shares of the Company quoted in the Stock Exchange official list. The resolution having reference to the increase of capital was considered necessary in view of expansion of the business, but any new issue of shares that might be deemed desirable would, in the first instance, be issued to the shareholders.

Major FLOOD PAGE seconded the resolutions, which were carried unanimously.

EASTERN TELEGRAPH.

The Eastern Telegraph Co. announce that, subject to final audit, the accounts show, after payment of interest on the 4 per cent. mortgage debenture stock, the dividend on the 3½ per cent. preference stock to March 31, and an interim dividend of £1. 5s. per cent. on the ordinary stock to Dec. 31 last, a balance available sufficient to pay a final dividend of £1. 5s. per cent. and a bonus of £2 per cent., both free of income tax and payable on July 26, making, with previous payments on account, a total distribution of 7 per cent. on the ordinary stock for the year ended March 31.

NATIONAL TELEPHONE.

The report for the half-year ended June 30, to be presented at the meeting on July 20, states that the income accrued in respect of the business of the half-year amounts to £1,086,507, an increase of £101,232. Working expenses for the half-year amount to £630,250, an increase of £67 190. The net result for the half-year (after deducting the Post Office royalties, amounting to £100,637) is a profit balance of £355,618, an increase of £24,146. The rentals carried forward for unexpired terms of running contracts amount to £1 018,882, an increase of £81,585. Out of the available balance of £268,616 shown by the net revenue account the Board recommend the payment for the half-year of a dividend at the rate of 6 per cent. per annum on the first and second preference shares, 5 per cent. per annum on the third preference shares, 6 per cent. per annum on the preferred stock, and 5 per cent. per annum on the deferred stock. It is also proposed to transfer £110,000 to the reserve fund and to carry forward the balance of £9,699. The sum of £477,166 has been expended on capital account during the half-year in the erection of 22,405 additional exchange and private stations and in the construction of underground works.

NEW COMPANIES REGISTERED.

Johnson Secret Wireless Telegraph and Telephone Testing Syndicate, Limited.—Capital, £15,000. Objects: to acquire the interests and patents of the vendors in the Johnson system of secret wireless telegraphy and telephony, together with all subsequent improvements thereon by the inventor; to test and develop the said system; to promote an exploitation company, to be called the Johnson Secret Wireless Telegraph and Telephone Co., Limited, the nominal capital of which is intended to be £250,000. Registered office: 40, King-street, Cheapside, E.C.

Dewsbury Electric Manufacturing Co., Limited.—Capital, £5,000. Objects: to acquire the business of friction, derrick, and locomotive crane overhead traveller makers, machinery merchants, and general engineers, carried on at 22, Listerhills-road, Bradford, and elsewhere as Roberts and Kaye; to adopt an agreement with C. H. Kaye, W. G. Thomson, and J. Bentley, and to carry on the said business and that of electrical engineers, manufacturers of and dealers in electric, magnetic telegraphic telephonic, and other appliances and apparatus, etc. Registered office: Engineering Works, Kilpin-hill, Heckmondwike.

Musselburgh and District Electric Light and Traction Co, Limited.—Capital, £120,000. Objects: to carry on the business of railway and tramway proprietors, suppliers of electric light and power, electrical engineers, and the like; to adopt an agreement with the National Electric Construction Co., etc. Registered office: Queen Anne's-chambers, Westminster, S.W.

X Electric Accumulator Co., Limited.—Capital, £60,000. Objects: to acquire from E. L. Oppermann, of 21, Ashworth-mansions, Elgin-avenue, W., the benefit of certain existing inventions in relation to the manufacture of plates for secondary batteries or accumulators, etc. Registered office: Leadenhall-street, E.C.

Lien Registered.

Chiswick Electricity Supply Corporation, Limited.—Issue on June 21 of a debenture for £100, part of a series created by resolutions of Nov. 2, 1900, and March 8, 1901, to secure £50,000, charged on the Company's undertaking and property, present and future, including uncalled capital. Holder, Miss H. Heybourne, Clive Cottage, The Warren, Manor Park, E. No trustees. Total amount previously issued of same series, £33,700.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Leicester.—Tenders are required for telephone cables, etc., for the Water Committee. Tenders by July 17.

Bath.—The Corporation invite tenders for a storage battery. Tenders by July 17. See advertisement.

Turnu-Severin (Roumania).—The Mayor invites tenders for the electric lighting of the town. Tenders by Sept. 10.

West Ham.—The Council invite tenders for the erection of tramway offices and car depot, Greengate-street, Plaistow. Tenders by July 25.

Olympia 1905 Exhibition.—The Executive Committee invite tenders for the loan or hire of 300-kw. direct-coupled steam set. See advertisement.

South Shields.—The Town Council invite tenders for the laying of the permanent way for the service line to the car-shed in Dean-road. Tenders by 22nd inst.

Leeds.—Tenders are invited for the supply of lamp-pillars, irons, carriages and furniture, and glass for lamps for one year, for the Street-Lighting Committee. Tenders by July 18.

Brussels.—The Government Telegraph Department require tenders for 14,700 pine telegraph poles. Specification 76 may be obtained from their office at Brussels. Tenders by Aug. 9.

Alicante (Spain).—The Harbour Board (Junta des Obras del Puerto) require tenders for two electric cranes, capable of lifting 10 000 ko. and 1,500 ko. respectively. Tenders by Sept. 15. Estimate, 107,010·10 pesetas.

Loughborough.—Tenders are invited for the supply of materials and stores for the year ending July 31, 1906, for the electricity works. Tenders to the Borough Electrical Engineer by July 18. See advertisement in last issue.

Calanas (Spain).—The Municipality require tenders for the installation and working for 10 years from Jan. 1, 1906, of the electric lighting of the town. Tenders by July 27 to the Alcalde of Calanas, province of Huelva, Spain.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

Merthyr Tydfil.—Tenders are invited by the Urban District Council for the erection of refuse destructor plant capable of effectually burning 120 tons of refuse per day, together with all buildings and contingent works connected therewith. Tenders by Sept. 1.

Neath.—The Rural District Council invite tenders for the supply, etc., of electric light and power mains, sub-stations, switchboards, feeding pillars, switch pillars, excavations, and other works in connection within their area. Tenders by July 17. See advertisement.

Leeds.—Tenders are invited for the supply of lamp-pillars, irons, carriages and furniture, and glass for lamps for one year. Forms of tender and specification may be obtained, and samples inspected, at the office of the Superintendent of Street-Lighting, Springwell-street, off Whitehall-road, from 9 to 11 a.m. daily. Tenders by 10 a.m. on July 18.

Stourbridge.—Tenders are required for the wiring of the workhouse buildings for electric light, also for the installation of a plant for working the same; also for the installation of gas-pipes and fittings, according to specification which can be seen at the Clerk's Office. Tenders to Mr. George Francis James, clerk to the Guardians, 12, Hagley-road, Stourbridge, by 12 noon on July 18.

Ebbw Vale (Mon.).—Tenders are invited for the following, for the Ebbw Vale Urban District Council: (Section A) cables; (B) overhead lines; (C) street lamps and fittings; (D) meters. Specifications, etc., may be obtained at the offices of the consulting engineer, Mr. Reginald P. Wilson, 66, Victoria-street, Westminster. Tenders to the Clerk of the Ebbw Vale Urban District Council by 12 noon on Aug. 5.

Dublin.—Tenders are invited for the supply of three electric locomotives for haulage of refuse wagons on the city tramways; nearly 1,000 yards run of street tram tracks and electricity mains, overhead trolley wires, with street posts and connections; two electric and one steam capstan, etc. Specification, etc., may be inspected at the office of the city engineer, Mr. Spencer Harty, City Hall, Dublin. Tenders to the Chairman, Cleansing Committee, 3, Cork-hill, Dublin, by 12 noon on July 25.

London, S.W.—The London County Council invite tenders for the roadwork and platelaying required for the reconstruction for electrical traction on the conduit system of the tramways (*a*) from the authorised tramways in Red Lion-street, via York road, Battersea Park-road, Nine Elms-lane, Albert-embankment, and Lambeth Palace-road to Westminster; (*b*) along Lambeth-road; and (*c*) along Falcon-road; and for the execution of certain paving works in connection therewith. Tenders by 18th inst.

Erdington.—Tenders are required for the construction of Section No. 1 of the Erdington tramways, comprising the laying of the permanent way, including copper bonding, wood block paving, and other works incidental to the laying of about 2½ miles of double-track tramway, for the Tramway Committee. Tenders to the joint engineers, Mr. Robert Green (of Messrs. Pritchard, Green, and Co.), of 37, Waterloo-street, Birmingham, and Mr. Herbert H. Humphries, engineer to the Council, Public Hall, Erdington.

Municipal Board of Mussoorie (India).—The Municipal Board invite tenders for the supply, delivery, and erection at sites, in complete working order, of the following plant: (*a*) steel power pipes; (*b*) water-motors; (*c*) alternators with exciters; (*d*) switchboards with instruments and apparatus; (*e*) transformers; (*f*) induction motors; (*g*) pumps; (*h*) workshop machines. Also for the supply and delivery of the following: (*a*) bare copper wire for overhead mains; (*b*) insulators and lightning arresters; (*c*) arc and incandescent lamps; (*d*) telephone equipment; (*e*) workshop tools; (*f*) general stores. Tenders by Oct. 23. See advertisement.

RESULTS OF TENDERS.

Darlington.—The Council have accepted the tender of Cox-Walker, Feethams, Darlington, for switchboard extension and booster.

Gillingham.—The Council have accepted the tender of Babcock and Wilcox, Oriel House, Farringdon-street, London, E.C., at £1,010, for one water-tube boiler and superheater.

Lynmouth.—The following tenders have been accepted for a 100-kw. hydro-alternator: Escher, Wyss, and Co., Zurich, hydraulic portion; British Thomson-Houston Co., Rugby, alternator portion.

Loughborough.—The Council have accepted quotations of the Union Electric Co. for four electric arc lamps at £25; and Hardy and Padmore, Worcester, for four lamp columns, at £11. 1s. each.

Bradford.—The Council have accepted the tender of the Webster Electrical Engineering Co., Thornton-road, Bradford, for the lighting of block A of the Grange-road new Council schools by electricity.

Mitcham (Surrey).—The Guardians of Holborn Union have accepted the tender of Ruston, Proctor and Co., Lincoln, at £725, for supplying and fixing at their workhouse, Western-road, Mitcham, Surrey, a new Galloway steam boiler.

Darlington.—The following tenders have been received for supplying and delivering at the electricity works seven tons of 12in. by 6in., and 12in. by 5in. steel girders, with angle plates, bolts, etc., for the Corporation: Cleveland Bridge and Engineering Co., Darlington (accepted). Also tendered: Teesdale Bros., Darlington; Wheatsoe Foundry Co., Darlington; Hall and Pickles, Newcastle.

London County Council.—The tender of C. J. Webb and Co., London, at £3,367. 9*s.* 8d., for the supply of the uniform clothing required for the year ending June 30, 1905, for tramway drivers, conductors, etc., has been recommended by the Stores Committee for acceptance. The Highways Committee have recommended that the offers of G. Skey and Co. to supply an additional 250,000 stoneware cable ducts for the sum of £3,193. 15s., and of Stanley Bros. to supply an additional 500,000 ducts for the sum of £6,800, be accepted.

Aston Manor.—The following tenders have been received for the overhead electrical equipment of the tramways, for the Corporation:—

Brush Electrical Engineering Co.*	£4,338 5 4
R. W. Blackwell and Co.*	4,436 5 3
Johnson and Phillips*	4,567 11 1
Brush Electrical Engineering Co. (accepted)†	4,505 15 7
British Insulated and Helsby Cables*	4,627 2 6
British Electric Equipment Co., 11, Queen Victoria-street, London, E.C.	4,651 17 5
R. W. Blackwell and Co.†	4,751 4 1
British Insulated and Helsby Cables†	4,902 6 6

*Including paper lead-sheathed cables. †Including vulcanised bitumen cable.

Digitized by Google

Partick.—The Council have accepted the following tenders for the supply of plant at their electricity works: Babcock and Wilcox, boiler and coal conveyor; Cowans Limited, Springfield-lane, Salford, Manchester, switchboard extensions; British Insulated and Helsby Cables, Prescot, Lancs., feeder cables.

Stepney.—The Borough Council have received the following tenders for improving the ventilation of the engine-room at the electricity works: F. W. Potter and Co., Phipps-street, E.C., £74 (accepted); J. Keith and Blackman Co., Farringdon-avenue, E.C., £91. 10s. The tender of Gwynnes, Limited, 81, Cannon-street, E.C., at £73. 15s., for a motor-driven centrifugal pump, has also been accepted.

Burton-upon-Trent.—The following tenders have been received for the construction of permanent way, including paving for a route length of 1¾ miles of tramways, together with works in connection with the road widening and alteration of levels, for the Corporation:

G. F. Tomlinson, Derby (accepted)	£12,655 0 6
G. Holloway, Wolverhampton	13,495 10 4
A. Krauss and Son, Bristol	13,614 10 9
G. Law, Kidderminster	14,152 8 5
T. C. Starkey, Hull	14,231 11 6
G. Wimpey and Co., Hammersmith	14,678 14 6
Meredith Bros., Gloucester	14,679 10 7
A. Graham and Sons, Huddersfield	14,706 18 8
Dick, Kerr, and Co., London	14,765 6 7
Bennie and Thompson, Warrington	14,773 10 1
W. Underwood and Bro., Dukinfield	14,807 10 6
British Electric Equipment Co., London	14,897 6 8
E. Taylor, Blackpool	15,148 1 9
W. Griffith and Co., London	15,538 19 0
G. Freeman and Sons, Hollinwood	16,679 14 5
R. C. Brebner and Co., Edinburgh	16,708 10 10
R. W. Blackwell and Co., London	18,123 11 4

London, S.W.—The following tenders have been received for electric light installation, South Battersea station and Westminster (new) station, for the London County Council:

South Battersea station.

Tamplin and Makovski	£251 0 0
O. Clark and Co.	199 17 6
W. H. Johnson	195 0 0
Durell and Co.	189 15 0
Barlow and Young	185 0 0
F. J. Ooleby and Co.	182 10 0
R. Dawson Limited	182 0 0
A. H. Marshall, 270, High-road, Leytonstone (accepted)	155 10 0

Westminster station.

Tamplin and Makovski	326 0 0
O. Clark and Co.	290 19 0
W. H. Johnson	274 0 0
Durell and Co.	266 11 0
Barlow and Young	260 0 0
R. Dawson Limited	249 0 0
F. J. Ooleby and Co.	235 0 0
A. H. Marshall (accepted)	196 10 0

London, W.—The following tenders have been received for the repair of the electric bells and fire-alarms at the infirmary, for the Paddington Board of Guardians:

Tamplin and Makovski, 27, Charles-street, Haymarket, S.W.	£250 0 0
London and Provincial Telephone and Fittings Co., 78, Queen-street, Cheapside, E.C.	199 5 2
Donnison, Sillem, and Co., 116, Great Portland-street, W.	184 0 0
W. J. Bishop and Co., Faraday Works, Gladstone-road, Croydon	179 14 0
Beam Co., 55, Barbican, E.C.	179 0 0
Walsall Electrical Co., 116, City-road, E.C.	143 19 10
W. Winn, 106, Union-street, Borough, S.E.	120 0 0
F. W. Brock, 287, Shirland-road, Paddington	115 13 0
Comyn, Ching, and Co., 54-58, Castle-street, Long-acre, W.C.	109 0 0
Jackson Bros., The Broadway, Plaistow, E.	102 5 0

W. J. Fryer and Co., Bravington-road Works, Harrow-road, W.	97 0 0
Private Wire and Telephone Installation Co., 5, Palmer-street, Westminster, S.W.	91 15 0
Western Engineering Co., The Vale, Acton, W.	89 15 0
G. and H. Turner, 11, High-street, Harlesden, N.W.	78 6 0
R. H. and J. Pearson, 141, High-street, Notting Hill-gate, W. (accepted)	75 0 0
Telephone and Electrical Installation Co., 11, Queen Victoria-street, E.C.	75 0 0
Holmes and Cooper, 9, Balfern-street, Battersea, S.W.	71 5 0
J. Bryden and Sons, 90, Gloucester-road, S.W.	66 0 0
Electrical Engineering and Maintenance Co., 49, Lime-street, E.C.	49 0 0

The Lighting of Trains.—Although electrical illumination is making progress, it appears that compressed oil gas still holds the field in regard to trains. Over 150,000 carriages and 5,000 locomotives have been fitted with this illuminant as devised according to Pintsch's system, and experiments in the direction of improving it are still being carried on with satisfactory results. It is stated that Pintsch's Patent Lighting Co. have recently introduced incandescent burners which give a more powerful light and, at the same time, reduce the consumption of gas. The increase of illuminating power is about 300 per cent. compared with the old system, and the gas consumption is cut down by about one-half.

BUSINESS NOTES.

TRACTION.

Leeds.—The Corporation have pronounced against ½d. stages.

Bolton.—The Corporation have decided to grant the tramway employés a six-day vacation.

Sunderland.—The Tramways Committee are to consider the question of a tramway over the Wear.

Erith.—The Urban District Council have fixed the 24th inst. as the date for the completion of the tramway system.

North Lindsey.—The Light Railway Commissioners have approved of this scheme, which is expected to cost £80,500.

Wigan.—The line to Standish has now been completed, the construction having been expeditiously carried out by Messrs. J. G. White and Co.

East Barnet.—The Urban District Council and the Herts County Council are at variance over the street widenings in connection with the light railway scheme.

Bournemouth.—Representations are being made to the Corporation by the inhabitants of Branksome in regard to the proposed extension to that place now being carried out.

Brompton and Piccadilly Railway.—The London County Council have approved the company's plans for additional entrances and exits at Cranbourn-street Station.

British Electric Traction Co.—The directors propose to pay a dividend at the rate of 6 per cent. per annum for the half-year to March 31, making 6 per cent. for the year.

Scarborough.—There were 42,106 passengers carried on the trams during last week, compared with 30,740 during the previous week, and 46,798 during the corresponding week last year.

Nottingham.—The Tramway Committee do not recommend the introduction of motor 'buses for Sneinton, but the question of a tramway service is expected to be reconsidered shortly.

Durham.—The Town Council have decided to make strong representations to the Board of Trade as to the delay of the Electrical Power Distribution Co. in providing a tramway service.

Hastings.—A dozen cars have been dispatched from Preston by Messrs. Dick, Kerr, and Co. for the tramway system. Preliminary tests have been carried out in the Cambridge-road rails.

Holmfield and Southowram.—The Light Railway Commissioners have submitted to the Board of Trade for confirmation an order authorising an extension of time for the construction of this line.

Swansea.—At a meeting of the Electricity Committee the engineer reported that the electrical energy for the working of the trams on the Brynhyfryd and Morriston sections would probably be ready by the end of August.

Ettrick Bay (N.B.).—The Ettrick Bay tramways extension has been completed, and was expected to be inspected by the Board of Trade's representative yesterday. A *plébiscite* is to be taken on the question of Sunday cars.

Broughty Ferry.—A staff of workmen last week began operations in connection with the construction of the tramway line between Dundee, Broughty Ferry, and Monifieth, at a point in the Monifieth-road near the Whinny Brae.

Darlington.—The receipts from the Corporation trams are slightly on the up grade. The return for May showed a revenue of 6·35d. per car mile. For the last five weeks the revenue was 6·98d. per car mile. Halfpenny fares are to be retained.

Reading.—The Caversham Urban District Council have passed the following resolution: "That a committee of five be formed from this Council to confer with the Reading Corporation with a view to the extension of the tramways to Caversham at an early date."

Blackpool Electric Tramways (South).—An extraordinary general meeting was held last week for the purposes of passing resolutions for dividing the assets of the company, and for the voluntary liquidation of the company. All the necessary resolutions were passed unanimously.

Middlesex County Council.—A further section of the County Council electric tramways from the High-road, Wood Green, through Hornsey, to the foot of Muswell-hill, and thence to the Alexandra Palace has been completed. It is anticipated that the cars will be running by the end of the month.

Oldham, Saddleworth, etc., Tramways Bill.—In the House of Commons on Monday the Examiners of Standing Orders ordered the Oldham, Saddleworth, and District Tramways Bill to be set down for second reading, the forms of the House having been complied with. The measure has already passed the Lords.

Bury.—At a special meeting of the Town Council a proposal to rescind a former resolution with the object of extending the Bolton-road tramways to the borough boundary so as to couple up *via* Black-lane with Radcliffe was considered, but the matter was eventually postponed in the absence of the chairman of the Tramways Committee.

Llandudno.—The Board of Trade have granted to the Llandudno and Colwyn Bay Electric Traction Co. an extension of time for the construction of the light railway from Llandudno to Colwyn Bay till the end of the present month, on condition that good progress is made in that time and that satisfactory assurances are given that the line will be completed forthwith.

Derwent Valley.—It is stated that the inquiry by the Light Railway Commissioners into the application of the Escrick and Riccall Rural District Councils for an extension of time for the compulsory purchase of lands for the projected light railway from Duffield to

Digitized by Google

Stamford Bridge, which was to have been held at the end of this month, will not now be taken till the autumn.

New Paris Underground Railways.—The French Chamber of Deputies has approved of the establishment of two new lines of underground railways in Paris, connecting the north of the city with the south. The *Paris Bourse* announces that one of these lines will run from the Gare St. Lazare to the Saint Ouen Gate, and the other from the Gare de Montparnasse to the Porte de Versailles.

Stockport.—The new route of electric tramways between Stockport and Hazel Grove was officially inspected on Tuesday of last week on behalf of the Board of Trade by Colonel von Donop, R.E. Colonel Donop remarked that he had never seen a better track in England. Afterwards the Edgeley route was inspected. In the afternoon the route was opened for passenger traffic. The contracting engineers are Messrs. J. and W. S. Briscoe.

Lowestoft.—At the monthly meeting of the Town Council last week the Tramways Committee reported that the traffic receipts for the first three weeks in June amounted to £605. 0s. 2d., compared with £540. 19s. 10d. during the same period last year. The suggestion of running a service of cars along Denmark-road at certain hours of the day had been considered, but the committee were unable to recommend its adoption. The report was adopted.

Sale.—At the meeting of the Urban District Council the chairman announced that an arrangement had been arrived at with the Cheshire County Council whereby in connection with the proposal to lay the tramway along Northenden-road a minimum width of carriageway of 27ft. should be obtained by lessening the footpath width. There was a prospect of the Manchester Corporation proceeding with the tramway along Manchester-road to Altrincham boundary shortly.

Croydon.—The following minute of the Tramways Committee was approved at last week's meeting of the Corporation: "Read letter from the British Electric Traction Co., stating that an application had been made by the secretary of the Croydon General Hospital for consent to alms-boxes being placed in the cars, and submitting a sample box for approval. The committee recommend that the Council raise no objection to the boxes in question being fixed in the cars."

Chili.—The *Diario Oficial* of Chile of April 14 contains a decree authorising Messrs. Manuel and Horacio Valdes Ortúzar to construct and work an electric tramway (1·440m. gauge) for the conveyance of passengers and goods between Santiago and San Bernardo. The *Diario* may be seen at the offices of the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, London, E.C., any day between the hours of 10 a.m. and 5 p.m. (Saturdays 10 a.m. and 1 p.m.)

Wakefield.—The question of utilising tramway poles as sewer ventilators is under the consideration of the Town Council, and the city surveyor has been instructed to submit a plan to the Wakefield and District Light Railways Co. showing how the connections to the poles are to be made. The Wakefield and District Light Railway Co. have published notice of their intention to apply for an extension of time in which to complete the tramways authorised by their order obtained in 1902.

Newport (Mon).—It is found that the expenditure in working the trams is below the average of similar undertakings in the country, but the receipts per car mile are also below the average. For the past year there is a gross profit of £7,381. 1s. 7d., but after payment of interest and sinking fund (£7,976. 7s.), there is a deficit of £595. 5s. 5d. The Corporation, however, gives some very long stages. There has been considerable delay over the Port Tennant section, but it is expected that a trial trip will be run shortly.

Yarmouth.—At last week's meeting of the Corporation the general manager (Mr. Frederick L. Turner) reported that from June 2 to 23 122,283 persons had been carried at 1d. fares, 20,676 at 2d. fares, 2,280 workpeople, and 335 scholars; 955 parcels were also carried. The receipts amounted to £693. 3s. 10d., an increase of £124. 2s. 6d. compared with last year. The Corporation propose to link up the entire tramway system by going across the Haven Bridge, and the surveyor has been instructed to report on the subject.

Heywood.—At the meeting of the Bury Corporation last week, Mr. Spencer objected to a tender for six new cars, and submitted that the Bury Council were no nearer a settlement with Heywood than they were six years ago. They had no agreement with Heywood. Every agreement proposed either by Bury or Heywood had, so far, been wriggled out of in a most inconceivable fashion, and he considered it unnecessary to go forward with the provision of cars at the present time. The minutes were amended so as to read that tenders for the six cars should be obtained from several firms.

Mansfield.—The first trams ran through Mansfield Market-place and thence over the Albert-street and Nottingham-road route last week, the trial runs being very satisfactory, and the Board of Trade inspection was expected to take place on Tuesday. Nothing has yet been decided as to the service when the cars are running, but a half-hour service until 7 a.m. and subsequently one of 15 minutes will probably be tried first as an experiment. There will be no season tickets, but books of tickets can be purchased at a discount on the full charge, and scholars' tickets will be sold in packets.

Chicago.—It is reported that the Mayor of Chicago, discouraged by the opinions of Mr. Dalrymple as to the applicability of municipal ownership to Chicago, has come to the conclusion that the scheme which he has favoured for the management of the city's traction by the municipality must be dropped for the present. The proposal has been made to the mayor to hand the tramways over on a 20 years' franchise to a body of well-known Chicago citizens, and that the money for the company should be raised by public subscriptions. The city has the right to buy the property at any time at a valuation.

Weston-super-Mare.—The Light Railway Commissioners have held an inquiry into the application for powers to construct a light railway at Weston village from the terminus of the present electric trams to the top of Lansdown. Mr. Michell, representing the promoters, stated that the capital was £15,000, and the great object would be to give access from Bath and district to Lansdown, with its splendid views and bracing air. Mr. H. L. Godden, the engineer to the scheme, stated that he believed if the railway were constructed Lansdown would become a suburb to Bath like Clifton is to Bristol. The Commissioners intimated that they were prepared to sanction the line on the condition that the promoters widened Weston High-street.

Leicester.—On Tuesday afternoon, as the driver of a baker's cart was coming out of Gwendolen-road, in the direction of Humberstone-road, he noticed an electric car approaching him from the direction of Humberstone-road, and took a wide sweep to avoid it. He cleared it all right, but in doing so ran in front of a car coming from the direction of the Evington-road. This car, which had gained impetus while coming down the incline, dashed into the rear of the cart with considerable violence and pushed it into the tram coming from the opposite direction. The cart was sandwiched between the two cars and smashed to pieces. The driver and boy of the bread van were thrown violently out on to one of the tramcars. The driver was seriously injured, but the boy escaped with slight wounds.

Folkestone.—At the meeting of the Corporation last week, the town clerk reported that the committee appointed by the Council had attended the conference of representatives of the local authorities of Folkestone, Hythe, Sandgate, and Cheriton, when the following resolutions were passed: "That this meeting is of opinion it is desirable that a system of tramways should be established within the districts of Folkestone, Sandgate, Hythe, and Cheriton." "That in the opinion of this conference, the local authorities of Folkestone, Hythe, Sandgate, and Cheriton should work together in the matter of tramways, but this resolution is not intended to commit any of the local authorities to any particular scheme, and is subject to the approval or otherwise of the several councils here represented." The town clerk suggested that the Corporation should authorise the sub-committee to attend and take part in such further conferences between representatives as might be thought desirable, which was agreed to.

Pontypridd.—An encouraging report was made to the Tramways Committee by the engineer on the working of the undertaking during the first three months. He stated that, after paying working expenses and setting apart a sum for sinking fund, a profit of £35 had been made. In April the profits reach £51, but in May there was an adverse balance of £59. For the three months, however, they were still £30 to the good. At a meeting of the Electricity Committee Mr. W. Jones enquired on what authority the engineer charged the tramways 1½d. per unit, whereas the power cost them at the generating station 2d. per unit. The engineer remarked that he thought the price had been agreed upon. It was stated that no resolution had been passed, and Mr. Hopkin Morgan then proposed that they continue to charge the tramway department 1½d. per unit, and argued that in the near future they would be able to produce energy at even lesser cost. Mr. William Jones moved an amendment that 2d. be charged, maintaining that one department should not benefit at the expense of another. The motion was carried.

Sheffield.—The Corporation authorities had a car specially illuminated with electric light in view of the visit of the King and Queen. The decorative effect was quite brilliant, and aroused much admiration among the inhabitants. The work was carried out under the personal direction of Mr. Yerbury, chief electrical engineer; Mr. Marsh, electrical superintendent; Mr. Barrow, rolling-stock superintendent; and Mr. Nicholson, car erection superintendent. Another record has been established in the Sheffield tramway receipts for the past quarter. The income for the 13 weeks was £63,182. 6s. 7d., and the amount received in any preceding quarter which was anywhere near that sum was £62,182. 19s. 6d. for the third quarter of last year. The only other occasions on which £60,000 has been exceeded were the third quarter of 1903, when the total was £61,214 11s. 5d., and the second quarter of last year, £60,336. 19s. 9½d. For two weeks during the past quarter the takings were over £5,000. In no previous quarter's return has this occurred. For Easter week the takings were £5,141. 6s. 8½d., and for Whit week £5,557. 6s. 3½d.

Bootle.—At the meeting of the Town Council it was reported that the town clerk had had correspondence with the Liverpool Tramways Committee, who were now prepared to work the proposed tramways in Breeze-hill, Balliol-road, and Miller's Bridge, and the short length in Regent-road, upon the Corporation obtaining a provisional order therefor, and to continue the Breeze-hill line to Walton Church, and pay an additional rental in respect of that line, but that they were not prepared to operate the Linacre-lane and Aintree-road route at present, in consequence of the non-construction of Aintree-road, such new tramways to be constructed and worked under the existing agreement of Sept. 1, 1902. The Highways Committee were of opinion that the proposed Breeze-hill line should not be laid unless the Liverpool Council first agree that such line shall be used for passenger traffic only, but that the proposed line *via* Aintree-road, and that alone, may be used for goods traffic, and that the Council's resolution of Feb. 1, 1905, should be amended accordingly. The recommendation of the Highways Committee was substantially approved.

Cleckheaton.—The renewed application of the Yorkshire (Woollen District) Electric Traction Company that their powers, so far as they relate to the construction of the Hartshead Moor branch of their tramways scheme, shall be allowed to lapse, is meeting with determined opposition from Cleckheaton, where the delay in the commencement of this section has already caused some indignation. So far as Cleckheaton is concerned, this particular section is an important link in the traction company's Spen Valley scheme, and its speedy completion was regarded as so much a matter of certainty that the District Council laid a traction cable in Westgate, the main thorough-

Digitized by Google

fare up the Hartshead Moor, at a cost of £500. As the situation stands at present, there is a goodly population between the Cleckheaton Market-place and Hartshead Moor and along Hightown Heights unserved by the cars, and so far as the company's line does run up from Liversedge to Hightown its effect is to tap the district for the benefit of Heckmondwike and Dewsbury. This is a sore point with the Cleckheaton tradesmen, who complain not only of a diversion of trade from this side of the valley, but also from the Gomersal side. The District Council have addressed a strong protest to the Board of Trade against the proposed lapsing of the traction company's powers.

Barcelona Tramways Co.—A meeting has been called for July 21 in order that a resolution may be submitted confirming an agreement, dated June 26, between the company and the Société Financière de Transports et d'Entreprises Industrielles for the sale of the company's undertaking. According to a circular issued to the shareholders, the purchase price is £637,000, of which a deposit of £5,000 has been paid; a further sum of £245,000 is to be paid on completion of the notarial transfers of the concessions, and the balance of £387,000 after the transfer to the purchasers has been completed with all necessary formalities. The company is to retain possession of the tramway until the final payment has been made; but the profits are to belong to the purchasers as from the date of payment of the £245,000, the company receiving 5 per cent. interest on the balance of £387,000 as from that date. The directors estimate that, after redeeming the outstanding debentures and debenture stock, providing for all charges and liabilities, and paying all expenses, the purchase price, plus accrued and accruing profits, will be sufficient to repay the preference capital at par, with accrued interest, and to make a distribution of at least £14 per ordinary share. Since the signing of the contract, a scheme for the unification of the company's concessions has been approved by the municipality of Barcelona. It is proposed that, in consideration of the special services of the directors in negotiating and carrying this contract into effect, a sum of £5,000 should be voted to them.

North-East London Bill.—The scheme for the construction of a railway, partly in tube and partly in the open, to serve the north-eastern districts of London was passed on Tuesday by the Select Committee of the House of Commons. The scheme is practically the same as that which came before Parliament two years ago, and was then rejected on financial grounds. The scheme is for a tube railway from the Monument to Hackney, and from the other side of the Hackney Marshes a continuation of the line as an ordinary electric railway in the open. Passing through Shoreditch, Hackney, Walthamstow, and Chingford, the line will terminate at Waltham Abbey. Its total length will be 14½ miles, of which about four miles only will be in tube. This has, of course, very greatly decreased the cost of construction, which is estimated to average about £275,000 a mile. In giving the committee's decision, the Chairman said that they passed the preamble of the Bill on certain conditions. The promoters must raise one-half of their capital from the date of the passing of the Bill and must have commenced construction within two years of the same date. Further, sufficient room must be left between the top of the tubes and the surface of the ground between the Monument and Hackney to allow of the construction of another set of tubes (presumably those of the Hammersmith and North-East London Co.), and the workmen's fares to Walthamstow from the City must not be higher than those of the Great Eastern Railway Co.

Aberavon.—The Bill confirming the order of the Board of Trade with regard to Aberavon tramways came last week before the Select Committee of the House of Lords. The Glamorgan County Council and the National Telephone Co. had petitioned against the Bill, but the latter withdrew their opposition. Mr. Forbes Lankester, on behalf of the County Council, raised the preliminary objection that the consent of the local authority had not been given to the use of the main road, and that, therefore, the Board of Trade had acted *ultra vires* in making the order. Mr. Ram, for the promoters, suggested that if the Board of Trade was wrong an injunction could be obtained from any judge sitting in chambers. The Chairman said the committee were unanimous in holding that the Board of Trade had acted *ultra vires*, and, therefore, they struck out the tramway upon the main road. Mr. Ram said he would consider with his advisers whether it was worth while going on with the rest of the scheme. After a brief consultation, Mr. Ram said he would prove the preamble of the Bill, and would ask the committee to pass so much of the Bill as was not affected by their decision. He called Mr. J. Morgan Smith, past mayor, and a member of the Corporation of Aberavon for 20 years, who said he believed it highly expedient for the well-being of the neighbourhood that the tramways set out in the Bill should be laid. The necessary meetings of the Corporation and of the ratepayers had been held, and the Bill had been approved by a large majority—practically unanimously. The Bill, as amended, was passed, and ordered to be reported to the House.

Sunderland.—The inquiry respecting the death of the boy Herbert Curry, who was killed in the tramway smash at Silksworth, near Sunderland, on Whit Monday, was resumed on Wednesday of last week. It may be recalled that, owing to the brakes not acting, the car dashed into the wall at the bottom of a hill. Just before the car started down the hill an inspector boarded it, and took charge of the brake handles. When the inquest was opened, one or two witnesses asserted that the inspector jumped off the car before the bottom of the hill was reached, but this he emphatically denied. The motorman, who was injured, now gave evidence, and said he did not see the inspector jump off, neither was he aware, as had been alleged, a passenger was standing on the driver's platform. The general manager of the Sunderland District Electric Tramways Co. explained that there were three brakes on all their cars—the electric brake, the hand brake, and the slipper brake. The two former on the car which ran away were in perfect working order, but some time before the accident one shoe of the slipper brake had been lost. He maintained that for all practical purposes the electric and hand brakes were amply adequate. "If the slipper brake had been efficient," he was asked, "might not the accident have been avoided?" His reply was "Probably." The jury returned a verdict of accidental death, and expressed the opinion that the causes of the accident were a defective brake, overcrowding of the car, and want of sufficient caution on the top of the hill. They informally acknowledged that the company was now taking every possible precaution in working the line.

Wolverhampton.—At the monthly meeting of the Town Council two reports were presented by the Electrical Tramway Committee—one including an abstract of the accounts of the undertaking for the past financial year, and the second containing a recommendation from the committee that the Council should enter into an arrangement with the British Electric Traction Co. for inter-communication between Wolverhampton and some of the townships outside. Alderman Mander opened the debate by moving the reception of the statement of accounts. He stated that they had made a profit of £192 this year, against a loss of £1,090 last year, a difference of £1,282. He thought they set aside too much for renewal of cars, etc., but he considered it was sound finance to do so. It was the way in which they kept their accounts that made them compare unfavourably with some other towns. If they had kept their accounts in the standard way, they would have a gross profit of £15,000 and a net profit of £4,983, instead of only £192. The receipts per car mile were 10·9d. against 10·3d. for Sunderland, which claimed a profit of £6,632. The total operative cost was ¼d. per car mile less than other undertakings, which spoke volumes for the efficiency of Mr. Shawfield and his staff. With the single exception of the number of units per car mile, Wolverhampton showed a better average in general figures than any other town, and the extra cost in units was accounted for by the better lighting utilised on the Wolverhampton cars. In conclusion, he said they wanted to educate the public into using the cars to the extent they did in other towns. He considered the report was very satisfactory, and should be acceptable to the ratepayers. After some discussion the report was unanimously adopted.

Tube Railways.—Three tube railway Bills were considered last week by the Select Committee of the House of Lords presided over by Lord Lauderdale. The object of the Charing Cross, Euston, and Hampstead Railway Bill is to empower the company to carry out certain modifications of the authorised works in connection with the construction of a station and entrance and exit thereto under the forecourt of the South-Eastern Railway Company's station at Charing Cross. Mr. Blennerhassett, K.C., opposed the proposal on behalf of the Westminster City Council, who desired that the entrance to the underground station, which the Charing Cross, Euston, and Hampstead Railway Company proposed to place on the western side of the forecourt adjoining Brewer's-lane, should be made in Villiers street, where it was intended to have the exit. Sir R. Littler, K.C., objected to the demand of the City Council. The committee, having heard evidence and arguments, decided that the Bill might proceed. The various clauses were adjusted, and the Bill was ordered to be reported to the House for third reading. In the Baker-street and Waterloo Railway Bill the promoters sought power to vary the works in connection with the construction of the authorised subway at Trafalgar-square (so as to give an entrance and exit at a point near to where the extension of the Mall opens out into Charing Cross, in accordance with the wishes of the Office of Works) and of the subway at the Elephant and Castle. The committee found the preamble proved, and ordered the Bill to be reported for third reading. The object of the Edgware and Hampstead Railway Bill is to authorise a deviation of the railway at Golder's Green so as to provide a more convenient junction there with the Charing Cross, Euston, and Hampstead Railway. Opposition was offered by the Golder's Green and Finchley-road Estate Co., but in the result the committee passed the preamble of the Bill, and inserted clauses for the protection of the opponents. The Bill was subsequently ordered to be reported to the House.

Newcastle.—At last week's meeting of the Corporation, the Tramways Committee reported as to an interview which they had had with a deputation from the South Shields Gas Co. with respect to the probable effects of laying the tramway lines on the pipes of the South Shields Gas Co. Plans were submitted, from a perusal of which the deputation maintained that it was obvious that frequent interruption of the tramway service would take place, and great expense result, if the permanent way were laid on the top of the gas-pipes, as the concrete bed of the tramways track would require breaking and reinstating. Furthermore, it was pointed out that the close proximity of the electric cables to the gas-pipes might cause considerable damage through the fusion of the latter, and in one part in particular some amount of risk would exist. The directors had come to the conclusion that the real solution of the problem lay in duplicating the gas-mains, so that they might be laid on both sides of the street and underneath the footpath or other approved position clear of the electric lighting cables. The company, however, could not bear the expense of these alterations, as the existing gas distributing system along the tramway routes provided an ample supply for present requirements. The committee recommended that the company be offered the sum of £1,000 if they would duplicate the gas mains throughout the tramway system, this amount to cover all cost to the Corporation in connection with their obligations to the company. Councillor Grant, in moving the adoption of the report, said that the estimated cost of duplicating the mains along the whole of the routes would work out at something like £5,000. The committee considered that they should in all fairness to the company contribute towards the cost of these alterations, having regard to the fact that the roads along which the tramways would be constructed were a network of service pipes. After some discussion, the committee's report was confirmed by 18 votes to 11. The returns for Race week show that all previous records have been outdistanced. The total takings of the week were £5,586, which is no less than £890

Digitized by Google

more than the sum realised last year. The receipts per tram mile rose from 12·75d. to 14·82d.

London County Council.—The agenda for Tuesday's meeting of the London County Council contained a recommendation that a vote of £19,000 be made in respect of trackwork in the Aldwych subway, the standing orders having been complied with. It was also proposed that votes of £23,200 and £10,000 respectively be authorised in respect of the reconstruction of lines along the Woolwich-road on the conduit system, and the supply of stoneware cable ducts for the northern system, the latter to be supplied by Messrs. G. Skey and Co. and Messrs. Stanley Bros. At the meeting of the Bermondsey Borough Council last week it was decided to make representations to the County Council with a view to the early electrification of the lines in the borough, in accordance with the expressed wish of the inhabitants. The Lewisham Borough Council have carried a resolution asking the County Council to pave the space between the two tracks of tramways and the 18in. outside the tracks with wood paving, leaving the space between the rails of each track to be paved with Norwegian granite setts. At a meeting of the Wandsworth Borough Council last week the Highways Committee reported the receipt of a letter from the County Council stating that it was proposed to apply for powers to construct the suggested tramway from the present Streatham terminus along Streatham High-road with a loop line along Gleneldon-road, Bournevale-road, and Stanthorpe-road, to the county boundary at Norbury. The Highways Committee of the County Council had decided not to recommend the County Council to revive at present the suggestion for the construction of a tramway from Clapham Common to East-hill, Wandsworth, but they would give careful consideration to any representations on the subject which the Borough Council might desire to make. It was recommended that the County Council should be informed that the Borough Council regretted the decision not to proceed with the scheme for the construction of a tramway from Clapham Common to East-hill, that it should be pointed out that the part of the thoroughfare in the borough of Battersea had already been widened in anticipation of the proposed tramways, and that it was very desirable that the tramways at Clapham and Wandsworth should be linked up by a direct line at the earliest possible date. Councillor Cresswell moved that the County Council should be asked whether they proposed in the 1906 session of Parliament to apply for powers to construct a tramway from Clapham Common *via* Northside, Wandsworth Common, East-hill, and Wandsworth High-street, to the junction of West-hill with Upper Richmond-road. With this addition, the Borough Council confirmed the minutes. The County Council propose to adopt the conduit system for the following tramways: the existing tramways from North-street, Wandsworth, *via* York-road, Battersea Park-road, etc., to Westminster Bridge-road; the new tramways from York-road, Wandsworth, at its junction with North-street, *via* York-road, Red Lion-street, South-street, Garratt-lane, and Defoe-road to join the newly-constructed lines at Tooting; the new tramways from Queen-street, Hammersmith, to a point in Lower Richmond-road near the junction of that road with the approach to Putney Bridge. The road between the tramway rails will be paved with granite setts, as difficulties might arise if wood were used between the rails, owing to the closing of the slot by the expansion of the wood. Outside public buildings, churches, etc., some form of silent paving would be employed if the road authority desired. The Council only propose to pave the margins of the tramways for a width of 18in. with wood or granite, to correspond with the remainder of the surface of the roadway. A large part of the thoroughfares is at present macadamised, and the Highways Committee of the Borough Council are of opinion that the whole of the carriageways outside the rails should be paved with wood and the footpaths with artificial stone. The Borough Council's contribution of one-third (not exceeding £91,316) of the net cost of widening Red Lion-street, South-street, Garratt-lane, and Defoe-road was promised on the understanding that the paving works there would be carried out in this manner. The new tramways between Wandsworth and Tooting and Hammersmith and Putney are to be constructed as double lines throughout, and the County Council propose to reconstruct the existing tramways in York-road as double lines, except between Morie-street and Edgel-street and between Ferrier street and Alma road, where it is intended to arrange the existing single line portions as interlaced lines. The Hammersmith Borough Council decided on Wednesday to make representations to the Board of Trade in favour of the overhead trolley system being adopted on the portion of the County Council's Queen-street to Putney electric tramway to be constructed in the borough. In the House of Commons on Wednesday the County Council's Over-Bridge Tramway Bill was read a third time.

LIGHTING AND GENERAL.

Stafford.—The output of current during the last month shows an increase of 6 per cent.

Dudley.—An exhibition of electrical fittings and appliances will be held in November next.

Hayes.—The Hayes Electric Supply Co. intend to apply for a provisional order for the district.

Fochabers.—The Bellie Parish Council have resolved to light the town of Fochabers with the electric light.

Bray.—The question of appointing an assistant electrical engineer has been referred to a special Finance Committee.

Sale of Business.—Particulars of the sale of an electrical manufacturing business will be found in another column.

Removal.—The offices of Siemens Electric Appliances, Limited, have been removed to 12, Queen Anne's-gate, Westminster, S.W.

Woodbridge.—Messrs. Foote and Milne intend to apply to the Board of Trade for a provisional order to supply electricity within the area.

North Metropolitan Electric Supply Bill.—This Bill has passed both the House of Lords and the Select Committee of the House of Commons.

Halesowen.—The Empire Electric Lighting Co. propose to apply to the Board of Trade for a provisional order to enable them to supply the district.

New Title.—The name of the Electric Railway and Tramway Works, Preston, Lancs, has been changed into the United Electric Car Co., Limited.

Electricity Shares.—Shares of the London electric lighting companies fell after the second reading of the London Power Bill in the Commons.

Burgess Hill.—An application of the National Telephone Co. to lay underground pipes along certain streets has been acceded to on certain conditions.

Burnham.—The Slough and Datchet Electric Supply Co. intend applying for a provisional order to include this parish, and have asked the Council to support it.

Durham Electricity Bill.—The Bill introduced for the purpose of confirming the Durham district electric lighting provisional order has been reported for third reading.

Clacton.—The Urban District Council have received four notices from different companies of their intention to apply for orders to supply electricity in the district.

Obituary.—We regret to announce the death of Mr. John Thomas Connolly, one of the directors and one of the founders of the firm of Messrs. Connolly Bros., of Manchester.

Uckfield.—The Urban District Council have deputed the Highways Committee to consider the whole question of public lighting, and the possibility of effecting some improvement.

Newport (Mon.).—The Electricity and Tramways Committee have decided to recommend that on the motor installation account a sum equal to 7½ per cent. be set aside for deterioration of motors.

Seaton.—Messrs. J. and W. Purvis, electrical engineers, Exeter, intend to apply for an electric light provisional order for the area of supply of the urban district. The Council will oppose the application

Lowestoft.—During last month eight new consumers were connected to the mains, representing 279 8-c.p. lamps. There are now 627 consumers connected to the mains, representing 31,852 8-c.p. lamps.

Short Heath.—The Council have asked the Midland Electric Supply Co. if it was their intention to extend their mains into Short Heath district, and what would be the cost per lamp for public lighting.

Aspull.—The District Council are asking the Board of Trade to further extend their electric lighting order. It is stated that a satisfactory arrangement has been arrived at with the Wigan Corporation.

Iceland.—It is reported that the King of Denmark has granted to the Great Northern Telegraph Co. a concession for the laying and working of a telegraph cable between the Shetland and Faröe Islands and Iceland.

Weybridge.—The Urban Electric Supply Co. intend to lay cables from their works to the Weybridge boundary in Oatlands Drive. The surveyor has been asked to arrange with the company to commence the work at once.

Wisbech.—The Local Government Board have, we understand, refused to grant the application of the Corporation for powers to raise a loan of £25,000 for the purpose of establishing a municipal electric lighting department.

Cardiff.—The Electrical and Lighting Committee propose to erect, at a cost of £2,200, a sub-station in Cathays Park, near Park-street, to be exclusively used for the distribution of electric lighting and power within the park.

Alnmouth.—Mr. Percy Harvey, Collingwood-street, Newcastle, electrical engineer, has applied to the Board of Trade for a provisional order to enable him to supply electricity for all public and private purposes within the town.

Newton Abbot.—The Urban Electric Supply Co.'s estimate for wiring the Guardians' building and providing 42 lights is £26. 10s., and the cost of the current 4d. per unit. The estimates are now referred to the Building Committee.

St. Annes.—During May 35,271 units of electricity were sold, as compared with 42,694 in the corresponding period of last year. Up to May 31 there were 75,996 units sold, as against 87,477. The number of consumers is 339, an increase of 75.

Wallsend.—According to the local Press, the supporters of electric light are going to have another try to get part of the town lighted by electricity. The electric company are to be asked to give a price for the efficient lighting of certain new streets.

Wantage.—The Wantage Engineering Co. intend to supply the town with electric light. The Urban District Council do not object to the introduction of electric light into the town upon condition that the introducer apply for a provisional order.

New Issue.—The Northern Counties Electric Supply Co. are issuing at par £100,000 4½ per cent. first mortgage debenture stock, payable as follows: on application, £10 per cent.; on allotment, £40 per cent.; on Oct. 1, 1905, £50 per cent.

Houghton-le-Spring.—The Electric Lighting Provisional Order (No. 7) Bill, which will confirm an order granted to Houghton-le-Spring, has passed the House of Commons, and has been ordered to be reported for second reading in the Upper House.

Wakefield.—A sub-committee has been appointed to confer with the appointed representatives of the Sanitary and Electric Lighting

Digitized by Google

Committees as to the cost of working the destructor and the allocation of such cost upon the several committees concerned.

Wakefield.—The Electric Lighting Committee have made a net profit on the past year's working of £1,283, of which £895 has been repaid to the general district fund in order to write off a loan, leaving a net amount of £392 to be transferred to the reserve fund.

Edinburgh.—Out of the ascertained balance of £21,139 on the electric light account £17,095 is to be credited to the reserve fund and £4,044 to streets account, towards the replacement and depreciation in the streets caused by the electric light department.

Loughborough. — The Gas and Electricity Committee have appointed a sub-committee to consider and report upon the question of a revision of the prices for current for power and lighting, and also on the question of the advisability of revising the existing regulations.

Dover.—The audited accounts of the electricity department for the working of the undertaking since the beginning of last year until March 31 this year show that, after paying all that has to be paid, the sum of £1,475 has been carried forward, leaving a balance of £1,231 in hand

Worksop.—The electrical engineer's plans and particulars of proposed additional plant at the electricity works, at an estimated cost of £800, have been approved. Application is to be made for sanction to acquire an additional loan of £3,000 for electric lighting purposes.

Wandsworth —The Council have decided to withdraw their opposition upon the promoters of the Administrative County of London and District Electric Power Co.'s Bill undertaking to amend the Bill so as to include the borough of Wandsworth in the industrial portion of the area of supply.

Direct United States Cable Co.—The directors recommend a final dividend of 3s. per share, with a bonus of 1s. per share, making a total distribution of 3½ per cent. for the year ended June 30. The sum of £6,000 has been placed to reserve, leaving a balance of about £2,525 to be carried forward.

Redcar.—The Urban District Council have declined to treat with the United Electric Construction Syndicate with respect to their taking over the order obtained by the Council four years ago, and the Council are now negotiating with the Cleveland and South Durham Electric Power Co. for the supply of electricity in bulk.

Bradford.—The Electricity Committee will again recommend the City Council to provide a motorcar for the electricity department. The committee consider that a car is required to enable the necessary constant supervision to be given to the work of mains extensions and also for the overlooking of the general work of the department.

Outing.—The employés of Messrs. Stegmann and Co., electrical engineers, St. John's-hill, Clapham Junction, had a most successful outing to Brighton. Through the unavoidable absence of Mr. Stegmann, the respected chief, the chair was taken by Mr. Stenford, the firm's manager, at the annual dinner, which was partaken of at the Queen's.

National Telephone Co.—The directors recommend the following dividends for the half-year ended June 30 last, after payment of the dividends on the preference shares: at the rate of 6 per cent. per annum on the preferred stock; at the rate of 5 per cent. per annum on the deferred stock, carrying £110,000 to reserve and about £9,500 forward.

Frome.—The Urban District Council have decided to borrow another £11,000 for the purposes of the electrical works. Mr. Medhurst, the Council's consulting engineer, in his last report states that the demand for electricity had been unprecedented for a town of the size of Frome. He hoped this additional £11,000 would carry the works to 1908.

Paisley.—The Gas Committee propose to instal electric plant for supplying power for coke conveyors. On Monday last the staff and employés of the Corporation electricity department, accompanied by the convener (Bailie Fisher) and the chief engineer (Mr. Parkinson), held a successful annual outing. This year the route chosen was the Loch Eck tour.

Ayr.—The burgh electrical engineer, Mr. Roland Marshall, in his last report gives the following figures: number of consumers as per last report 917, connected during month 6—total, 923; number of lamps connected as per last report 38,612, connected during month 158—total, 38,770; units generated as per last report 53,309, units generated during month 55,652—total, 108,961.

Change of Title.—The partnership hitherto existing between Mr. R. G. Tyler and Mr. W. E. Duncan has been dissolved owing to the latter having accepted an appointment in Canada. Mr. Tyler has taken into partnership Mr. E. H. Freeman, A.I.E.E., late of Johannesburg, and they will continue to carry on the business at 20, New Bridge-street, E.C., under the title of Tyler and Freeman.

Easthampstead.—The Mutual Electricity Supply Co. intend to apply to the Board of Trade for an electric lighting provisional order for the Sandhurst parish, and the Camberley Electric Supply Co., of Moorgate-court, Moorgate-place, London, also intend to apply for a provisional order to supply electrical energy for public or private purposes within the area of the jurisdiction of the Easthampstead Rural District Council.

Swansea.—Mr. Prusmann in his last report stated that there were 667 consumers on the books, that the engine, etc., had been removed to the destructor works, and that electrical energy for the working of the trams on the Brynbyfryd and Morriston sections would probably be ready by the end of August. Owing to the heavy cost of extending the mains, etc., he could not recommend the committee to electrically light Libanus Chapel, Cwmbwrla.

Louth.—An inquiry has been held into the application of the Town Council to borrow £17,000 for the purpose of installing electricity within the borough. Mr. Dykes, consulting engineer to the Corporation, said he estimated that the plant would be capable of producing electricity at 6d. per unit, to bring in a total revenue of £3,200 per annum. He estimated expenses at £1,075, leaving a balance of £2,125 to meet interest and sinking fund and depreciation.

Ledbury.—Messrs. Foote and Milne intend to apply for a provisional order to supply electricity within the Ledbury urban district. Two or three months ago a sub-committee was appointed to take into consideration the lighting of the town, and to canvass the townspeople to ascertain the probable number who would adopt electric lighting if established, the probable cost as compared with gas, and all other necessary information. We understand nothing has been done yet.

Croydon.—The borough electrical engineer's last report states that 36 applications have been received for private lighting, being equivalent to 1,444 8-c.p. lamps. Twenty-nine consumers have been connected, being equivalent to 958 8-c.p., and 945 yards of extensions of mains have been carried out. He adds the following figures: Current sold this year—public lighting, 27,357 units (corresponding period last year, 25,675 units); private lighting, 71,807 (68,217); traction, 133,521 (118,210).

Mitchelstown.—All the preliminaries in connection with the electric light scheme have been completed, and it now only remains for the No. 1 Council to invite tenders for the work. The ratepayers are very much in favour of the project, and at a recent meeting in the town hall a resolution to go on with the scheme was passed without a dissentient voice. A memorial in favour of the scheme, and promising to avail of it for domestic purposes, was signed by a large number of ratepayers recently.

Margam.—The District Council have agreed to an application of the South Wales Electrical Power Distribution Co. to run power mains through the district for 30 years, the Council to have the option of terminating the agreement at the end of five years, giving six months' notice to the company; the latter to pay 2½ per cent. on total energy supplied by them to users, minimum £50 yearly. The company is to lay down cables to suit future requirements of the district, and power not to be supplied for lighting.

Maidenhead.—From Sept. 30 next the Town Council will offer, as an alternative to the present flat rate of 5d. per unit for electricity, a sliding-scale rate on the basis of 7d. per unit for a consumption equivalent to one hour per day of maximum demand and 2d. per unit for all additional consumption. The present maximum rate for electricity for power purposes is 2d. per unit, and the Council are prepared to supply for these purposes to large users at lower rates according to the duration of the demand per day.

Felixstowe.—The number of electric light consumers have increased from 225 last November to 250 on June 24. Regarding an account of £120. 0s. 2d. for various works, as approved by the committee and certified by the engineer to the Suffolk Electricity Supply Co., Mr. Woodmancy suggested at the last Council meeting that it would be advisable to appoint the surveyor as deputy engineer to overlook any similar work in the future. Mr. Cowles, the chairman of the committee, said the committee would consider the suggestion.

Perth.—The Town Council have passed a report containing recommendations that on the Perth Bridge 19 incandescent lamps are to be replaced by four arcs fixed to the tramway poles at an initial cost of £10 each, and an annual cost of £11 each for lighting—a total of £44, and a saving of £22. 10s. per annum; and that in King-street 12 incandescent lamps are to be replaced by five arcs fixed on the tramway poles at an initial cost of £10 each, and an annual cost of £11, which would involve an annual increase of £13 on the present system.

Islington.—On the North Metropolitan Electric Power Supply Co.'s Bill coming before the Select Committee of the House of Commons, Sir Ralph Littler, K.C., for the promoters, asked for costs against the Islington Borough Council, who had not given notice of their withdrawal of opposition. The Chairman of the Committee said that the committee had no jurisdiction in the matter of costs. The Bill was now unopposed, and would, consequently, have to come before the Unopposed Bills Committee of the House, when the question of costs could be raised.

Stock Exchange.—The Stock Exchange Committee have been asked to appoint a special settling day in Electro-Pest-Ocal Co.'s 40,795 shares of £1 each, fully paid, Nos. 1 to 7 and 43,508 to 84,295; and to allow the following securities to be quoted in the official list: Cordoba Light and Power Co.'s £100,000 first mortgage sterling 5 per cent. bonds of £100 each; River Plate Electricity Co.'s 119,694 ordinary shares of £1 each, fully paid; 100,000 6 per cent. non-cumulative preference shares of £1 each, fully paid; and £194,684 5 per cent. debenture stock.

London County Council.—On Tuesday it was decided to lend the Battersea Borough Council £8,820 for electric light installation, and the Bermondsey Borough Council £6,796 for electric light installation. Tenders were received for supply, delivery, and erection of four sets of high and low tension switchgear for tramways sub-stations at Battersea, Clapham, Streatham, and Wandsworth; for supply, delivery, and erection at Battersea and Wandsworth tramway sub stations of low-tension feeder switchboards; and for roadwork and platelaying required for construction for electric traction of tramways from Wandsworth to Tooting.

Gillingham.—The resident engineer's last report shows that the equivalent of 7,846 8-c.p. lamps had been connected with the mains since the last meeting of the committee, including 7,745 at the Naval Hospital; that the equivalent of 24,000 8-c.p. lamps had been temporarily connected for the Kent Electric Power Co.; and that there are now, inclusive of the Kent Electric Power Co., 240 consumers, with 46,223 8-c.p. lamps connected. At the last Town Council meet-

Digitized by Google

ing a letter was read from the Kent Electric Power Co. conveying to the Corporation the expression of the company's appreciation of the kindly manner in which the Corporation had rendered assistance to the company.

London Gazette.—Proofs and claims re the Yorkshire Electric Tramways Construction Syndicate are to be sent in by Aug. 19 to Mr. W. A. Andrews, 14, Victoria-street, S.W. A general meeting will be held at 1, Cheapside to receive liquidator's accounts of the Edmondson Electricity Meter Syndicate on Aug. 14. The last day for receiving proofs in the estate of Charles Aubrey Smith, trading as C. J. Smith, electrician, 23, King-street, Regent-street, and residing at 6, Granard-road, Wandsworth Common, is July 26. The last day for receiving proofs in the estate of Edward Lacy, engineering manager, 101, Oakley-street, Lambeth, is July 22. Mr. G. W. Chapman, Bankruptcy-buildings, Carey-street, W.C., is the official receiver.

Pamphlets.—We have received an interesting illustrated pamphlet from the Sunderland Forge and Engineering Co., Pallion, Sunderland, dealing with the induction motors manufactured by that firm. Curves are given showing braking tests of the 15-h.p. induction motor for 220 volts, eight poles, 50 cycles, 725 revolutions. Messrs. Mountain and Gibson (successors to the McGuire Manufacturing Co.), engineers, Eton Fold Works, Bury, Lancashire, have published an illustrated pamphlet descriptive of their works and of their specialities shown at the current Electric Tramway and Railway Exhibition, which include various types of tramway cars, electric motorcars, sweeping, watering, and sprinkling cars, motor trucks for tramways and railways, trolley poles, lifeguards, etc.

Finchley.—An inquiry has been held into the Urban District Council's application for sanction to borrow £23,500 for electric lighting purposes. Mr. Calvert, the electrical engineer, said there were now 496 consumers, averaging 47 8-c.p. lamps each. The Council supplied power to the tramways under a 12 months' agreement. They were under no obligation to supply the company, who had laid their own mains into the Council's works; the company had power of their own. Mr. Calvert then submitted details as follows: machinery, £5,450; water supply, £2 180; buildings, £350; coal, £1,200; sub-station, £5 200; mains, £1,320; distributors, £2,280; streets not specified, £1,770; service connections, £2,200; contingencies, office expenses, inspection expenses, and loan charges, £1,550 — total, £23,500.

Dublin.—The Lighting Committee required a loan of £60,000, £13,000 of which was needed to extinguish the balance of the original extension, and £47,000 to carry them over the work which was immediately pressing. The Local Government Board, however, suggested that instead of going in for successive loans and inquiries they should apply for a comprehensive loan at once. The Lighting Committee, therefore, recommend an application for a loan of £100 000, and that the work should be carried out by their own staff under the superintendence of the city engineer, with power to call in Mr. Hammond for consultation at certain specified fees, not, of course, 5 per cent. on the works as before. A motion to that effect is under consideration. The output of electrical power during the last 12 months has exceeded that of the corresponding period by about 1 000,000 units, and the increase is steadily continuing.

Longton.—The following is the report of the Electricity Committee for the year ending March 31, 1905: "In connection with the electric lighting station there have been added during the year, in incandescent and arc lamps, motors etc., an equivalent of 1,284 8-c.p. lamps, making a total of 6,462 8 c.p. lamps fixed to March 31, 1905. The working profit for the year amounts to £692. 15s. 11d. The balance brought forward from last year (£1,582. 17s. 4d.), together with interest and sinking fund charges £1,218. 7s. 6d.), and the amount of capital written off (£373 4s. 6d.), makes a total of £3 174. 9s. 4d. From this must be deducted £692. 15s. 11d., being surplus of revenue account, and £1,719. 12s. 5d., amount received from gas department, leaving a balance of £762 1s. Your committee also recommend that £300 be set aside as depreciation of plant, thus making a debit balance of £1,062. 1s. to carry forward."

Radiators.—The Sheffield Corporation electric supply department, in advocating the installation of radiators as a means of absolute prevention of down draughts, prints a letter from the Burngreave Congregational Church, in which the minister, the Rev. T. T. Broad, says that, after trying other means, the experiment was made of heating the upper air with 20 electric heater lamps hanging about 7ft. from the ceiling. He says: "The relief was immediate. After a trial lasting since the end of November, 1904, and during the severest months of the year, the testimony is uniform in all parts of the church that this new method of dealing with a great difficulty has been most successful. Before having the heater lamps fixed permanently, public invitations were given to the people to state if they still felt any down draughts. I am glad to be able to say that no complaints have been received, but that all join in declaring that the draughts have been stopped. It is a matter of thankfulness to us all that we have attained this efficient and satisfactory result. Perhaps you would like to know that the heater lamps are usually turned on half an hour before the commencement of the service."

Ipswich.—An inquiry has been held into an application of the Town Council for sanction to borrow £2,438 and £12,851 for purposes of their electric lighting undertaking. Mr. Will Bantoft, town clerk, explained that £2,438 was required for a 350-i.h.p. engine set, and equalising switch, two additional panels on switchboard, and additional pipework for the two new engines. The amount of £7,486 was for balances of retention money and outstanding liabilities on contracts, amounting to £978. 13s. 5d., and liabilities incurred for the additional boiler, engines, and dynamos, pipework and switchboard panels, and the feed-water well. The sum of £5,365 was required for mains extensions, etc. Mr. Ayton, the manager of the undertaking, gave some particulars regarding the enterprise. At the end of their broken financial year ending March 31, 1904, they had 98 consumers, representing 7,580 8-c.p. lamps. At the end of the following year the number of consumers had increased to 209, and the number of 8-c.p. lamps wired and connected to the Corporation mains was 27,557. At the end of June they had 29,927 lamps, and if they added the lamps applied for, the total would now be 30,081.

National Telephone Co.—At the annual staff dinner of the National Telephone Co. last week, Mr. W. E. L. Gaine, general manager, stated that there were 1,155 exchanges working in Great Britain and Ireland, an increase of 60 during the year, and 336,000 stations, an increase of 40,000. The messages numbered 1,000 millions per annum. Whilst their telephone messages had increased by 70 or 80 millions in the year, the total number of telegrams had gone down from 84½ millions to 82 millions. They had 725,000 miles of wire in Great Britain, two-thirds of which were underground. With regard to the negotiations with the Government for the acquisition of the company's undertaking, they had resulted in an agreement which, if it met with the approval of Parliament, would take effect in January of 1912. He regretted the omission from the agreement of adequate and fair provision for ultimately dealing with the company's staff. He added that the agreement as it stood did not represent the views of the directors. However, the last word on this matter had not yet been said, and the staff would have the opportunity of putting its own case before the Select Committee.

Fishing Vessels.—The steam line-fishing vessel "Vigilant," owned by Captain Forbes, Torry, has been fitted with an installation of electric light, and it is thought that the satisfactory results obtained after a thorough test are likely to lead to a general introduction of this system of lighting on small steam vessels. The "Vigilant" has been fitted with a high-speed single-acting steam-engine, coupled direct to the dynamo, on the same bed-plate, suitable for 30 to 35 16 c.p. lamps at 100 volts. This set has been specially designed for the lighting of small steam vessels. The space occupied is only 4ft. by 2ft., an important factor on small boats owing to the limited space available in the engine-room. The main switchboard is fitted close beside the dynamo, with switches to control all the signal lights, etc. The three signal lights are of 32 c.p. each. A portable cluster of three 32-c.p. lamps is fitted where the fishermen haul in their lines, and a similar cluster where they shoot their lines. There are five bulkhead lights in the engine-room casing and wheel-house for deck lighting, cabin, galley, fishroom, engine-room, etc. The wiring throughout the vessel is carried in galvanised iron tubing, and made thoroughly watertight. The installation was carried out within a week under the supervision of Mr. W. Walker, consulting engineer. After three weeks' trial the engineer of the "Vigilant" reports that there has been no increase in the coal consumption, and thus the lighting of the vessel will cost very little more that the initial cost of the installation. The engine, dynamo, and complete installation were supplied by Claud Hamilton Limited, Aberdeen.

Southwark.—The General Purposes Committee are considering a letter from the secretary of the County of London Electric Supply Company stating that they are prepared to submit proposals for dealing with the electric lighting undertaking of the Council on either of the following alternative bases: (*a*) to supply current in bulk for distribution by Council at a price cheaper than it can be generated by the Council; and (*b*) to take over the undertaking on lease and work it for a period of years, and guarantee a sum sufficient to provide sinking fund and depreciation on the capital expended. At the last Borough Council meeting the same committee reported upon a letter from the City of London Electric Lighting Company, in which it was stated that it having been publicly reported that the Council might be disposed to consider an offer to supply electrical energy in bulk upon terms which would enable the Council to produce a considerable annual profit, they would, if the Council supplied information as to their probable requirements, be pleased to state the terms on which they would be able to supply such bulk. Further, that the company being located in Southwark was evidently the best adopted for connecting up with the Council's area of supply, the only requirement being the laying of a feeder main or mains across the parish of St. Olave's. Subject to the work being carried out, the company would begin the supply at once. The committee were informed that the area of supply of the company does not touch the area of supply of the Council, therefore they recommended the Council not to take any action in the matter. This was agreed to.

South Wales Electrical Power Distribution Co.—"Electrics," the official publication of the company, gives the following particulars under the heading of "What the Generating Stations are doing": "In our first issue, under 'Bridgend,' we referred to the erection of a 70-kw. two-phase alternator. This work has now been completed, and is running on load. At Cwmbran the work on the extension is being actively pushed forward. The extension of feeders to Risca to supply the United National Colliery and other customers has been commenced. At Neath the agreements for the supply of electricity in bulk to the Urban District Council of Briton Ferry and the Rural District Council of Neath have been completed, as has also an agreement with the Urban District Council of Llanelly. The extension of the mains to Aberavon is now in hand. The Carmarthenshire Power Co.'s Bill has received the Royal assent, and work on the mains to supply this additional area will shortly be begun. At Pontypridd the third 3,000-h.p. steam alternator has been tested, and will shortly be running on load. The extension of mains to Ferndale is completed. In an article which appeared in our first issue on 'Haulage Gear at the Albion Colliery,' reference was made to the extensions of the system, part of this has now been done, a second 200-h.p. haulage gear being connected to the supply received from this station. The Locketts Merthyr Colliery Company have placed an order with the Westinghouse Company for electrical machinery for various purposes, amounting to about 500 h.p. Surveying is being proceeded with of the high-tension overhead lines from the Cambrian Colliery to the Ogmore Valley."

Glasgow.—The Electricity Committee's accounts for the year ended May 31 show a gross revenue of £186,371. 13s. 11d. and a working expenditure of £71,721. 6s. 2d., which, with the deduction of interest on loans amounting to £38,182. 7s. 11d. and £15,475 to the sinking fund, leaves a balance on the year's working of £60,992. 19s. 10d. From this total there has been deducted £2 875. 10s. 11d., being the proportion of the cost of lamps and fittings supplied to consumers consequent on change of voltage, and the net balance over expenditure is thus £58,117. 8s. 11d. A sum of £41,840. 17s. 3d. has been written off as depreciation. This leaves a surplus on the year's operations of £16,276. 11s. 8d., from which £3,553. 19s., the sum at debit of profit and loss account brought forward from last year has to be deducted, which leaves £12,722. 12s. 8d. The revenue has increased by £28,181, while the working charges have only increased £10,982 The cost of generation and distribution shows a slight decrease in proportion to the quantity of electricity generated. Owing principally to economy in fuel and repairs the balance on the year's ordinary working is £60,993, as compared with £45,222 last year. The capital expenditure during the year amounts to £125,114. 18s. 10d., making the total capital expenditure as at May 31. 1905, after deduction of the depreciation noted above, £1,244 162. 12s. 10d. There is a noticeably large sale of current for power. The favourable results of the year's operations have justified the committee in proposing a substantial reduction in the charges for current used for private and stair lighting purposes, and the rates have been reduced from 6d. and 1d. on the maximum demand system of 3½d. for the first two hours and 1d. thereafter. For stair-lighting purposes the charge has been reduced from 25s. to 15s. per annum, while the charges for current for motive power purposes remain as last year. The quantity of electricity sold to private consumers during the past year was 16,642,253 units, as compared with 13,604,119 units during the previous year, being an increase of 22·36 per cent.

York.—Mr. C. A. Midgley, the city electrical engineer, in his annual report remarks that the income has expanded normally, but the expenditure of the past year has been heavy owing to the starting of new plant and the running of the old station without the condenser for eight months. He expresses every confidence that the current year will be a satisfactory one. The additional number of lamps connected to the mains during the year amounted to 9,819 8-c.p. lamps, making the total number connected 63,293. About 904,000 units were sold during the year, as compared with 776,542 units in the previous year, being an increase of 18 per cent. The revenue from the sale of the 904,000 units was £10,704, which works out at 2·84d. per unit sold. This is the highest rate received for the last three years. The income per unit for the year ending March 31, 1903, was 2·73d., and for the year ending March 31 1904, 2·76d. per unit. The gross profit was £5,021, being equal to a yield on the capital of the undertaking of 3¾ per cent. This figure is practically the same as the committee had achieved in previous years, but the increased interest and sinking fund account this year is £6,850, as compared with £3,799. 4s. 3d. in the year ending March 31, 1904. The number of motors now connected to the mains is 147, with a total horse-power of 660. This shows an increase in the year of 37 motors, with an increased horse-power of 130. The units sold under this section amount to 230,677, against 184,427 in the year 1903 4, being an increase of 25 per cent. The capital expenditure on motor letting is £4,960, and the income received from the rent of motors £460 per annum. The income derived for current power is approximately £100 per month, making the yield on the motor-hiring scheme 36 per cent. The income received from the sale of current for motors and the rent for the loan of motors will more than pay the coal bill for the whole of the station. The number of consumers now connected to the mains is 558, having increased from 470 in the previous year, being equal to an increase of 19 per cent. The maximum load on the station has increased from 661 kw. to 810 kw., being an increase of 24 per cent. The capacity of the plant is 1,860 kw., which leaves a sufficient margin without any extension for the coming winter. The first part of the alterations in the arc lighting is now completed, and there are now 27 Gilbert lamps put up in the centre of the city in the place of the old pattern lamp, and the improvement is admitted on all hands to be very great. The destructor during the past year has destroyed 10,657 tons of refuse, compared with 8,664 tons in the previous year. This plant has suffered very severely in the matter of repairs, and sufficient steam has not been procurable for carrying out the requirements of the department. There has not been a stoppage of the supply of electricity in the city during the last 12 months, and only one accident of a serious nature amongst the employés.

Bristol.—We extract from the accounts of the electricity department for the year ending March 25, 1905, as follows: The number of consumers on March 25, 1905, was 2,677, being an increase of 283 during the year. The total connections to the mains are equivalent to 274,166 30-watt lamps (as compared with 234,098 at the corresponding period of last year), made up as follows—viz: 79 886 taking energy at the power rate, 185,837 taking energy at the lighting rate, 8,383 representing the public street-lighting—this being an aggregate increase equivalent to 40,068 lamps, as follows: power connections, 22,651; private lighting, 17,411; public lighting, 105. The number of units sold was: private lighting, 2,400,392; power, 1,758,911; public lighting, 838,056—a total of 4,997,359 units; being an aggregate increase of 697,855. The use of electric motive power has continued to increase, the total units sold showing an increase over the previous year of 534,235. The gross receipts amounted to £59,687. 6s. 8d. and the gross expenditure to £31,935. 10s. 11d., leaving a gross profit of £37,751. 15s. 9d. available towards payment of dividends on stock and interest on loans and repayment of money borrowed, which amounted to £17,167. 19s. 4d. and £9,722. 18s. 3d. respectively. The net profit is £13,269. The total capital expenditure to March 25 last was £590,983, and the mortgage debt £499,240 after paying off or in stock redemption fund the sum of £74,840. The balances at credit of reserve fund and of depreciation and contingency account were £10 000 and £6,000 respectively, and £951 for unappropriated funds were carried forward. The following figures show that the number of consumers connected, etc., were: 1904 5, 2,677 (1903-4, 2,394); increase during year, 233 (297); equivalent in 8-c.p. lamps connected to date, 274,176 (234,998); added during year, 40,078 (51,964); number of units sold, 5 217,528 (4,299,504); revenue from lighting, £45,531 (£42,933); revenue from power. £9 084 (£6,634); revenue from public lamps (energy only), £3,918, (£7,317). Coal and other fuel in 1904 5 cost ·412d. (1903-4. ·59d.); oil, waste, and water, ·047d. (·05d.); wages of workmen, ·290d. (·30d.); repairs and maintenance, ·190d. (·17d.)—making a works cost of ·959d. (1·11d.). Rents, rates, and taxes absorbed ·158d. (·16d.); and management, salaries, office and legal expenses, and insurance, ·251d. (·31d.)—making the total cost 1·379d. (1·58d.). The maximum charges for private lighting during 1904 5 were 5d. and the minimum 2·33d., and those for private power, 1·5d. and ·83d. Mr. H. Faraday Proctor, the city electrical engineer, says with regard to fuel that last year he was able to report that the coal bill per unit sold had been reduced by 10 per cent., but the coal bill per unit sold has been reduced by a further 25 per cent., and each of the other items show a small reduction, the net result being a reduction in the total cost of generation and management from 1·58 in 1904 to 1·38 in 1905, being a reduction of over 12¼ per cent.; and whilst the average price obtained has fallen from 3·31d. in 1904 to 3·11d. in 1905, the net profit after payment on account of redemption of capital and interest on capital, amounts to rather more than ½d. per unit, being greater than that of any year since 1898, at which time the price charged was 6d. The second instalment of the works which was erected in the year ending March, 1904, has been completely equipped as regards the boiler-house portion, and in the engine-room the machinery foundations are completed and the auxiliary plant in place. Of the main generating plant, one set of 600 kw. will be supplied by Messrs. Siemens Bros. and Messrs. Parsons, and one set of 750 kw. entirely by Messrs. Parsons. These two sets will give alternating current for general lighting supply. Two remaining sets, each of 1 000 kw., are being supplied by Messrs. Willans and Robinson in conjunction with Messrs. Dick, Kerr, and Co., the whole of the before-mentioned machines being steam-turbine sets The last-mentioned will generate three-phase currents at a pressure of 6,000 to 6,600 volts (the existing high-tension alternating currents being generated at a pressure of 2,000 volts). These will be the largest machines yet installed by the department and will be used for running the motor-generators at Temple Back works and at other sub stations, and will also supply three-phase current in any outlying districts, where the distance from the generating station is too great to allow of economical transmission at the pressure of 2,000 volts. The four new boilers are of the same type as hitherto used—viz., Babcock and Wilcox water-tube boilers, working at a steam pressure of 200lb., and equipped with superheaters supplementing the natural temperature of the steam by an additional 200 deg. F. Each of these boilers has an evaporative capacity of 18,000lb. of water per hour when using a local slack coal; the heating surface of each boiler is 5,160 square feet, as compared with 4,784 square feet and 4,020 square feet heating surface, being the size of the respective instalments of boilers hitherto put in in these works.

PROVISIONAL PATENTS, 1905.

JULY 3.

13633. Improved central exchange telephone systems. Bertil Brander, The Deutsche Telephonwerke, Zeughofstr. 7, Berlin, Germany.

13638. An arrangement for raising electric tramcar windows. Clarence Adolphus Cass, York-street, Bury, Lancs.

13653. Improvements in or relating to liquid controllers. William Sylvanus Shields and William de Forest Jones, 111, Hatton-garden, London.

13676. Improvements in point shifters for tramways and the like. George Dudley Aspinall Parr, Norfolk House, Norfolk-street, Strand, London.

13677. Improvements in electric condensers. Reginald Aubrey Fessenden, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13678. Improvements in signalling by electromagnetic waves. Reginald Aubrey Fessenden, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13679. Improvements in aerials for the transmission and receipt of electromagnetic wave energy Reginald Aubrey Fessenden, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13681. Improvements in regulating mechanism for arc lamps. James Brockie, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13682. Method and apparatus for the manufacture of electrical condensers. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers Southampton-buildings, Chancery-lane, London. (Siemens und Halske, Akt.-Ges., Germany.) (Complete specification.)

13688. Improved construction of electric switch. Carl Schmahl, 175, Fleet-street, London.

Digitized by Google

13688. Improved method of braking cars propelled by alternating-current electric motors. Siemens Bros. and Co., Limited, and Francis Lydall, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

13689. Improvements in the method of deviating or drawing out electric arcs or electric discharges, and also apparatus for chemical decomposition and combination of gases, for instance air, by means of such deviated or drawn electric arcs or electric discharges. Richard Core Gardner, 173, Fleet-street, London. (Johan Jetmund Thoresen and Filip Tharaldsen, Norway.) (Complete specification.)

13690. Improvements in electric furnaces. Paul Girod, 24, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, July 4, 1904, being date of application in France.) (Complete specification.)

13696. Improvements in alternating-current electricity meters. William Hamilton and Ferranti Limited, 18, Southampton-buildings, Chancery-lane, London.

13706. Improvements in and relating to electric motors for use with either alternating or continuous currents The Allgemeine Elektricitäts-Ges., 83, Cannon-street, London. (Date applied for under Patents Act, 1901, July 4, 1904, being date of application in Germany.) (Complete specification.)

13707. Improvements in and relating to fluid-pressure brake systems for railway and tramway vehicles and the like. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States. (Complete specification.)

13708. Improvements in and relating to dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Allgemeine Elektricitäts-Ges., Germany.) (Complete specification.)

13709. Improvements in systems of motor control. Frank Edwin Case, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, July 2, 1904, being date of application in United States.) (Complete specification.)

JULY 4.

13713. Improved means for electrically or otherwise signalling from one part to another of a theatre, building, ship, and the like. Edward Broadley, 26, Paradise-street, Birmingham.

13779. Improvements in apparatus or appliance for more readily adjusting the trolley wheel of arm of electric cars to the overhead wires. Thomas Frederick Stidolph, 3, Malden road, Colchester.

13782. Inverted incandescent lamps. John Thomas and Arthur Edward Podmore, 53, Hanley-road, Stroud Green, London.

13794. Improvements in armatures for magneto-electrical machines or electric dynamos or motors. Felipe Saldaña, 72, Cannon-street, London. (Date applied for under Patents Act, 1901, July 5, 1904, being date of application in France.) (Complete specification.)

13796. Improvements relating to electrical signalling and controlling devices. Lorenz Kottmair and Rudolf Zwack, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

13808. Improvements in the electrolytic production of metallic sheets, tubes, wire, strip, or the like. Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

13815. Improvements in or connected with safety fuses for electrical conductors. William Oke Manning, 40, Chancery-lane, London.

13816. An electromagnetic reversing gear. Frantz Jensen, 40, Chancery-lane, London. (Complete specification.)

JULY 5.

13828. A new or improved receiving instrument for wireless telegraphy. Charles Vernon Boys, 66, Victoria-street, London.

13842. Improved trolley head for electric tramway cars. Henry Norris Davidge, 6, Piccadilly-mansions, Piccadilly-circus, London.

13856. Improvements in or relating to the electrical steering of ships. Bernard Parker Haigh, 111, Hatton-garden, London.

13874. Improvements in electrical transmission apparatus for causing the movements of any mechanism to be exactly repeated upon distant mechanisms. Everahed and Vignoles, Limited, and Sydney Everahed, 1, Queen Victoria-street, London.

13876. Improvements in or connected with anodes. Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

JULY 6.

13909. An electric purifier for use in milling or any other trades to which it may be applied. John Lawson Lawson, 34, York place, Edinburgh.

13913. An apparatus for the application, control, and measurement of X-rays. Alfred Ernest Dean, 82, Hatton-garden, London.

13919. An improved switch and rheostat controller. Evelyn Banks, 70, Russell-street, Bolton, Lancs.

13918. Improvements in electrical junction boxes, switch boxes, ceiling-rose boxes, and the like. James William Brooks, trading as the Walsall Hardware Manufacturing Company, and Albert Edward Read, 128, Colmore-row, Birmingham.

13954. Improvements in and relating to electrical testing devices. George Harrison, 11, Southampton-buildings, Chancery-lane, London. (The Electric Railway Improvement Company, United States.) (Complete specification.)

13958. Improvements relating to transformers and dynamos. August Dr ssner, 7, Southampton-buildings, Chancery-lane, London.

13964. Improvements in apparatus for automatically opening or breaking an electric circuit or circuits and system of wiring in connection therewith. Percy Fullerton Corkhill, 6, Lord-street, Liverpool. (Complete specification.)

13973. Improvements in motor-driven machines. The British Thomson Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

13974. Improvements in fuse boxes. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

13975. Improvements in semaphore signals. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

13976. Improvements in electrical indicating instruments. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

13977. Improvements in electric fuses or cut-outs The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

JULY 7.

14000. An improved method of cutting off electricity either automatically or at will. William Arthur Jones, 10, St. George's-crescent, Liverpool.

14013. Improvements in or connected with electrical distribution or junction boxes. Reginald Sydney Downe and Arthur Smith Black, 15, Water-street, Liverpool. (Complete specification.)

14033. Improvements in mercurial vapour electric lamps. Francis Harrison, 157, Grange Park-road, Leyton, London.

14047. An improved electric battery for use in treating the human ear. Augustus Royel, 11, Southampton-buildings, Chancery-lane, London.

14050. Improvements in electric quantity meters of the electrolytic type. Edward Jesse Piper, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

14059. Improvements relating to the trolleys or current conductors of overhead-driven tramways and the like. Thomas Cowburn, 72, Cannon-street, London.

JULY 8.

14104. Improvements in and relating to relays. Hugo Mosler, Zürich-Langnau, Switzerland.

14126. Improvements in convertible cars. Robert George Dickson 4, South-street, Finsbury, London. (Michael Power, Canada.)

14129. Improvements relating to primary batteries. Caesar Gustav Luis and Francis Bothomley Lark, 7, Southampton-buildings, Chancery-lane, London.

14131. Improvements in the construction of sound-proof telephone cabinets and other chambers. Reginald Haddan, 31, Bedford-street, Strand, London. (Akt.-Ges. Industrie für Holzverfuog, Germany.) (Complete specification.)

14141. Improvements in electric signalling. Edward Richard Ernest Rotter, 18, Southampton-buildings, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published July 27.

1904.

12346. Electric switches. Zani.

14829. Electro-medical apparatus for the curative treatment of disease. Braun.

14876. Life-saving guards for tramway cars and the like. Ellis.

15283. Charging of electric accumulators for self-propelled vehicles. McLaren.

15289. Relays for direct-current automatic circuit breakers. Garrard, and Ferranti Limited.

15290. Electrical measuring instruments. Garrard, and Ferranti Limited.

15778. Contact stud and switch for use with surface-contact systems of electric traction. Griffiths and Bedell.

16326. Apparatus for use in the teaching of electric, telegraphic, and other signalling by means of the Morse or other similar codes. McDonald.

16846. Time element devices applicable to electric circuit breakers and other apparatus. Statter.

NOTES.

Wireless Telegraphy in France.—Whether *propter hoc* or only *post hoc* can only be conjectured, but M. de Branly's lecture in Paris on the wonders actual and possible of wireless telegraphy has been rapidly followed by remarkable results. Up to the present week the system had been steadily ignored by the Government. Now it is announced that the Minister of Commerce has decided to organise a service, and has requested his colleagues of War and Marine to establish with the least possible delay three coast stations, one at Toulon, one at Cherbourg, and one at Bizerta.

Water Power in India.—The Municipal Board of Mussoorie have in hand a large scheme by which electric energy will be obtained for lighting and use in connection with their waterworks. The three-phase plant needed will be driven by water power, and will in turn drive a certain number of pumps for the water-supply scheme. Complete specifications for the equipment have been drawn up by Mr. C. H. Shanan, A.M.I.C.E, and tenders are to be returned to Mussoorie by Oct. 23. They are to include the supply and erection of the water-power plant, the alternators, exciters, switchboards, transformers, motors, and the complete line equipment. The work will, we trust, be placed with an English firm.

Private Tramcars.—Considerable interest has been aroused in London by the fact that the Duchess of Northumberland recently engaged private electric tramcars to convey her guests to Sion House, Isleworth. It may be pointed out that "special tramcars" are not an innovation, and that one can be chartered to Hampton Court and back for three guineas. London is very far behind, however, in this respect. Private cars are common in other parts of the world. Even in Jamaica one can engage an electric "social" car for a whole evening. It has the run of the whole system, extending some eight miles out into the country, and only costs 10s. It is marked "private," and is often brilliantly lit up with coloured lights.

Wireless Telegraphy to Iceland.—The officers of two steamers which arrived at Leith from Iceland on Saturday report that about the 26th of last month the island was put into communication, partly at any rate, with the outer world by means of the Marconi system of wireless telegraphy. The communication is as yet only partial, as the apparatus at Reykjavik can only receive messages, but it is possible that a transmitting instrument will shortly be added to the equipment of the Reykjavik station. Should the experiment be satisfactory to those concerned, the wireless service may, for some considerable time at any rate, serve instead of the proposed submarine cable, the laying of which would be very expensive in proportion to the use that would be made of it. The wireless messages, the most of which come in the first instance from Denmark, are sent from one of the Marconi stations in the North of Scotland.

Decimal Weights and Measures.—Early this year Sir Edward Fithian, the secretary of the Association of Chambers of Commerce, sent a resolution of the association asking the Board of Trade to authorise weights of 20lb., 10lb., and 5lb. as aliquot parts of the cental, to which Lord Salisbury has replied as follows: "With reference to your letter of March 14 last, in which you suggest that new denominations of weights of 20lb., 10lb., and 5lb. should be legalised for use in trade, the Board of Trade have given careful consideration to the representations which have been made, and they are prepared to assent to the application. Steps will, therefore, be taken for the preparation of standards of the same octagonal form as the present 50lb. weight." The chambers consider that this concession will save time, labour, and expense, as the 50lb. weight as done already. It is amusing to find that the daily papers refer to this step as if it was part of the metric system of weights and measures.

Sir Humphry Davy Memorial.—There was an interesting ceremony at Clifton, Bristol, on Friday, when Signor Marconi unveiled a tablet which the Clifton Improvement Association proposes to place on 3, Rodney-place, Clifton, where Sir Humphry Davy, Dr. Thomas Beddoes, Thomas Lovell Beddoes, and his aunt, Maria Edgeworth, formerly lived. The ceremony, which attracted a large company, took place in the Grand Spa Pump-Room. Mr. Lewis Fry was in the chair, and welcomed Signor Marconi to Clifton, and afterwards gave some interesting details of the lives of Sir Humphry Davy, Dr. Thomas Beddoes, Thomas Lovell Beddoes, and Maria Edgeworth. In performing the unveiling ceremony, Signor Marconi said that the name of Sir Humphry Davy would ever live in the minds of men, for he was more than a genius. Few men had ever combined with such marked success the qualities of scientist and philosopher. It was appropriate that Clifton should, by means of the tablet, perpetuate the name of Humphry Davy, for it was here that he entered upon his public career.

London County Council Conduit System.—The conduit system of the London County Council has now had a fairly long trial. The results of experience with the first section laid down have pointed to improvements in details which are now to be embodied in the further lines to be converted. Under the several Tramway Acts the Council has to get the approval of the Board of Trade to the system employed, and each of the road authorities has also a voice in the matter. From a description laid before one of these authorities for approval we glean the following details as to the principal differences between the proposals of 1902 and 1905:

	1902.	1905.
Rails	102lb. per yard lineal.	105lb. per yard lineal.
Fishplates	54lb. per pair.	57lb. per pair.
Slot rails	⅝in. apart.	1in. apart.
Boxes for slot rails	2ft. 6in. long.	3ft. 6in. long.
Insulator boxes	1ft. square.	1ft. 4in. by 1ft.
Inspection boxes for drainage	19in. by 12in.	18in. square.

The increased width of the slot is the only objectionable alteration, but we believe this to be a necessity. The other changes give increased facilities for inspection and repairs or increased strength, and will be universally approved.

Telephone Agreement. — On Monday last the question of the future position of the staff employed on the telephone system as compared with that under which the company now employed them was discussed before a Select Committee of the House of Commons. Mr. Babington Smith, secretary to the Post Office, was recalled, and gave evidence with reference to claims put forward by the staff of the company. He said they were asking for continuity of employment when the transfer took place. At present their services could be dispensed with by the company at a month's notice, and he did not think there was much fear, having regard to the rapid growth of the service, that their prospect of continued employment would be worse under the Post Office than under the company. Assurances had been given by the Postmaster-General to deputations that the staff would be taken over *en bloc*, but that did not give a guarantee to individuals which would create a vested interest and enable them to claim compensation for loss of office. Those placed on the established staff (and they would be the large majority) would have a more secure tenure than under the

Digitized by Google

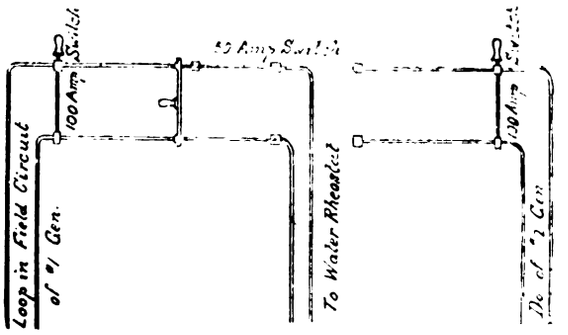
company, and those on the unestablished staff would be in no worse position than they were now.

The Manchester Mains Case.—In our issue for March 31 we reported the case of Midwood *v.* the Manchester Corporation. The judgment was given against the Manchester Corporation. The facts of the case are briefly as follows. A fault occurred on the Manchester mains, and this was burnt out electrically, as is the usual practice in most supply systems. Unfortunately, in burning out the fault the fire spread to the premises of the plaintiff, and damage estimated at £677 was caused. The Corporation appealed against the decision, but have again had the verdict given against them by the Court. The defence was that, as the Manchester Corporation had complied with the requirements of the Board of Trade, they should be relieved from the liability in question. Under the provisional order, however, it is provided that "nothing in this order shall exonerate the undertakers from any indictment, action, or other proceedings for nuisance in the event of any nuisance being caused by them." We commented on the case in our issue for March 31, and need only repeat here that the Manchester mains have been carefully designed and laid, and that, while justice has been done, it is adding insult to the damages when the mains are termed nuisance. It is only right that a municipal undertaking should be responsible for any damage it may do in the same way as other private undertakings are.

Tramway Speeds.—In the earlier days of electric traction the increased speed of electric tramcars over that of the horse cars which they replaced resulted in numerous accidents. There were in consequence a number of complaints that the speed of electric cars was excessive. As we pointed out then, the matter was rather one of educating the people to avoid crossing the roads without exercising ordinary care. The continued use of the tramways has been followed by a marked decrease in the number of accidents, and we are pleased to see that the restriction in maximum speed to eight miles per hour is being altered by the Board of Trade in many places. Amongst the most recent moves in this direction is one on the part of the Deptford Borough Council. The General Purposes Committee of this Council have instructed their mayor to represent to the Board of Trade that, in their opinion, the County Council tramcars should be allowed to travel at the highest rate of speed consistent with the safety of the general public. The Board of Trade have commissioned Lieut.-Colonel Yorke to inspect the various routes and to report to the Board, the County Council having urged that, in view of the fact that the cars are to be equipped with special brakes, and that the drivers have now acquired greater skill, a higher rate of speed should be allowed than was at first thought desirable. As in the case of motorcars, the safe maximum speed is determined by the braking facilities, and these, as pointed out, are very ample in modern tramway practice.

Heating of Enclosed Conductors.—This was one of the subjects brought before the Montreal convention of the Canadian Electrical Association last month. For the past three years McGill University has been the scene of some research work which is of great importance and interest to the electrical world, and which is revolutionary in its character. This is an investigation into the heating of enclosed conductors, and in the conclusions which are being reached it is being shown that the present information on the subject is far from complete, and existing tables are consequently quite incorrect. This work was to have been described to the convention by Prof. R. B. Owens, but in his absence Prof. L. A. Herdt discussed the subject. The paradox has been established that the thicker the insulation on a conductor the more current is required to cause a given rise in temperature. Though this seems absurd at first, it is explained by the fact that the thicker insulation has a greater radiating surface. If two small wires are placed in a small duct they can carry 30 per cent. more current than if they are in a large duct, for in the large duct there is no chance of radiation except where the wires touch the duct, and still air is one of the worst conductors of heat. Consequently, when laying out a system for 10deg. rise, it is necessary to place the wire with as thick insulation as possible, and in as small a conduit as possible. In experiments with bare wire in still air, the results tally very well with the tables given in the standard text-books, but as soon as wires are placed in conduits the old formulas do not apply at all. So far, these experiments have been conducted for rubber insulation only.

Paralleling Generators.—A method of obviating the disturbance in the exciter speed and voltage that ensues when one generator is thrown in parallel with another having the same source of exciting current, has been contributed to the "Wrinkles" department of the American National Electric Light Association by Mr. G. Hartman. Another objection that arises under the conditions mentioned is that the second generator, or generators, is subjected to the sudden switching on of a large percentage of the full load. The contrivance recommended by Mr. Hartman is illustrated in the accompanying diagram, which



we reproduce from the *Western Electrician* of Chicago. A water rheostat is connected to a double-throw switch, so that it may be inserted in the field circuit of either of the two generators or be short-circuited. This results in a very gradual rise in voltage from zero to normal, and a gradual decrease from normal to zero in starting up, or closing down, a second generator, line and transformer set. The disturbance is thus eliminated from the first generator, and there is a minimum strain on the second outfit.

Municipal Wiring in London.—The London County Council (General Powers) Bill this year again contained provisions which would, if passed, have authorised the municipal authorities within the Council's area to carry out wiring work. This clause was also inserted in the 1903 Bill, when it was strongly opposed by the Electrical Contractors' Association. In 1903 the clauses were struck out by the House of Commons. In spite of strenuous opposition by the above association the House of Commons passed the clause this year, but it has failed to get through the House of Lords. The chairman of the committee was the Duke of Northumberland. It was urged on behalf of those who supply fittings and general electrical installations to private consumers that they would suffer great loss and hardship if the clauses were accepted. The petitioners contended that the nature of municipal competition with private traders was grossly unjust and different in every respect from ordinary trade competition, and that it was unfair to use the ratepayers' money for the purpose of

Digitized by Google

injuring other ratepayers by such trading. The Duke of Northumberland said it would not be necessary to call witnesses in support of the petition against the provisions, which would be struck out of the Bill. The Electrical Contractors' Association are to be congratulated on the success of their opposition, and we think the decision is one which is also in the interests of the electrical supply undertakings. Any such undertaking has everything to gain from the efforts of wiring contractors in the district to obtain work, and by competing with them it immediately reduces the number and activity of canvassers tending to increase supply business. The slight gains from municipal wiring in certain cases do not warrant the risk which any department of the kind must necessarily involve.

Heavy Electric Traction.—The engineering problem of converting steam railways over which a heavy traffic is carried over a considerable distance is one which, although treated of by many engineers, has yet to be finally solved. The many debates on the subject which have taken place before various engineering institutions in this country show that the financial question is the one to which most consideration has to be given. At the recent meeting of the American Institute at Asheville, Mr. Carl de Muralt contributed a paper on the subject. In this he dealt more particularly with a main-line system, taking as an example a line 175 miles long in one direction with a 49-mile extension for mineral traffic in another. He assumed that there were only 16 stations in the 175-mile length and four stations in the other. The traffic on the line was not as heavy as we are used to in this country, as it was assumed there were only eight trains per day in each direction. The question as to the most economical system to be used is then gone into most carefully. In each of the four systems on which information is given, high-tension transmission by either three-phase or single-phase alternating current is employed. The chief difference between them is in the matter of the equipment on the trains, and consequently in the sub-station machinery. In the first system the continuous-current series motor on the locomotive would be fed from sub-stations much in the same way as has been done in the most recent electrification of suburban lines in this country. The second system involves the use of three-phase induction motors on the locomotives; hence only static transformers are needed in the sub-stations. The third system would employ a single-phase alternating-current motor on the locomotive, and in the fourth a reversion is made to continuous-current motors fed from motor-generators carried on the locomotive. Actual figures are given for the first two systems, but the author confines himself to general conclusions when making comparisons between these figures and the results to be obtained by the latter two systems. We have not space at our disposal to follow his figures in detail, but his conclusions are all in favour of the three-phase alternating-current system. This he shows from his estimate to be cheaper to instal and to operate than the continuous-current system. He claims for the three-phase induction motor that it is at least equal in every respect to the continuous-current series motor and superior to the latter on a number of important points. The increased cost and inconvenience of having two overhead wires instead of one has still to be considered. The author states that in street railway systems the motor repairs cost anything from four to ten times as much as the repairs to the line. He concludes, therefore, that any slight increase in cost of supervision due to the two overhead wires would be small compared with the saving which would be effected by the use of three-phase motors. Where the line is through a hilly country stress is laid on the advantage of the three-phase motor as being able to return power to the overhead conductors when the trains are descending grades.

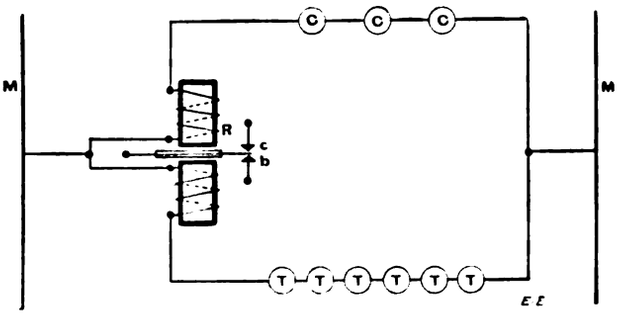
Double Trolley Wires in Cuba.—We understand that the General Electric Company of America has recently secured a large order for a complete network of inter-urban electric railway lines having Havana as their centre. The system will consist of a central power-house in Havana and eight outside sub-stations, together with line material for about 125 miles of track and rolling-stock for passenger and freight service over the entire system. The power-house in Havana will furnish 5,000 kw. of 19,000-volt, 25-cycle, three-phase current, generated by two 2,000 kw. generators and 1,000-kw. Curtis steam-turbine generators at 2,200 volts, and stepped up through air-blast transformers to the line voltage. The transmission lines will parallel the various lines of the railway to the sub-stations, where step-down transformers supply low voltage to rotary converters furnishing 600-volt direct current to trolley lines and feeders. From Havana one branch will run south-east to Rosario, a distance of about 40 miles. Sub-stations will be located at Cuatro Caminos, Lomas de Candela, and Providencia. A second line will run from Havana 17 miles south to Bejucal, with a sub-station on the line at Santiago de las Vegas. A third line, running south-west from Havana to Mariel, will have a length of 37 miles, and branch lines running north and south to El Carmelo, Santiago de las Vegas, and Tuira de Melena, amounting to about 30 miles in addition. Sub-stations on the line to Mariel will be placed at Marianao, Hoyo, Colorado, and Tuanajay, and at San Antonio Melena. The rolling-stock for passenger service will consist of 24 30-ton cars, seating 50 passengers and equipped with four motors geared for a maximum speed of 40 miles per hour. The freight service will be handled by 10 40-ton locomotives equipped with four motors geared for a speed of 17 miles per hour when hauling a 300-ton train. The entire system will have double overhead trolleys both in Havana and on the interurban lines. The high-potential transmission lines will be designed for a future potential of 30,000 volts to provide for extensions. The transformers in the Havana power-house and in the sub stations are also suitable for use on the increased potential. It is expected that the entire system will be in operation inside of 18 months, and that portions of it will be giving service before that time. As pointed out in the *Electrical World*, the novel feature in the equipment is the use of the two trolley wires in order to avoid the earth return. This system was at first proposed for the London United Tramway system in order to avoid disturbing the Kew Observatory. It was not installed, however, and the magnetic instruments were removed from Kew instead. In the States the system has been used at Cincinnati and one or two other places, but we understand that the tramway managers in these places would be glad to change over to the single trolley and track return if they were allowed to do so. The line voltage in Cuba is to be 600, and although a good deal of the ground may be swampy in character, we think that the single trolley and track return would have given successful results.

High-Potential Surges.—At the recent meeting of the American Institute of Electrical Engineers at Asheville, Dr. C. P. Steinmetz presented a paper on "High Power Surges in Electrical Distribution Systems of Great Magnitude," and Mr. P. H. Thomas followed with a paper on "The Rise of Potential on Commercial Transmission Lines due to Static Disturbances caused by Switching, Grounding, etc." In the course of the joint discussion, reported in the *Electrical World* of New York, Dr. Steinmetz stated that there existed undoubted evidence that the arc is self-rupturing—that is, it mends itself in the

Digitized by Google

extreme suddenness, and the potential at mending may be greater than the striking voltage. After the arc mends itself it immediately ruptures again, and it then becomes an oscillating arc. The frequency of oscillation is determined by the capacity and the inductance, and not by the frequency of the E.M.F. If a condenser and an induction coil be placed in series with each other, by means of a spark gap an oscillating current may be produced in the system even when the supply E.M.F. is continuous. One of the conditions under which an arc becomes self-rupturing is that the voltage exceeds the striking distance of the arc, and that the flow of current in the arc causes the potential difference at the arc to drop practically to zero, and remain at zero a very short time after the arc has ruptured. Therefore, in experimenting with the arc in a circuit containing resistance in series and no capacity, the arc is not oscillating or self-rupturing, and cannot be made so, because simultaneous with the mending of the arc the voltage rises and so prevents the arc from rupturing. When high-frequency oscillations are produced by shunting the arc with capacity and inductance in series the length of time the arc exists is the time required by the charging current of the condenser to heat the air sufficiently to cause an explosion, and also to discharge the condenser and allow the voltage to drop to zero. The period of the zero current is the time required for the condenser to be recharged by the voltage from the inductance. The frequency of the oscillating arc can, therefore, be varied by varying the inductance, the capacity, or the length of the spark gap, all three elements entering into the determination of the frequency. The phenomena become more complicated where, instead of localised inductance and capacity, there are distributed inductance and capacity as in cables. In favour of the explanation of the oscillating arc here given may be stated the fact as observed by Mr. Stott, that short-circuits were always preceded by grounds on the lines and by static displays. If the explanation is correct, and if the E.M.F. reaches 100,000 volts, and the current is as large as 9,000 amperes, there is no possibility of insulating and protecting against these surges. The only course to pursue is that taken by Mr. Stott in avoiding the cause of the surge, and eliminating the continued occurrence of the spark discharge between the conductor and ground by disconnecting with the regular automatic circuit breaker that particular cable in which the spark first appears before the damage can spread farther and produce high-power low-frequency surges.

Potential Regulation of Carbon and Tantalum Lamps.—Messrs. A. E. Kennelly and S. E. Whiting describe in the *Electrical World* of New York an interesting device for regulating voltage based on the different behaviour of carbon and tantalum lamps under varying voltages. It is well known that the resistance of a carbon-filament incandescent lamp falls very markedly as the current through it increases. Thus, a 120-volt, 16-c.p. carbon lamp, which has a resistance of 600 ohms when cold, will have a resistance of about 300 ohms when at normal incandescent voltage. A 110-volt tantalum lamp, on the other hand, which has a resistance of 50 ohms when cold, may have a resistance of 300 ohms when at normal incandescent voltage. In each case the most rapid change of resistance takes place in the initial stages of voltage and current application. Between half voltage and full voltage the changes in resistance are relatively small. One device proposed by the authors is the use of a Wheatstone bridge with carbon lamps in one arm and tantalum lamps in another. In the place of the usual galvanometer a polarised relay or other magnetic mechanism would be employed to close a subsidiary circuit which would regulate the main voltage. An alternative plan is that shown in the illustration herewith, where a differentially polarised relay is used. In this arrangement the circuit from the mains, M M, splits through the coils of this relay, passing on one side through the carbon-filament lamps, C C C, and on the other side through the tantalum-filament lamps, T T T. The lamps are so chosen, or the resistances of their respective paths so adjusted, that the two branch currents have equal strength at normal voltage between the mains, thus leaving the relay in balanced condition—*i.e.*, with zero excitation. If now the main voltage should rise, the resistance of the carbon branch will diminish and that of the tantalum



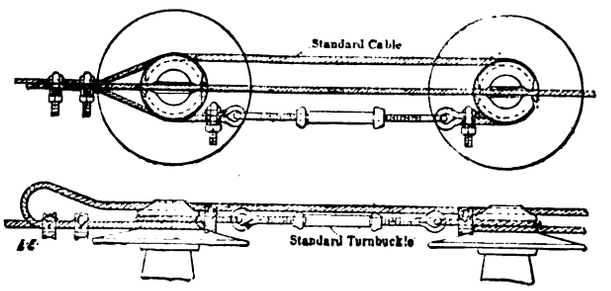
branch will increase, thereby upsetting the balance in favour of the carbon branch current, and urging the tongue of the relay against the stop, *c*. On the contrary, if the main voltage should fall, the differential balance would be upset in the opposite direction and the tongue of the relay urged against the opposite stop. This action of the relay might likewise be invoked to control the main voltage through mechanism actuated by local circuits from the relay. From actual trials made with an apparatus of this kind over a relay of the Western Union type the authors found that an increase of 0·6 volts—*i e*, from 120·4 to 121—was quite sufficient to operate the relay. There was a time lag of about a second in the operation of the relay, which appears to be due to the thermal effects outside the lamps. The device is an interesting utilisation of the different characteristics of these two types of incandescent filaments.

Lightning Protection.—At the recent Denver Convention of the American National Electric Light Association, an interesting discussion, of which an abstract appears in the *Electrical World* of New York, ensued on "Present Methods of Protection from Lightning and Other Static Disturbances." Referring to the water jet arrester used in California, Mr. Alex Dow stated that this was merely a leg of high resistance and of no inductance, and that it consumed energy continuously. The water jet might be used to good purpose in many high-tension transmission lines as special protection during thunderstorms in much the same way as in certain railway plants the tank arrester is switched on during thunderstorms. In conjunction with choke coils it would furnish a thoroughly reliable means of protection, though its use involves a loss of energy from 3 kw. to 10 kw., depending upon the voltage. Owing to information received since the report was prepared, the recommendation of two ground wires should be withdrawn in favour of the use of a single ground wire, which will do the work as well as two wires and be as reliable. No reliable information could be obtained concerning the horn arrester, but it seemed that the tail-piece is dispensed with entirely in many European plants. Mr. Dow advised the appointment by the association of a reporter to gather information on the subject of lightning protection and to report same to the association. In reply to a question, Mr. Dow said that flashing across storage battery terminals to ground has happened, the discharge being across the surface of the tanks. Mr. R. F. Hayward stated that in Utah there are

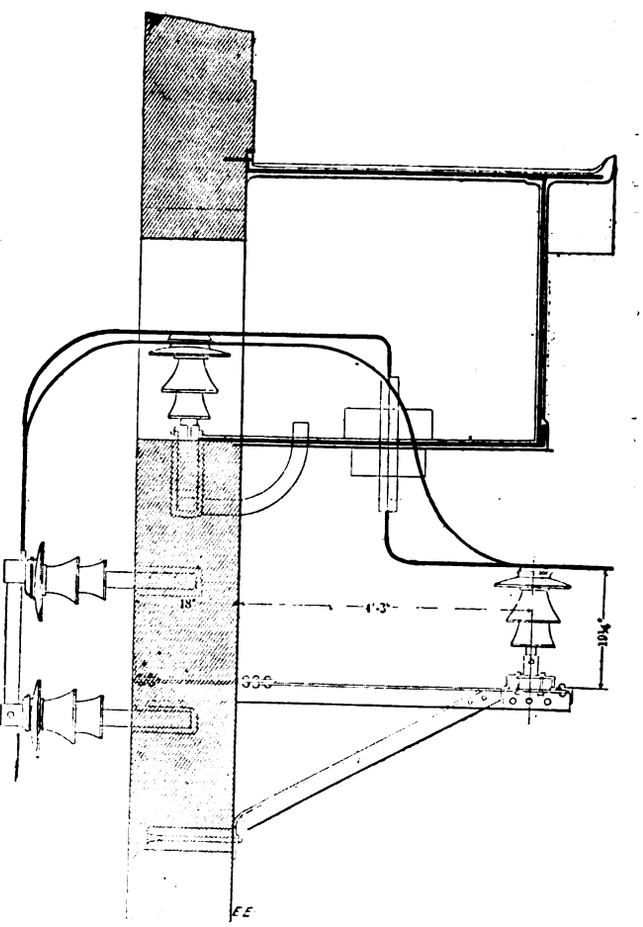
Digitized by Google

about 300 miles of 40,000-volt and 200 miles of 28,000-volt lines running in parallel, and scarcely any storm passed through the territory covered without striking something, either directly or inductively. He has come to the conclusion that the lightning protection should be spread all over the line in the form of lightning conductors. It is found that when a storm occurs it will generally strike the lines and split a number of poles, shattering all the insulators on one pole and puncturing a number of insulators on other poles. The effect is seldom found far from the point where the stroke comes, and if the stroke is near the power-house some apparatus is likely to be lost or terminals burned out. A number of transformers of the old air-blast type have been lost, but none of those with new windings which have replaced the old type, although in a recent storm some of the terminals were burned off. The arc will cross from terminal to terminal, jumping distances of five or six inches, and while this shuts down the plant for a moment, no other damage is done. Recent experience has shown that modern insulation, whether of the air-blast or oil type, is becoming very good and very high. Mr. Hayward considered that the ground wire should be placed on the line; if there is no ground wire on the line, one of the two circuits is grounded at each end of the line when a thunderstorm comes along. If a ground wire is above the other lines, it should be as far above as possible, for then the stroke will discharge to this wire and take the ground by a number of different paths, whereas if the ground is at the neutral point of the main circuit it is almost certain to cause an arc that will give a short-circuit, and these sudden short-circuits are the cause of setting up low-frequency waves which go into the power-house, pass through the choke coil, and are liable to break down the apparatus. Mr. E. P. Dillon stated that the Colorado Springs lines were particularly menaced by lightning. At present lightning arresters are liberally distributed at the various plants and sub-stations, but there are none on the line, since it is felt that the risk of having lightning arresters on the line was an offset to their advantage. He thought that a well-constructed ground wire would obviate some of the difficulties which have been met with. At three different times in the past two years the lines have burned out directly in the middle of a span, and not at the poles.

Niagara and Toronto Transmission.—In our last issue we gave some particulars of the new transmission lines which are being erected to convey energy from Niagara to Toronto. From further information appearing in the *Electrical World* we note the following details, which will interest those readers who have overhead line work to erect in this country. The three insulators carry the three conductors, for which circuits are placed at the corners of an equilateral triangle with 6ft. sides. The anchorage of the line wire at the terminal towers is carried out in the following way. Where the cables are secured before they pass into a terminal station, the three insulators for each cable are placed in a straight line with their centres 30in. apart. When a line cables reaches the first insulator of the three to which it is to be attached on one of these towers, it is passed round the neck of this insulator, and then secured on itself by means of two clamps that are tightened with bolts and nuts, as illustrated. The cable thus secured turns up and back over the tops of its three insulators, and goes to the terminal station. Around the neck of the insulator to which the line cable has been secured in the way just outlined, a short detached length of the regular copper cable with the parts of a turnbuckle at each end is passed, and this same piece of cable also passes round the neck of the next insulator in the series of three. By joining the ends of the turnbuckle and tightening it, a part of the strain of the line cable in question is transferred from the first to the second insulator of the series. In the same way a part of the strain of this same line cable is transferred from the second insulator of the series to the third or one nearest to the terminal station. From its insulators on a terminal tower each line cable passes to an insulator at the same level on a steel bracket outside of the terminal station. After leaving this insulator on the bracket, the



line cable turns up and goes through a bushing set in the bottom of a metal box or hood that is fixed on the outside of the terminal station above the steel bracket, as shown. Having reached the inside of this metal hood, the line cable makes another right-angle turn, and goes through the centre of a 40in. by 36in. opening in the brick wall of the terminal station. At the centre of this square opening the line cable is supported by one of the porcelain insu-



lators regularly used outside. The hood just mentioned is made of expanded metal covered with cement. From the line cable to the steel socket of the pin on the bucket the shortest distance through the air is about 17in., and this is also the distance from the cable to the metal hood. Between the line cable and the brick wall outside of the metal hood the distance is about 25in. At the upper outside edge of the hood there is a gutter that prevents the dripping of water on to the insulators and line cables below.

ROYAL COMMISSION ON LONDON TRAFFIC.

The first volume of the report of this Commission was issued on Monday last, and is to be followed by seven other volumes, which will cover the whole subject. The Commission appointed in 1903 consisted of Sir David Miller Barbour, K.C.S.I., K.C.M.G. (chairman); the Right Hon. Earl Cawdor; the Right Hon. Viscount Cobham; the Right Hon. Lord Ribblesdale; the Right Hon. Sir Joseph Cockfield Dimsdale, Bart., K.C.V.O., M.P.; Sir John Poynder Dickson-Poynder, Bart., D.S.O., M.P.; Sir Robert Threshie Reid, G.C.M.G., K.C., M.P.; Sir John Wolfe Wolfe-Barry, K.C.B., F.R.S.; Sir Francis John Stephens Hopwood, K.C.B., C.M.G.; Sir George Christopher Trout Bartley, K.C.B., M.P.; Sir George Stegmann Gibb; Mr. Charles Stewart Murdoch, C.B.; Mr. Felix Schuster; Mr. Lynden Macassey, M.A., B.Sc., LL.D. (secretary).

The Commission were commanded to enquire into the means of locomotion and transport in London, and to report: (*a*) "As to the measures which they deem most effectual for the improvement of the same by the development and interconnection of railways and tramways on or below the surface; by increasing the facilities for other forms of mechanical locomotion; by better provision for the organisation and regulation of vehicular and pedestrian traffic, or otherwise. (*b*) As to the desirability of establishing some authority or tribunal to which all schemes of railway or tramway construction of a local character should be referred, and the powers which it would be advisable to confer upon such a body." The Commission not merely took evidence, but by a special arrangement obtained expert and technical advice from the Advisory Board of Engineers which they appointed. One of the members of the Commission, Sir John Wolfe-Barry, K.C.B., undertook, without remuneration, to act on and preside over the Advisory Board, and they state they were fortunate to obtain the services of Sir Benjamin Baker and Mr. William Barclay Parsons, M.I.C.E., chief engineer to the Board of Rapid Transit Railroad Commissioners of the City of New York, who was well acquainted with London. The full report of this Advisory Board will appear in vols. vii. and viii., yet to be published, but the Commission have not endorsed all the recommendations of this Board.

The Commission's report covers much ground that is beyond the scope of our journal, but the following abstracts will show the general trend of the recommendations. After showing the need for further facilities for locomotion and the failure of rehousing schemes in the central districts, it is pointed out that the only difficulty in the way of completely reorganising London for purposes of locomotion is the question of cost. The ideal scheme is the construction of railways in London for purposes of long-distance urban traffic, and of railways radiating to the suburbs for purposes of suburban traffic, the railways both in urban and suburban localities being connected with tramways for short-distance distribution, the connection of all main line terminal stations with urban tramways and railways, the widening of existing and provision of new streets for local urban traffic and the regulation of street traffic to prevent or reduce congestion, and the provision of complete facilities for passenger interchange. Under the headings, therefore, of "Streets," "Tramways," "Railways," and "Traffic Regulation" the Commission's principal recommendations are grouped.

Recommendations as to Street Improvements.—The narrowness and tortuousness of the London streets are "not a surprising fact when it is remembered how London grew without method or control." The Commission enumerate the various proposals made to them in regard to street improvements, which they remitted to the Advisory Board of Engineers for critical technical examination, and they set forth the proposals of the Board and their own opinion in relation thereto. The projects put forward by the Advisory Board are based upon the view that, as in the case of Paris from 1793, the future improvements of London should proceed on the lines of a carefully-thought-out plan, designed to meet the requirements of through and other traffic, and given effect to, subject to future modifications, in the light of experience, or owing to change of conditions, as time and money permit. With this conclusion the Commission are in emphatic agreement. Although the Advisory Board have not formulated any such complete plan, they advise, as the groundwork thereof, the execution, amongst others, of certain improvements mentioned in the report. The most important is a proposal for the construction of two main avenues through London, one 4¾ miles from west to east to connect Bayswater-road with Whitechapel, the other 4½ miles north to south to connect Holloway with the Elephant and Castle. Each avenue would be 140ft. in width, from house to house, with subways for water-mains; with four lines of tramway on the surface, and four lines of railway below the surface, for express and local stopping trains. The tramways on the main avenues are intended to connect with the tramway systems at both ends, and afford interchange of traffic with the various systems of tramways crossed on the route. The four lines of electrical railway in the sub-structure would be connected with the various railway systems. The Advisory Board of Engineers, it is stated, attach more importance to the west and east main avenue than to the one running north and south, mainly because statistics show the volume of traffic to the east and west is greater. The Commission entertain no doubt that both the main avenues would be of great value in relieving street congestion, and in providing much-needed facilities for central urban tramway and railway locomotion. At the same time they dwell upon the very heavy outlay involved; and on the fact that they are schemes each of which is complete in itself, and cannot be carried out piecemeal. The east and west avenue, with its subways, railways, and tramways, is estimated approximately to cost about £15,550,000, and the north and south avenue about £8,550,000 net. And supposing that a sum of 30 millions sterling would accomplish the work, it would probably require £1,100,000 to £1,200,000 a year to cover interest and sinking fund of the borrowed money. In return for the outlay, the municipality would own nine route and 36 track miles of tramway, and nine route and 36 track miles of underground railway, putting aside the immense advantages of two great thoroughfares. The tramways and railways would bring in a considerable profit. The Commission allude to New York, where an underground railway, with similar accommodation for express and local trains has been constructed at the expense of the municipality by a company under a contract for construction and for operation at an annual rent sufficient to defray interest and sinking fund on the municipal bonds issued for construction of the work. It must be understood, the Commission state, that the Advisory Board of Engineers do not themselves put forward their scheme of new avenues as a project for immediate accomplishment under existing conditions. They desire that its great utility should be realised, and that it should find a place in a general plan for the future development of London as means and opportunity offer. The Commission recognise its utility to the full, and agree that it should find a place in the general plan, if further careful study of the project, from all points of view, shows that it is financially practicable; but do not think that works of less magnitude, which may be within available resources, should be retarded in the expectation of its early accomplishment. The Commission, after consultation with the Advisory Board, recommend that new streets or widened streets should forthwith be laid out according to the following standard of width from house to house, depending upon their importance and the degree to which they are likely to attract traffic: main avenues, 140ft.; first-class arterial streets, 100ft.; second-class streets, 80ft.; third-class streets, 60ft.; fourth-class streets, 40ft. or 50ft.

Recommendations as to Tramways. — The Commission preface their statement of recommendations in regard to tramways by the enumeration of a number of fundamental propositions applicable to urban tramway operations in general, and to London conditions in particular, as follows: Wherever tramways can be laid on existing streets in London without widening, they can, when worked *commercially*, be made a direct source of profit. London in comparison with American and Continental and provincial English cities is conspicuously deficient in tramway

Digitized by Google

facilities; there are extensive districts in the "West-end" and centre of London entirely unprovided for. There is, even where tramways exist, an entire absence of through communication between the various systems within, and between those within and those without the county of London, and every through passenger is obliged to change cars at the junctions, if any, of the various systems. "Accordingly, all the cars are obliged to discharge their passengers at dead-end terminals. At the six principal terminals (Westminster Bridge, Shepherd's Bush, Blackfriars Bridge, Aldgate, Moorgate, and Euston-road) nearly a quarter of a million of passengers alight from or join the cars every day in the streets. Apart from the great inconvenience caused to all or most of the passengers, the result is a very great congestion, both of tramcars and of ordinary vehicular and pedestrian traffic, at these terminal points, and the same congestion, though in a less degree, occurs at the other terminals in London. The Advisory Board of Engineers estimate that the carrying power of a tramway system may be diminished by about one-half by reason of the cross-shunting necessary at dead-end terminals. It will be seen that, from every point of view, tramway accommodation is glaringly defective. In a great area there is no tramway service at all. Where there is such a service, travellers do not obtain the full advantage which it ought to provide in cheapness, expedition, and convenience. An 'end-on' break in the course of a journey probably causes additional expense (for two independent fares usually cost more than a through fare), whilst the consequent delay and discomfort, especially in bad weather, and the uncertainty of transhipment are great drawbacks. Where the line abruptly terminates in the middle of crowded streets, even greater discomfort is caused, together with serious diminution of efficiency in the entire tramway service and an intolerable congestion in the streets. It is difficult to appreciate how such a state of things can have been tolerated so long. Whatever view may be held upon the expediency of extending tramways in London, it cannot be expedient to work those we have upon inefficient methods."

Functions of Street Tramways.—In smaller cities, tramways, the Commission state, supply a double want. They carry passengers from one part of the city to another, and also between the city and adjoining areas, to a distance of eight or ten miles. In London, it is probable that their usefulness will be more restricted. They will be chiefly used for short distances in urban and suburban districts. Experience shows that the metropolitan railways, even where no tramways compete, practically do not attract passengers for journeys of less than a mile. Railways and tramways can with advantage, it is stated, be worked in inter-connection. "Tubes" might be prolonged till they reach the surface at some point in the more open country, and then be continued on the surface as railways or tramways to or beyond the suburbs. Tramways on the streets in urban and suburban districts should, where possible, be laid out in interchange connection with main-line, "tube," and other railways by arrangement with the railway companies. The competitor of the tramway for short-distance traffic is the omnibus, and the horse omnibus, it is said, will always serve a useful purpose in London, unless superseded by the motor omnibus, in distributing passengers where tramways do not penetrate, but the Commission believe that on all the routes, where there is fair competition, the same thing will happen in London as happened in Liverpool between the years 1897 and 1903. Within a period of seven years all the omnibuses disappeared from the streets and gave place to electric tramcars, while the number of passengers carried was nearly trebled. These results, which have been repeated in other cities both at home and abroad, show, it is claimed, how eagerly the public avails itself of tramway facilities. Motor omnibuses will doubtless supersede horse omnibuses, and remove from the streets, greatly to the public advantage, a form of vehicle which, although it has been of great public utility, is now one of the principal causes of congestion in many streets. But the Commission think that, on routes suitable for tramways, where there is a large traffic, tramways will continue to be the most efficient and the cheapest means of street conveyance, and cannot recommend the postponement of tramway extension in London on the ground of any visible prospect of the supersession of tramways by motor omnibuses.

Widths of Streets for Tramways.—Is widening needed to admit of the construction of tramways? "That, indeed," the Commission state, "is the point upon which everything turns. Few would object to an extensive tramway system being laid down all over London but for the belief that it must involve an extensive system of street widening. This is the great difficulty. The opinion is widely held that the streets of London are too narrow for tramways on a great scale. No doubt many streets are too narrow. The real question is whether this disadvantage is so widespread as to necessitate the postponement of a great tramway extension until costly operations of widening have been carried through." In this connection the Commission state that the London County Council aim at a minimum width of 33ft. between the kerbs, but that the Commission think that a greater width than 33ft. is desirable as a rule for a double line of tramway, save that for short distances, or in less frequented thoroughfares, even a less width may be accepted. A single line might be laid in still narrower streets either for traffic in both directions, with passing places at intervals. or for traffic in one direction only. Such an arrangement is common abroad, and appears to work satisfactorily. "Judged by the above standards of width, the report proceeds, many of the main thoroughfares of London will admit of tramways. Of course, the decision must depend partly upon the extent to which the street is crowded, as well as upon its width. Certainly some street improvement is necessary in places from any point of view, and we have already recommended that preference should be given, as far as possible, to improvements which would widen roads intended for tramways, but we are persuaded that a great deal can be done in the way of tramway extension without any great expense of this kind."

Tramway Extensions.—No good purpose, the Commission state, could be served by their attempting to lay down a hard-and-fast scheme for the construction of tramways. The selection of proper routes would require minute examination. They describe and criticise the important proposals reported upon by the Advisory Board of Engineers, who, at their request, have indicated the various directions in London in which the construction and operation of tramways, after making the necessary street improvements, would be beneficial and useful. The routes in question are: across Hammersmith Bridge; Hammersmith to Knightsbridge; Knightsbridge to Aldgate in subway; Fulham and Brompton roads; Grosvenor-place and Hyde Park in subway; Edgware-road and Maida Vale; Harrow-road; Cambridge-avenue; Uxbridge and Bayswater roads; Westminster Bridge and Victoria-embankment; Waterloo Bridge and Blackfriars Bridge; Queen Victoria-street and Southwark Bridge; New Bridge-street and Farringdon-street; Holborn and Charterhouse-street; York-road, Stamford-street, and Southwark-street; Tower Subway; Tottenham Court-road and Whitehall; Moorgate, Liverpool-street, and Norton Folgate; Aldersgate-street to Post Office in subway; King's-road, Chelsea, and Buckingham Palace-road; Victoria-street, Westminster; Marylebone and Euston roads; Finchley-road. The advantages, the Commission state, of some of these proposals are obvious. If they were carried out, a tramway along the Euston and Marylebone roads and the Edgware-road would connect the existing eastern and western systems, passing quite close to five of the principal railway termini in London; north and south would be connected by two lines outside the City; four lines from the west would penetrate to the central area and thence be continued to the eastern districts; not least in importance, tramways would cross the Thames on two existing bridges (Westminster and Blackfriars), which would be united by a line along the Thames Embankment. Thus urgently needed through communication would be afforded. In short, the three isolated systems which we have described would be linked together, the central area, hitherto destitute of tramways, would be partially opened out, and the Thames would no longer interrupt communication between north and south. Some

Digitized by Google

of these proposals of the Advisory Board of Engineers are undoubtedly open to criticism. They involve, in all, about seven miles (excluding the subways under the proposed main avenues) of tunnels or subways. There are parts of London, the Commission say, where the value of land is so great, notably in the City, that widening for tramway purposes is not to be thought of. In such places the only course is to construct subways. But that is not so everywhere, and, for the most part, if the choice lies between subways and widening, the Commission believe that it will be found nearly as cheap to widen the streets and lay tramways on the surface. In any case it must be a question of relative cost, with the additional consideration that travelling on the surface is always preferable and a wide street always an advantage. The Commission do not think that a case is made out in favour of a subway being constructed from Albert Gate along Piccadilly to the City, or for the tunnel beneath the Thames east of the Tower Bridge to unite existing terminals in Leman-street and Tower Bridge-road. As to the proposals within the city of London, some involve subways, others are for surface tramways. The Commission think that surface tramways should be laid down in the City where they can be shown to be reasonably practicable, and that subways should be made where surface tramways are not practicable. The Commission think the Grosvenor-place and Hyde Park subway, which would relieve the congestion at the crossings at Hyde Park-corner and Marble Arch, is so important that it should be taken in hand with as little delay as is possible. On the Euston and Marylebone roads, Bayswater-road, Hammersmith-road, Fulham-road, and King's-road, Chelsea, as well as on the other roads on which tramways are proposed, some street improvements will, at places, be required, and extensive improvements, in the way of widening streets, would be an advantage upon all the routes. In King's-road, particularly, considerable street improvements will be necessary; but if the construction of tramways were delayed until the full width recommended of 100, or even 80, feet could be everywhere secured, the introduction of tramways might be postponed indefinitely, owing to the great cost which such improvements would involve. The Commission believe that most of these routes could be laid out for tramways with only a moderate outlay for widening in particular places, and are so convinced of the urgent necessity for tramway accommodation in London, that they recommend that the work on the five routes in question should be taken in hand as soon as possible. The Commission think it unnecessary to indicate other routes with regard to which the same course might be followed. The illustrations already dealt with they think sufficient. If these works are executed, and the travelling public realise the advantages anticipated, further extensions, they say, will follow as a matter of course.

Tramway Operation.—Through communication—that is, the running of through cars over tramway systems, separately owned, without rebooking or transhipment of passengers—is of great importance in the interests of cheap, expeditious, and convenient locomotion, and the refusal of reasonable facilities for that purpose should not be allowed, but should be enforced, if necessary, by the grant of running powers. Where, however, through running of cars is impracticable, through bookings and an interchange of passengers, at convenient times and places, should be secured. Tramway systems within "Greater London" ought to be worked by one and the same authority, and that for this and other reasons. The Commission do not deal directly with the question of the municipal operation of tramways, as being outside the terms of their reference. They state, however, that they think it reasonable that some profit should be derived from the tramways for the benefit of the municipality, but that it does not follow that the best way of securing the largest profit will be that the municipality, even if it finds the money for construction, should undertake the task of operating. In other countries it is not unusual for municipalities to construct, purchase, or otherwise acquire the tramways, but in such cases the actual working is generally left to operating companies, with provision for proper rates and general control. It is claimed that such methods yield better financial results to the municipalities, and avoid difficulties which might arise from municipal authorities carrying on a business of this kind on a large scale. Abroad, the work of construction is also often facilitated by the same company that is afterwards to operate also undertaking the construction by contract with the municipal authorities, who are thereby saved from the risks and disadvantages attendant upon the making, as well as the working, of a line by a municipality. If the tramways are operated by the municipalities concerned, the Commission say they should be worked on sound financial principles, with ample provision for depreciation and repayment of capital or discharge of debt, and that any profit from tramways received by a municipality should, preferentially, be applied to necessary tramway developments, and to street improvements, and to meet expenditure which otherwise would fall on the rates.

Tramway Legislation.—The Commission strongly recommend the consolidation of tramway and light railway law. The Commission recommend the abolition of the "veto" of local and street authorities and of frontagers, and to provide that in "Greater London" the county councils and the Corporation of the city of London shall have a preferential right to construct any tramways within their districts if they are prepared to do so. Instead of a "veto," they recommend that local and road authorities should have a *locus standi* to appear before the Traffic Board and Parliament in opposition to any tramway scheme within their district, by whomsoever such tramway scheme might be promoted. In the same way, frontagers, who have at present a veto under the Tramways Act, 1870, should have a *locus standi* upon any tramway scheme affecting their property.

The recommendations of the Commission as to railways and the joint operation of railways and tramways in large systems we propose to leave to another issue, and also the proposed duties of the suggested Traffic Board. This, it is advised, should consist of three or five members, who should be capable men of business, energetic, impartial, and able to devote, if necessary, their whole time to the work of the Board.

THE GALBRAITH ELECTRIC FURNACE.

On Wednesday last the furnace above mentioned was shown in operation in an experimental form at the Brush Company's works at Loughborough. The furnace has been designed to deal specially with the iron sands which are found in very large quantities at Calliope Dock, Auckland, New Zealand, and elsewhere in that colony. We understand that all previous attempts to treat this sand have failed, in spite of the fact that it consists almost entirely of magnetite. The difficulty has been to reduce and smelt the sand, which chokes up all the types of blast furnaces which have been experimented with. Attempts which have been made to treat the sand after forming it into briquettes have also failed. The Galbraith furnace enables this sand to be treated continuously, and the inventor's figures give hope that the cost of treatment where cheap water power is available will be sufficiently low to make the process a commercial success. The furnace which we illustrate in Figs. 1, 2, and 3 is the earliest form which was experimented with in New Zealand. The drawings are incomplete, and show only the active portion of the furnace where the reduction of the iron sand and subsequent smelting was effected. It will be seen that a number of rods, marked A A in the drawings, pass through from one side of the furnace to the other. These are made of graphite, and are maintained in an incandescent state by the passage of electricity through them. The side linings of the furnace, marked B B, can also be of graphite when parallel connections are used for heating the incandescent bars. The end lining, C C, is made of a refractory material which is also an insulator. The iron sand is then fed into the top of the furnace, and it trickles down over the incandescent bars, being first reduced and afterwards melted. In the furnace which we saw working at Loughborough on Wednesday the form of the incandescent bars was very

Digitized by Google

different to that shown in the drawing. Each line of bars was moulded out of graphite in the form of a grid, the section of each bar being diamond-shaped, with its long axis horizontal. The space between two adjacent bars was small compared to the width of the same, and the alternate grids were staggered, so that these openings in one set came immediately over the centres of the bars in the next set. In the Loughborough furnace the voltage applied to the bars was about 18 volts alternating, which was obtained from a 100-kw. oil-cooled transformer. The iron sand can either be reduced in the furnace itself—in which case a certain amount of powdered carbon has to be introduced with it—or it can be reduced beforehand by a preliminary roasting, as was the case in the experiment we witnessed. The sand is then fed into the top of the furnace, and is gradually melted as it passes down over the incandescent carbon bars. It falls into a receptacle at the bottom, which in practical work would be heated, and from which the steel obtained could be drawn out for further treatment, so as to obtain a uniform product. As collected in an uncooled receptacle the product has subsequently to be melted again, and there were on view a number of small ingots which had been prepared in this way. It will be seen, therefore, that the furnace is simply used to reduce the iron sand into metallic iron or steel, and that the removal of any impurities in the sand or the decarbonisation of the steel has to be carried out as a subsequent operation, which can be, however, effected

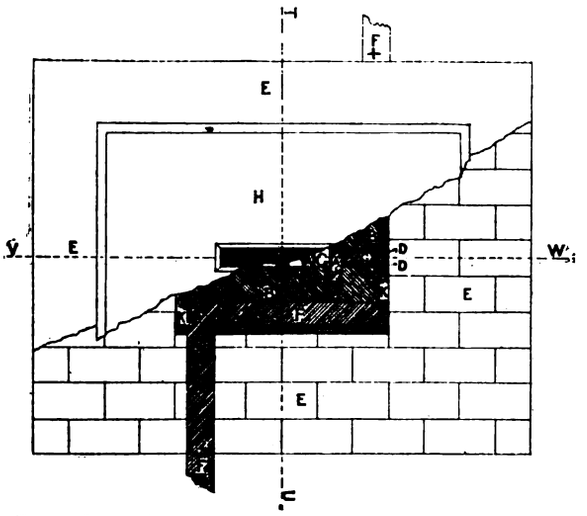

FIG. 1.—Plan of Galbraith Experimental Furnace for Treatment of Iron Sand.

without a complete remelting of the product from the electric furnace. The electrical details for conveying current to the graphite bars have yet to be perfected, and the cost of upkeep will depend on such details and on the life of the blocks in question. The inside of the furnace is always filled with carbon dioxide, so that the wasting away of the bars should not be rapid. The bottom of the furnace into which the molten metal drops is kept closed and sealed, so that no air passes into it. The upper end of the furnace as shown at Loughborough was closed by the box through which the reduced iron sand was fed in. The result was that there was a slightly higher pressure inside the furnace than out, which caused lighted gases to issue from the joints between the graphite blocks and the furnace walls. We were also shown a number of these blocks which had been used for a considerable run, and which showed no signs of being reduced. There was no attempt in the experimental furnace to keep in the heat, and consequently the radiation losses were large and the temperature round the furnace unpleasant. It is obvious, however, that this radiation can be cut down to a very large extent by some such construction as is shown in the illustrations herewith. Any figures as to output and cost which have been obtained at present are bound to be high, owing to the experimental nature of the trials. Mr. W. Steuart, who as an electrical engineer has taken up the development of the furnace with the inventor, succeeded in reducing steel at the rate of 38lb. per hour with the furnace illustrated. In this experiment the sand was both reduced and melted in the furnace, and the consumption of energy was 1·1 units for this amount. In considering this furnace it must be borne in mind that it is designed for a special object and for the treatment of material which, though exceedingly

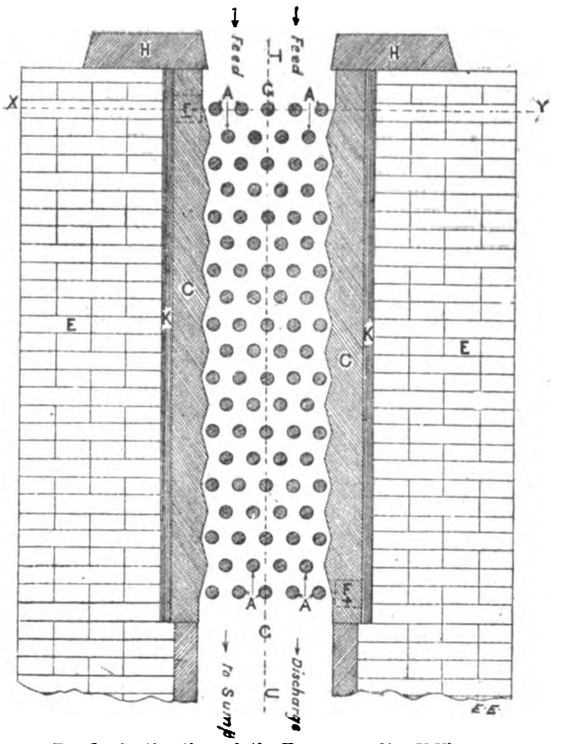

FIG. 2.—Section through the Furnace on Line V W.

rich in iron, has hitherto defied all efforts of the metallurgist. From this material the Galbraith furnace has produced steel with a consumption of energy for a given weight which would be warranted if cheap power is available. It seems that in New Zealand there are two large waterfalls—*i.e.*,

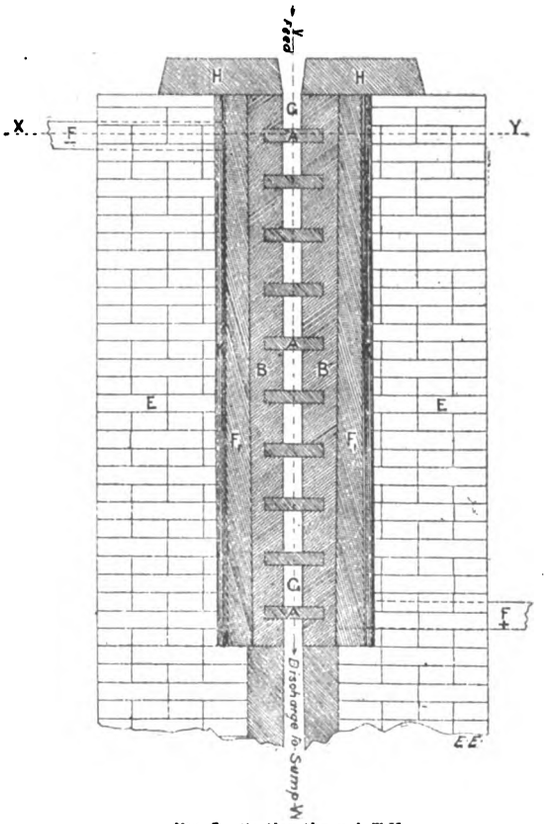

FIG. 3.—Section through T U.

those at Huka and Ainwhaniwha—from which energy could easily be transmitted to these iron sand deposits. At each of these falls 10,000 h.p. could be obtained at a very small cost per horse-power per annum. Mr. Steuart's estimate of this cost is in the neighbourhood of

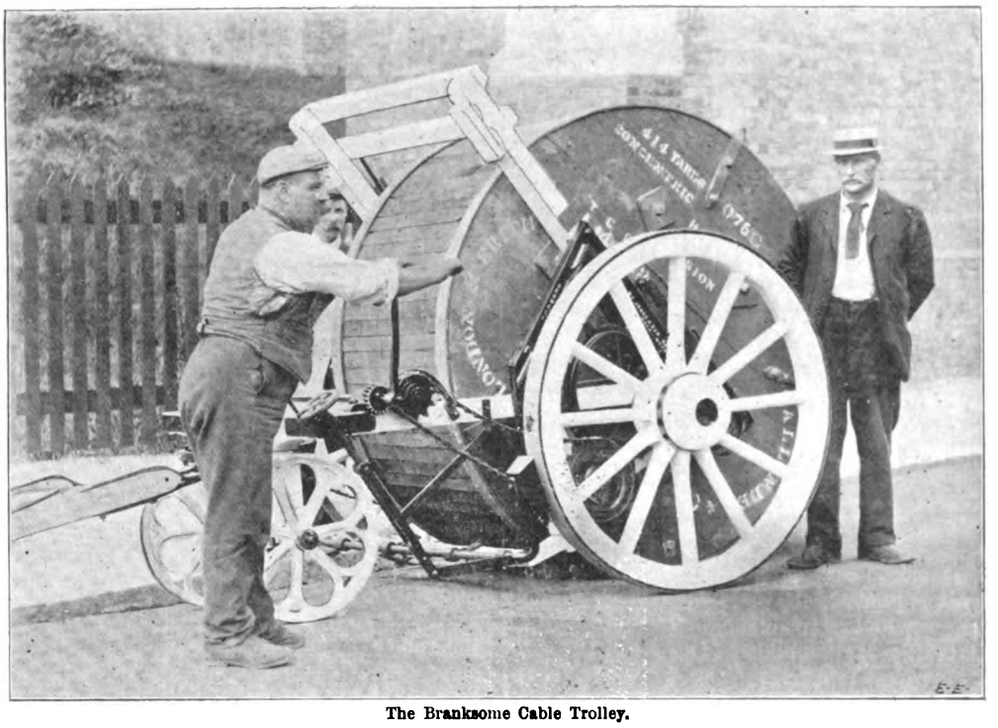
Digitized by Google

30s. per horse-power per annum. Such a low figure brings the cost of electrically heating a furnace down to a point at which it can compete with a furnace using fuel. In this respect it must be remembered that in the electric furnace acting on the reduced sand, only the heat required to melt the iron has to be provided. In the fuel-fed furnace, the materials which pass through include fuel, slag, and the necessary air for combustion purposes. It is known, for instance, that the actual weight of the gases leaving a blast furnace is about seven times more than the iron produced. The heating up of material other than iron, therefore, is responsible for quite a large proportion of the fuel required. The Galbraith furnace has special advantages for the special work contemplated, and we trust that by its aid the iron sand deposits, not only in New Zealand, but also in Canada and elsewhere, will be added to our other sources of commercial iron and steel. The Galbraith Iron and Steel Company, Limited, are developing this furnace, and has at present London offices at Cannon-street Hotel, E.C.

ELECTRIC TRAMWAY AND RAILWAY EXHIBITION.

(Continued from page 53.)

THE BRANKSOME CARRIAGE AND MOTOR WORKS, of Poole-road, Bournemouth West, showed a cable-drum trolley which is worthy of note. The details of this trolley can be seen in the accompanying illustration. It has for its object the reduction of labour in the handling of cables for underground mains, and is so constructed that one man can load up drums of cable weighing as much as five tons. It will be seen from the photograph that the upper part of the trolley is hinged. To load up a drum of cable, this is first tilted up. The carriage is then backed over the drum, and the usual axle bar is secured to the upper side of this hinged portion. By means of a pinion driven by the handle shown and gearing into a tooth rack the upper part of carriage is then moved back, which raises the drum off the ground. The details of this cable trolley are substantial throughout. We understand that it has done good service at Bournemouth for the Bournemouth and Poole Electricity Supply Company.



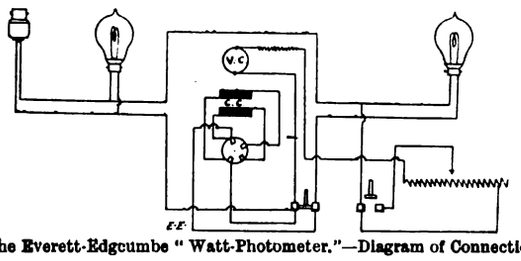
The Branksome Cable Trolley.

THE ST. HELENS CABLE COMPANY, LIMITED, were showing a representative selection of their numerous manufactures and raw materials used. Perhaps the principal attraction was a solid piece of Para rubber. This is the largest single piece ever imported, the weight being 1,100lb., and its value, roughly, at the present market rate, £300. Another interesting item was a machine designed to show that the company's dialite cable is not subject to trouble from low temperatures, such as the cracking of the dielectric when bent. To demonstrate the advantages of dialite in cases of low temperature, they showed a piece of dialite cable being continually bent backwards and forwards by this machine, at a temperature of 30deg. F., the cable being under an electrical pressure of 2,500 volts during the whole of the time. That this cable gives equally satisfactory results under conditions of extreme heat, has been demonstrated on former occasions. The exhibit included many samples of different forms of cable made by the company and coils of copper wire drawn by them; also a pyramid of drums loaded with trolley wire, of which they manufacture a very large amount, electrical lift rope, and steel span wire. The remainder of the exhibit consisted of fireproof cables, rubber cables, indiarubber gloves tested to 5,000 volts, insulating and waterproof tapes, mats, matting, motor 'bus tyres, packings, insertions, tubing, and various other mechanical rubber goods. We noticed particularly some rubber-lined leather gloves, the leather giving effective mechanical protection to the insulating material. Reference may also be made to the high quality of the insulating mats shown. The whole made an exhibit well calculated to enhance the reputation of the company for reliability of goods supplied.

MESSRS. EVERETT, EDGCUMBE, AND CO., LIMITED, had a good display of instruments on their stand. These included a direct-reading "watt-photometer." This instrument is so arranged (see the accompanying diagram) that a single adjustment enables the following quantities to be read off direct: (1) candle-power; (2) watt consumption; (3) efficiency in watts per candle-power. The apparatus consists of a polished mahogany case, which when open forms a direct-reading photometer having a Trotter pattern head. The arrangement is such that any variation in the voltage either up or down from the normal does not in the least affect the accuracy of the candle-power measurements. A wattmeter is also fitted in the case, and on pressing a key the pointer indicates the watt consumption of the lamp. A further key is provided, on pressing which the instrument indicates the watts per candle-power direct. This is accomplished by causing the photometer carriage, as it is moved backwards and forwards according to the candle-power of the lamp, to vary the resistance in series with the volt coil of the wattmeter in such a way that the instrument reads "watts/candle-power" instead of "watts." By means of this instrument the candle-power and efficiency of a whole batch of lamps can be determined in a few minutes, and this in broad daylight and without any precautions being taken as regards the adjustment of the voltage. All measurements are made direct, no calculation

Digitized by Google

whatever being necessary. Reference may also be made to the company's leakage indicators for direct and three-phase currents designed to comply with the new regulations for the use of electricity in coal mines. Rule 6 of the regulations in question states that the leakage current—that is to say, the current passing from one main to the other through the earth—shall not exceed one-thousandth part of the maximum supply current; and Rule 7 states that in every completely insulated system leakage indicators are to be connected up to show immediately the occurrence of any fault, and that daily readings on these instruments are to be entered up in a book kept for the purpose. In the case of the direct-current instrument, when the switch is in the normal position a deflection to the right or to the left indicates a fault on the positive or negative main, as the case may be. The other two points on the switch connect the instrument through a resistance between each main and the earth. It has been sometimes stated that the readings on these two stops give the actual leakage current as demanded by the Home Office. This is, of course, not so. A table, however, accompanies the instrument, from which not only the actual leakage current, but also the insulation of the positive and negative mains, can be at once read off. It may, perhaps, be stated that these results do not depend for their accuracy on the assumption that the insulation of the main to which the instrument is connected is perfect, but are equally accurate however faulty either or both mains may be. In the case of three-phase systems three resistances are joined to form an artificial neutral point, and a sensitive milliampere-meter is connected between this and the earth.



The Everett-Edgcumbe "Watt-Photometer."—Diagram of Connections.

Normally, no deflection will be obtained. If, however, the insulation of any one of the mains should be faulty, the deflection will be at once observed. Further readings can be taken by connecting the instrument between each of the three mains and the earth, from which a very good idea of the state of the system is obtainable.

The Everett-Edgcumbe Inkler synchroniser recorder is another instrument well worthy of notice. The chief trouble met with in the design of a satisfactory recorder is, firstly, to overcome the friction between the pen and the paper; secondly, to cause the instrument to read correctly whether the pen is full of ink or nearly empty; to prevent spilling of the ink and consequent blotting of the records, and to provide a satisfactory arrangement for working forward the paper chart. In the recorder under review the pen is replaced by a hardened steel point, which does not press on the paper, and thus is quite free to take up its correct position. At equal intervals of time—usually every five seconds—a tapping device causes the steel point mentioned above to press through an inked typewriter ribbon on to the paper chart. The result is that a round dot is produced on the latter, the position of which corresponds accurately to the voltage or current, or to whatever is being measured. The intermittent tapping is produced by means of an electrical clock, which closes a circuit every five seconds, and thus actuates an electromagnet in the recorder itself. A second electromagnet in the recorder at the same time drives the paper chart forward through a definite amount. It may, at first sight, be thought that an electric contact introduces a complication into the system, but it has been found, after many years' experience, that such electric clocks work without any attention whatever for years at a time, and are, moreover, more accurate timekeepers than the ordinary clock. A single timing mechanism can be employed to actuate a number of recorders, either a battery being employed as a source of current, or, where available, the supply mains. Also, in series with these recorders, can be connected any number of clock dials, which not only serve as clocks, but also show at once that the paper charts of all the recorders are timing correctly. The construction, as above described, is such that a much smaller electrical instrument can be used for measuring purposes. For direct current, a moving-coil instrument is employed, while for alternating currents either the dynamometer type as in the case of recording wattmeters or recording power-factor indicators, or the moving-iron type for ammeters and voltmeters. For high-tension circuits, the instruments are worked through series or current transformers. The paper chart is usually supplied in the form of long rolls, lasting a month at 1in. per hour (which speed can, of course, be varied as required) and, as the paper is passed through the instrument, it is automatically wound up on a drum until required. The electric clocks used in connection with these instruments are constructed on the "Hope-Jones Synchronome" principle and are absolutely self-winding, so that no attention is required by the recorder, except to change the charts once a month. The currents working the system only flow for such very short periods that the energy absorbed is negligibly small, amounting, perhaps, to some 10 ampere-hours per annum per recorder, at a voltage of four or six volts. The indicating ribbons are in the form of continuous bands, and only require changing at rare intervals. For alternating-current instruments a special astatic moving-iron system is employed, which consists of two "Universal" ammeter coils wound in opposite directions, and each acting on a separate soft-iron disc. By this means any stray field which may exist in the neighbourhood of the instrument strengthens one coil by the same amount that it weakens the other, so that the effect on the reading is nil. In the case of switchboard instruments the whole is enclosed in a cast-iron case, which forms a further protection, so that the recorders are absolutely unaffected by stray fields, whether the movement be of the moving-iron or the moving-coil type. The controlling clocks are of two forms, and work either with a pendulum or balance-wheel escapement, according to the use to which they are to be put. From what has been said it will be seen that practically the same accuracy is attainable with these recorders as with an ordinary central-station instrument.

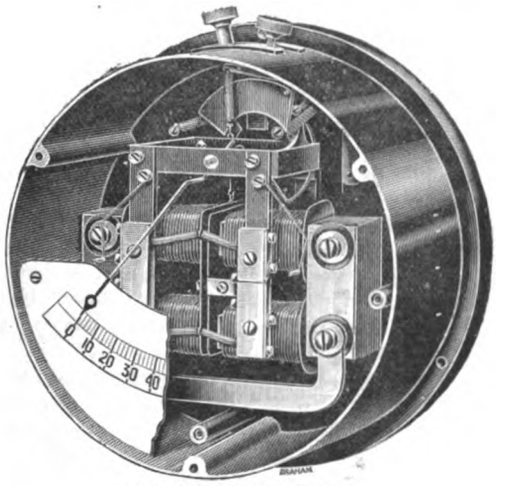
A notice of this interesting exhibit would be incomplete without mention of a portable street photometer which has been designed as the result of numerous experiments, and embodies the following important points: (1) a portable electric standard is employed, which can be readily checked at any time, and which is worked off a portable accumulator; (2) lights of various colours can be readily compared, the photometer being constructed on the "flicker" principle; (3) the scale reading has merely to be multiplied by the candle-power of the lamp employed in order to give the actual illumination on the photometer; (4) the candle-power of the source of light under test is at once obtainable by means of a table from this figure, as is also the illumination on a horizontal plane should this be required. The flicker arrangement is a modification of that employed in the "Everett-Edgcumbe laboratory photometer" for arc lamp testing, and it is especially designed to get over the errors usually found when comparing incandescent electric lamps with arc lamps or incandescent gas. The instrument is as portable as it can be made, and no previous experience whatever is required in order to use it.

On their stand MESSRS. NALDER BROS. AND THOMPSON had a large assortment of electrical measuring instruments for all purposes, both direct reading and recording, several typical switchboard panels being shown with instruments, switchboard, and circuit breakers complete. There was a new type of circuit breaker, consisting of the overload and reverse current variety, fitted with carbon brakes and magnetic blow-out. This instrument has the spread-brush form of contact, and possesses the advantage that if the short circuit remains on it is impossible to replace the switch. The switch is fitted with a free handle, and represents the most up-to-date and complete form of circuit breaker. We noticed some moving-coil switchboard instruments in new sizes, such as the very small edgewise type, as also a very large station voltmeter of the illuminated dial type; also a new type of soft-iron instrument in an iron case, known as

Digitized by Google

the O.K. type. This instrument is either for direct or alternating currents, and is screened so as to render it unaffected by external fields, and fitted with an improved form of air damping.

A new form of wattmeter was also exhibited. This instrument was invented and patented by Dr. C. V. Drysdale, D.Sc., and presents many points of novelty. The accompanying illustration shows its working parts with the cover removed. The instrument consists essentially of four fixed current coils, wound on soft-iron cores; these cores are arranged to give a very intense field with a very small air-gap. Between the poles of the magnets are two flat coils wound with fine wire, which constitute the pressure coils.



The Drysdale Wattmeter.

These are wound in opposite directions, and as each is arranged to have an equal number of turns, the self-induction of the pressure circuit is practically nil, consequently the correction which would have to be applied due to this factor is eliminated. Of these two pressure coils, the thickness of which is only $\frac{1}{60}$in., one is fixed and the other allowed to move vertically in the field produced by the current coils. This vertical motion is transformed into a rotary one by means of a fine wire attached to the coil, which passes over an arbor to which the pointer is attached. To the pointer axis is attached an improved form of air damping, which makes the instrument dead beat. The advantages of this instrument are many. Firstly, owing to the extremely little space taken by the pressure coils the magnet air-gap is very short in length, consequently a very strong field is produced, which gives large force in the instrument, and at the same time renders the instrument unaffected by external fields. Secondly, the coefficient of the self-induction of the pressure circuit being negligible, the errors at low factors are very small—in fact, careful testing on this form of instrument shows that it can be guaranteed to within 1 per cent. with power factors as low as one-tenth. These results, we believe, are the best that have been attained so far in alternating-current wattmeters. The instrument is mounted in an iron case, and is provided with two adjustable screws, one for clamping the moving coil when the instrument is in transit and the other for setting the zero. A large number of these instruments have, we understand, been supplied to various power stations in the kingdom for use in connection with transformers.

THE LANCASHIRE DYNAMO AND MOTOR COMPANY, LIMITED, Trafford Park, Manchester, were exhibiting, among other machines, one of their automatic reversible booster sets (Turnbull and McLeod patents). This, indeed, was the principal feature of their display, and although similar sets have already been supplied to several central stations, it merits more than passing notice here. These boosters, it may be explained, are chiefly used for working on traction systems with a battery in parallel with the generators, the object being to keep the load on the dynamos practically constant, the battery discharging at times of heavy load and charging at times of light load. They are also of use in works where the motors are large and started and stopped frequently, or in any other place where the load is of a varying character. Taking into account the large variations in the voltage of a battery (not only with varying current, but with the same current at different times), it is evident that the first requisite is an exciting coil which shall always make the sum of the battery and booster voltages practically equal at all times to the 'bus-bar voltage. This is accomplished by putting on a coil, A (see the accompanying diagram), excited by the difference between the battery and 'bus-bar voltage. If the booster is worked on the straight part of the characteristic, it will be seen that the coil can be made to give a voltage on the booster armature always equal to the difference between the battery and dynamo voltage, so that, no matter what the state of the battery, the booster always brings the battery up or down to the 'bus-bar voltage. If, now, another coil is added a very small current in this will cause a very large difference in the booster voltage. For instance, a shunt coil, B, across the 'bus bars would increase the voltage on the booster, which would again increase the strength of coil A, and the battery would heavily charge. If, on the other hand, instead of B a coil is put on wound in the opposite way, the voltage of the booster would be altered so as to produce a heavy discharge. The last coil is a series coil, C, arranged to carry the whole or part of the dynamo current, and is arranged so as to oppose coil B; then, any increase in the ampere-turns of B above C will cause the booster to build up so as to heavily charge, and any decrease of B below C will cause the battery to discharge. A few series turns are usually added in the battery or feeder circuit to make up for the armature reaction, and C R drop of the booster itself. To take the case of the booster on a traction system; if the dynamo tries to take an overload the coil, C, would over-

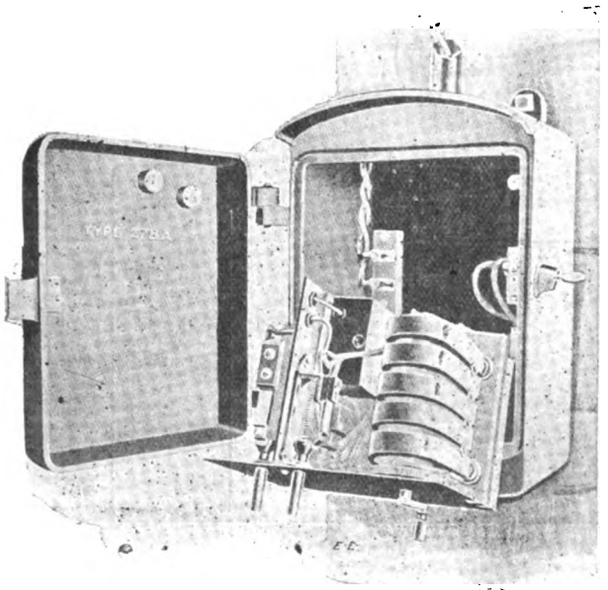
Digitized by Google

power B and the battery discharge until equilibrium was restored; on the other hand, if the dynamo current tries to reduce on light load, B overpowers C and the battery charges until they are balanced. As the booster depends for its control on the dynamo current, and not on any balancing of voltage, depending on the dynamo characteristic, compound machines may be used as well as shunt, and all trouble from hunting and kindred causes is avoided. Most boosters which do not depend on the falling characteristic of a shunt dynamo rely on the drop in volts on the battery and booster in discharging, which is balanced by a series coil in the feeder. If this coil is not exactly of the right strength, the battery discharges too much or too little, usually varying with the state of the battery. The particularly valuable property of a coil in the dynamo circuit consists in the fact that it can be made as strong as desired, and always balanced by a regulator on the shunt coil to fix the dynamo current on anything required; and if the current should vary, acts with very great force to bring it back to the normal again, thus making the booster very stable and greatly facilitating paralleling. If it is desired to use the battery and the booster on the line without the generators, coil A is disconnected and coil C connected to help B giving the battery a constant voltage with varying load.

Of the various apparatus shown by the WESTERN ELECTRIC COMPANY, special reference may be made to



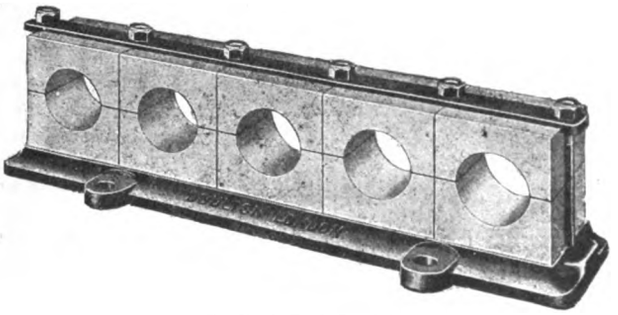
Western Electric Co.'s Traction Telephone Set.

their patent traction telephone set. In connection with street railways and electric tramways the need has arisen for means of communication between drivers or motormen and the generating station and engineers. In cases of breakdowns, accidents, or flooding of the permanent way, it is essential that the facts shall be promptly communicated to the responsible officer, so that he may take the necessary steps for preventing a complete interruption of the service. It has been kept in view in designing the telephone under notice that a traction set must be eminently reliable under all atmospheric conditions; it must be strong and able to withstand a considerable amount of rough usage. The operation of the set must be simple and as nearly automatic as possible, so that even under the greatest excitement there will be no difficulty in establishing communication instantaneously. The parts of the set must be easily accessible for inspection and repair, and, the most essential point of all, the operator at either end of the line must be efficiently protected from danger should the telephone lines become crossed with a high-voltage traction circuit. The whole should, of course, be enclosed in a mechanically strong weather-proof case. The outer case consists of a cast-iron box, with ample flanges to ensure protection from damp weather, and is fitted with a reliable lock. It is in a form suitable for mounting on the side of a feeder pillar or trolley pole. The set is also made up in cases without lugs, suitable for mounting on the top of cast-iron pillars in the same manner as the well-known fire-alarm sets. To communicate with generating station the motorman turns the generator crank a few times, and then by means of the combined transmitter and receiver, of the form commonly known as a microtelephone, converses with the engineer at the station. At the upper part of the set there are two projecting rods; these engage with the anvils cast in the front of the outer door and operate switches which respectively open the transmitter circuit and cut the apparatus entirely clear from the line when the door is closed. This is a very important part of the set, for the automatic opening of the battery circuit prevents waste of the current, and the opening of the line circuit serves the double purpose of preventing damage to the set in the event of a cross of the telephone line with the traction circuit, and permits an unlimited number of these sets to be placed in "bridge" across one pair of lines, which may thus serve for a whole route, or in small systems for the whole network, and thus save the expense of providing switching apparatus at the generating station. The accompanying illustration shows the inner case of the set opened for inspection or repair. It will be seen that all the apparatus is mounted on a sliding base which runs in guides cast in the side of the set, this arrangement enabling the whole to be removed into a convenient position as shown for inspection. The shelf is locked into position by a locking lever having an ear adapted to serve as a handle by which the lever may be rotated and the shelf unlocked so that it may be moved forward. It is prevented from being completely removed or from falling when drawn forward for inspection by lugs which engage with stops in the guides, but can be entirely removed for repair by simply drawing it forward until the lugs are opposite the openings in the guides and then lifting the shelf vertically. This is of considerable advantage, for should the apparatus become deranged so that removal to a distant point is necessary, the linesman simply removes the shelf and replaces it temporarily by a spare one. The sliding out of the shelf serves to automatically disconnect the apparatus from the line with which it is associated. Included in the circuit of the apparatus are line fuses so arranged that if abnormal currents are present on the line the fuses blow while the door is being opened, thus constituting a signal whereby the person desiring to use the instrument is apprised of the abnormal and dangerous condition of the lines. The fuses entirely disconnect the apparatus before the person has time to grasp the handle of the generator or microtelephone. In addition to this, a lightning or high-voltage protector of the open space carbon cut-out type is provided, which serves to effectively earth the line in the event of connection with a circuit of over 300 volts potential difference. This will cause the fuses previously mentioned to be operated and isolate the apparatus. Further protection is obtained by interposing a repeating coil between the telephone apparatus and the line. This repeating coil or transformer is wound with double silk-insulated copper wire, enclosed in an earthed metal case filled with special insulating compound, and allows telephone currents to pass by induction from the set to the lines without there being any metallic connection between them. A very important feature of this set is that the protective apparatus and the telephone apparatus are arranged in separate groups with an earthed metallic shield between them, so that any dangerous high-potential condition that may exist in the compartment wherein the protective devices are mounted may not be communicated to the telephone apparatus, but may instead be diverted through to earthed shield interposed between the two groups. All portions of the set accessible to the person making the communication are earthed upon the feeder pillar or trolley pole. Another feature which will be greatly appreciated by users of this set is that all parts are standard apparatus and readily interchangeable, and can be supplied from stock should it be necessary to change or replace any of them. Included in the exhibit were samples of the company's "Electrose" insulators for overhead line work. The tests to which this material has been subjected show its mechanical strength and insulating qualities to be exceptionally satisfactory. Nor has twelve months' exposure to weather on the Niagara Falls Power Company's

Digitized by Google

high-tension transmission line to Buffalo had an appreciable effect on the surface of the material, we understand. Switchgears, ventilating fans, small motors, cables—the latter including a sample of the Liége telephone cable—and other specialities too numerous to mention in detail completed a representative exhibit of the firm's high-class manufactures.

MESSRS. DOULTON AND CO., Lambeth, exhibited a fine selection of their specialities for electrical work. Prominence was given to conductor rail insulators, more particularly those of the "Pedestal" type, for particulars of which we would refer the reader back to an illustrated notice in our issue for Sept. 9, 1904, p. 383. We noticed samples of platform copings, such as the company have supplied for the District Railway and tube lines of London, also a large variety of fuse bases, fuse handles, fuse-box insulators, etc., besides many standard patterns of insulators in both stoneware and high-grade white porcelain for telegraph, telephone, traction, transmission, and other purposes. Needless to say, ducts for underground cables and Doulton's very useful bridge insulators for "solid system" laying were included. The rack insulator illustrated herewith comprises a base of cast iron supporting a set of cleats. Each cleat consists of a pair of grooved insulators in cream glazed vitrified stoneware. The cleats are made with grooves of different sizes to take cables up to 2¾in. diameter, but they are of uniform external dimensions, and, therefore, interchangeable. The parts are held firmly in position by bolts, the upper ends of which pass through an iron or fibre strip lying in a recess in the cleats. The rack may be built up to take several tiers of cables. Reference may be made in conclusion to some specimens of plumbago



Doulton's Rack Insulator.

crucibles and chemical-resisting ware, which completed the exhibit. The whole served incidentally to show to what a high degree of perfection Messrs. Doulton and Co., Limited, have developed this branch of their business.

ELECTRIC WINDING MACHINES.*

BY PROF. PAUL HABETS, OF BRUSSELS.

The ever-increasing application of electricity to mining machinery, and the economy resulting from centralising the generation of energy required for working large undertakings, has not been kept back for want of finding means for working winding machinery electrically. When it is a question of underground mechanical haulage, the electric transmission offers enormous advantages over all other systems (steam, compressed air) with regard to economy and facility of installation. But the exaggerated fear of introducing electric plant into explosive mines, the cheapness of machines by compressed air and also the possible utilisation of existing compressed-air plants, have retarded the great development of electric haulage in underground workings. Even in the case of the main winding machines, which can be placed close to the steam-engines, electric driving has been introduced during the last years with the object of reducing the consumption of steam. This economy is, however, doubtful. The losses due to the transformation of electric energy may, in fact, equal the unfavourable conditions under which a steam winding engine is working if the latter be an economical condensing engine. The economy is certain, however, when the winding machine must be placed further away from the steam-engine, or when the use of electric transmission permits of doing away with boilers. In designing a steam winding engine it was generally considered sufficient to determine the resultant statical moment of the rope-roll. The use of electric driving has necessitated a study of the dynamic conditions of the problem, which is not without importance also in designing steam winding engines, if it be desired to work the engine under the most economical conditions. The author brought to notice at the exhibition of electric winding engines at Düsseldorf, 1902, the study of the dynamic conditions of haulage for machines with ropes and perfectly balanced, winding machines with cylindrical drums and with counterbalancing ropes, and machines with Koepe's pulley. The latter was at that time the only machine to which direct driving by electric motors had been applied. At present the application has been extended to machines with variable rope-roll, notably to the machine installed at the coal mines of Grand Hornu. It seems, therefore, desirable to investigate the question more closely.

DYNAMIC INVESTIGATION OF HAULAGE.

Statical Moments.—The law governing the relation between the statical moments and the number of revolutions made by the shaft which carries the winding gear of the ropes may be determined by calculation or by a graphical method shown by M. H. Dechamps. As an example, the author has selected the electric winding engine installed at the coal mines of Grand Hornu. The following data have been furnished by M. E. Trousart: depth, 1,000m. (3,300ft.); useful load, six wagons, 2,600 kos. (2½ tons); dead load, six wagons, 1,260 kos. (1¼ tons); dead load, one cage, 2,000 kos. (two tons). The flat aloes rope is taper and of the following dimensions:

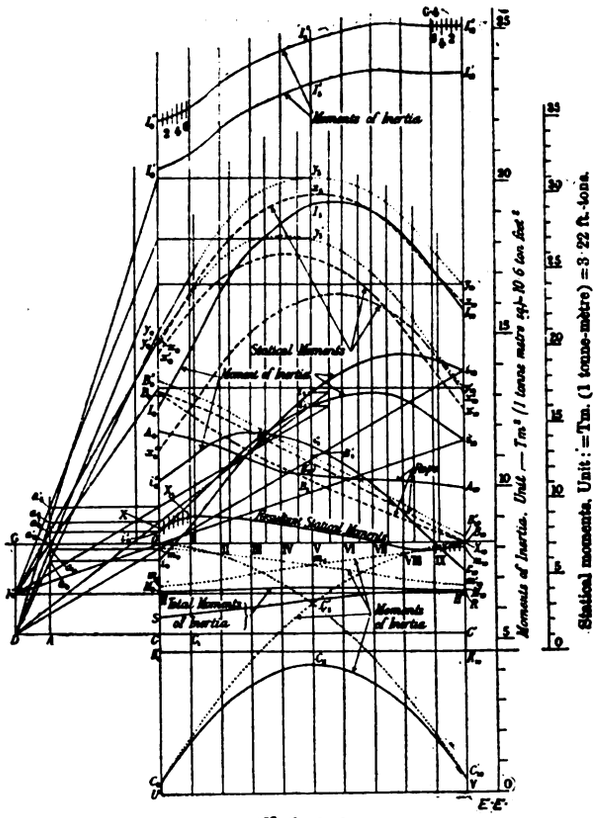
The diameter of the bare drum is 1·40m. (4ft. 7⅛in.), the initial radius is 1·20m. (3ft. 11½in.), and the final radius 3·73m. (12ft. 2⅞in.). The number of revolutions for one haul is 64. To draw 56 tonnes (55 tons) per hour it will be required to make 25 hauls per hour; it takes 144 seconds to make one ascension, and reckoning 38 seconds for manipulating the machine, there remain 106 seconds for the actual ascension. To prevent the speed from exceeding 15m. (49ft. 2½in.) per second in the pits, a constant angular acceleration is allowed for 15 seconds to reach the rated speed of 42 revolutions per minute in 77 seconds. The stopping is effected in 14 seconds by a constant retardation. The moment of inertia of the two drums, including the brake drum, is 5,606·5 kg.-m.² (133,000 lb.-feet²). The moment of inertia of the motor is 2,548·4 kg.m.² (60,460 lb.-feet²), and that of a head-gear 407·7 kg.-m.² (9,675 lb.-feet²). By the aid of these data the conditions for manipulating the winding machine can be found. The curves (Figs. 1 to 5) may now be drawn according to M. Dechamp's method for flat tapered ropes winding on drums: (1) Curve $A_0 A_{10}$ representing the weight of the rope per metre run as a function of the depth; (2) $B_0 B_5 B_{10}$ representing the weight of the unrolled part of the rope as a function of the depth; (3) $B_0 B'_5 B_{10}$ representing the weight of the unrolled part of the rope as a function of the number of revolutions of the machine; (4) the curve of statical moments $x_0 x_{10}$ of the ascending loads referred to axis C C'; (5) the curve of statical moments $x'_0 x'_{10}$ of the descending loads referred to axis H H'; (6) the invert $x''_0 x''_{10}$ of $x'_0 x'_{10}$ referred to axis C C'; (7) the curve $X_0 X_{10}$ of the resultant statical moments.

* Paper read before the Institution of Mechanical Engineers (translated from the French).

Digitized by Google

Resistances (Figs. 1 and 4).—Besides the statical moments the motor has also to overcome the resistance of the air to the motion of the cages, the frictions in the pit and at the bearings of the head-gears and of the shaft of the machine, and, finally, the resistance of the rope to bending. These various factors may be assimilated to a load suspended at the ascending rope, and whose moment be added to the statical moment. This load has been found to be 15 per cent. of the useful load in the trials made on the electric winding machine at Preussen II. In the absence of exact data, and also for the sake of simplicity, we may take the moment of resistances as constant during the whole hauling, and give it a value equal to 15 per cent. of the maximum statical moment of the loads. The value of the statical moment, including resistances, is measured by the ordinate of the curve $X_0 X_{10}$ by lowering the axis of abscissæ an amount $C K_0$ equal to 15 per cent. of the maximum moment, $C_1 X_1$. To the statical moments must further be added the moments of the accelerating forces required for the moving masses. These masses are fixed to the shaft of the motor and participate in its rotation. The moment of the accelerating forces may be deduced from the moment



Abscissæ Scale.
1 Div. = 100 m. (328 ft.) or 6·4 Revs.

FIG. 1.

of inertia (I) of the moving masses referred to the shaft of the motor, and from the law of rotation of the shaft, as will be shown further on. For the purpose of determining the moments of inertia of the masses, it will be convenient to consider the following: (1) the masses of the loads suspended on the rope; (2) the masses of the rope-rolls; (3) the masses of the head gears; (4) the mass of the drums and pulleys.

Moments of Inertia of the Suspended Loads (Figs. 1 and 4). The suspended loads, P, may be considered as concentrated at the end of the instantaneous radius, ρ, of the rope-roll, which is, therefore, also their radius of gyration. The moment of inertia is then

$$I = \frac{P}{g} \rho^2 = P \rho \frac{\rho}{g},$$

$P \rho$ is the statical moment of the suspended load; it will, therefore, be sufficient to multiply the statical moment by $\frac{\rho}{g}$. The moments of inertia may be found graphically from the values of the statical moments of the ascending and descending loads. It may be noticed that in determining the statical moments, we neglected the lengths of rope between the winding gear and the pit's mouth, which are in equilibrium. But as these lengths are 40m. to 50m. (131ft. to 164ft.), they cannot be neglected in making determination of the moment of inertia. New curves of moments, $P \rho$, must be determined by adding to the curve $B_0 B_5 B_{10}$ the weight of 50m. (164ft.) of rope; we thus obtain $B''_0 B''_{10}$, which serves to determine the curves of moments $y_0 y_5 y_{10}$ and $y'_0 y'_5 y'_{10}$. The latter should be inverted and referred to axis C C'. This operation may be done on the curve of moments of inertia. We proceed as follows: On the ordinate through C, we project the ordinates of the curves $y_0 y_5 y_{10}$ and $y'_0 y'_5 y'_{10}$, and through the projections thus obtained we draw lines to pole D in case of

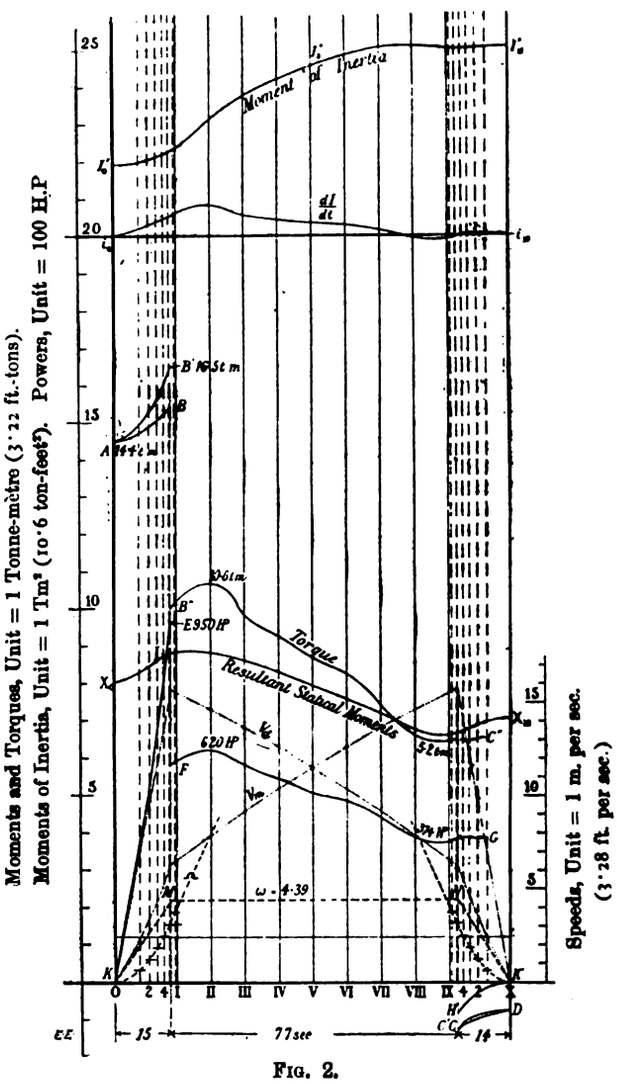


FIG. 2.

curve $y_0 y_5 y_{10}$ and to pole F in the case of $y'_0 y'_5 y'_{10}$. We next calculate one of the moments of inertia that is easy to obtain; for instance, the moment corresponding to the small radius of the rope-roll. We take $\frac{P}{g} r^2$ for the ascending load, its value is $C i_0$; a horizontal line drawn through i_0 intersects the pole-ray D y_0 in a_0; a vertical through a_0 intersects the pole-rays in points a_5 a_{10} a'_0 a'_5 and a'_{10}, these points are then projected on the ordinate through C, and through the projections thus obtained we draw pole-rays emanating from poles D or F as the case may be. To obtain the moments of inertia, $i_0 i_5 i_{10}$ and $i'_0 i'_5 i'_{10}$, of the ascending and descending loads, we produce the pole-rays until they intersect the corresponding radius of the rope-roll. In fact, we have

$$A a_0 = C i_0 = C y_0 \frac{r}{g}; \quad A a_5 = V y_5 \frac{r}{g}; \quad V i_5 = A a_5 \frac{\rho}{r} = V y_5 \frac{\rho}{g}$$

and so on. Curve $i'_0 i'_{10}$ of the moments of inertia of the descending loads referred to axis H H' must be inversed and referred to the same axis, C C', as the moments of inertia of the ascending loads. Curve $i''_0 i''_{10}$ is thus obtained. The moments of inertia of the ascending and descending

Digitized by Google

loads are now added by adding the ordinates of their respective curves. Curve $I_0\ I_5\ I_{10}$ is thus produced.

Moment of Inertia of the Rope-Roll (Figs. 1 and 4).—The weight, P', of the rope-roll may be determined by taking the differences between the weight of rope, O B''_0, and the weight of the unrolled rope represented by curve $B''_0\ B''_5\ B''_{10}$. The moment of inertia depends on the radius of gyration. In the case of winding on constant radius, the radius of gyration is the same as that of the rope-roll, and it is not necessary to consider the different parts of the rope separately. We simply multiply the useful load of the cages and the ropes by $\frac{r^2}{g}$. In the case of conical and spiral drums, the variation of the radius of gyration must be

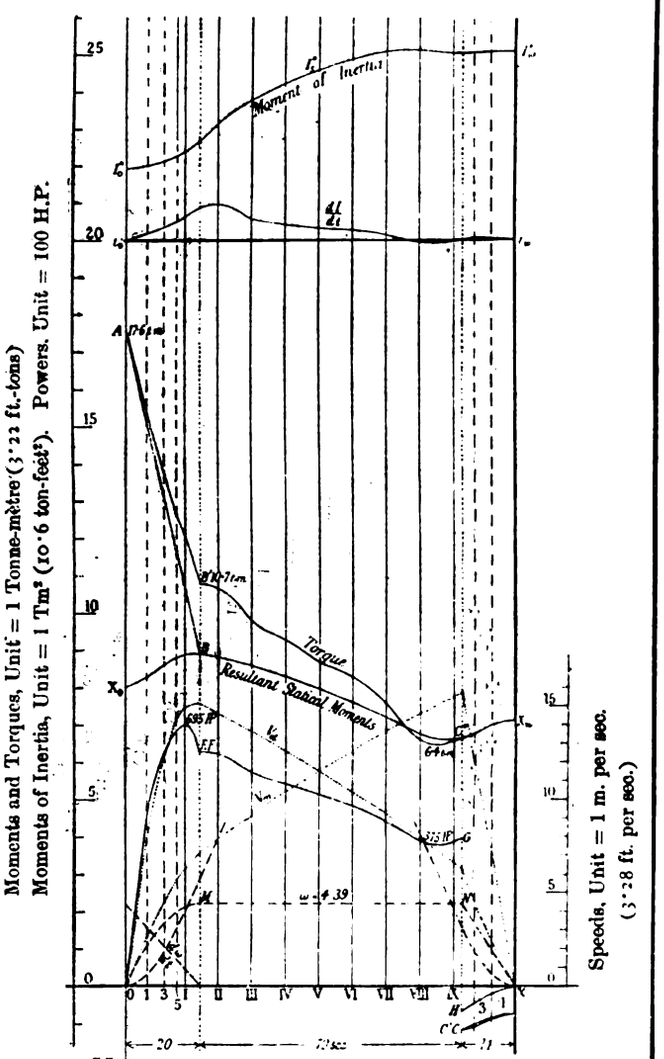

FIG. 3.

taken into account. When the rope is not taper, the radius of gyration of the rope-roll (radius ρ) is $\frac{r^2+\rho^2}{2}$,* where r is the smallest radius of the rope-roll. If the rope is taper, the error committed by not taking into account the decreasing thickness of the rope is negligible. The moment of inertia is determined by multiplying $\frac{r^2+\rho^2}{2}$ by the mass $\frac{P'}{g}$ of the rope-roll. The curves $C_0\ C'_5$ X and O $C'_5\ C'_{10}$, referred to axis O X, represent the moments of inertia of the two ropes. The two curves are identical, but inverted with regard to each other; the sum of their ordinates will give us the total moment of inertia ($C_0\ C_5\ C'_{10}$) of the rope-rolls. The latter moment should be added to the moments of inertia ($I_0\ I_5\ I_{10}$) of the loads, thus determining the total moments, $I'_0\ I'_5\ I'_{10}$ (Fig. 1).

Moment of Inertia of the Head Gears.—The moment of inertia (I_m) of the head-gears may be determined from the drawings. I_m must, however, be multiplied by $\frac{\rho^2}{R_m^2}$, ρ and R m being the radius of the rope-roll and head-wheel rim respectively; the two sets of reduced moments of inertia are represented by the ordinates to curves $m_0\ m_5\ m_{10}$ and $m'_0\ m_5\ m'_{10}$ (referred to O X). These curves are identical, but inverted with regard to each other; by adding their ordinates, the total moments of inertia ($M_0\ M_{10}$) of the head-gears are found. The ordinates to curve $I''_0\ I''_5\ I''_{10}$ (Figs. 1 to 5) are equal to the sum of the ordinates to curves $M_0\ M_{10}$ and $I'_0\ I'_5\ I'_{10}$.

Moment of Inertia of the Winding Gears and of the Motors (Figs. 1 and 4).—The moment of inertia of the drums, brake drum, and gearing may be determined by referring to the drawings. In the case of electric driving, the moments of the motors must be added. The moment of inertia of the winding machinery is constant, and must be added to the moment determined above. This may be done by setting its value C U off from C C' downwards; the ordinates of curve $I''_0\ I''_5\ I''_{10}$, referred to U V as axis

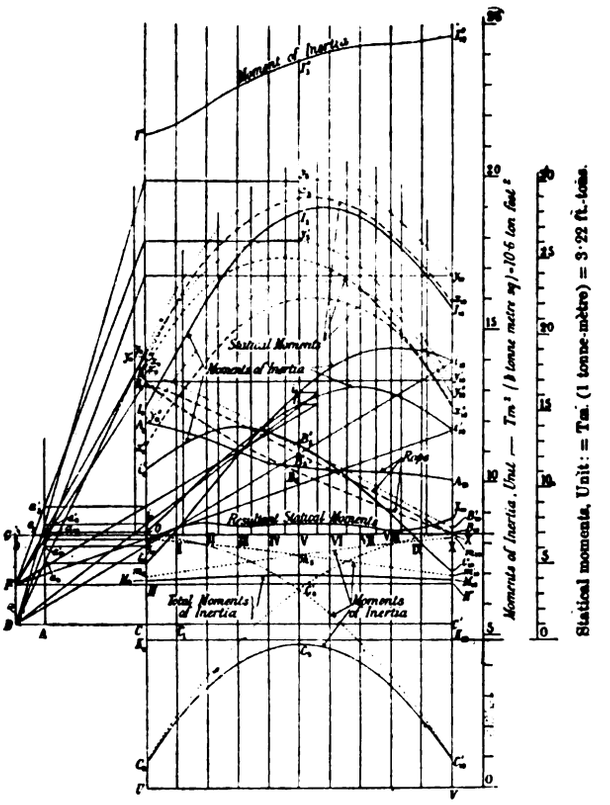

FIG. 4.

of abscissæ, will then be a measure of the total moment of inertia. The curve $I''_0\ I''_5\ I''_{10}$ may be called the "characteristic of inertia" of the winding engine.

Speed of Rotation of Machine Shaft.—The moments of the accelerating forces may be determined by the total moment of inertia and by the speed of rotation of the motor shaft. For this purpose curve $I''_0\ I''_5\ I''_{10}$ must be referred to abscissæ representing time. The abscissæ of $I''_0\ I''_5\ I''_{10}$ are proportional to the number of revolutions made by the motor shaft, and the total number of revolutions of this shaft during each draw is 64, so that each division of the axis of abscissæ will represent 6·4 revolutions. We must also know the time required for each revolution, if the relation between speed and time is to be determined. This depends, however, on the manner in which the machine is manipulated by the driver. There are two simple cases: (1) starting with a uniformly accelerated angular velocity, which implies a constant angular acceleration; (2) starting with a uniformly decreasing angular acceleration. Analogous laws may be adopted during the period of retardation. The first case has been adopted in connection with the data supplied by M, Troussart, by allowing a

* The moment of inertia of that part of the rope which is never unrolled is constant, and may be added to the moment of inertia of the winding gear.

time of 15 seconds to get up a speed of 42 r.p.m, which is an angular velocity, $\omega = \frac{2\pi \times 42}{60} = 4{\cdot}39$ radians per second; the constant angular acceleration is thus $\frac{4{\cdot}39}{15} = 0{\cdot}292$; the rate velocity is maintained 77 seconds, and the stopping is effected in 14 seconds with a constant negative acceleration $\frac{4{\cdot}39}{14} = 0{\cdot}313$. Curve O, M N X (Figs. 2, 3, and 5) represents the variation of the angular velocity. The integral of O, M N X for a given abscissæ, t, represents the total angle, Ω, through which the motor shaft has turned since starting, and by dividing Ω by 2π we obtain the total number of revolutions made by the shaft during time t. The curves which represent the relation between the statical moments (X_0 X_{10}, Figs. 1 to 5) and time, and also between the moments of inertia (I''_0 I''_{10}) and time, can now be drawn, by taking the ordinates of these curves (Fig. 1), which correspond to each revolution.

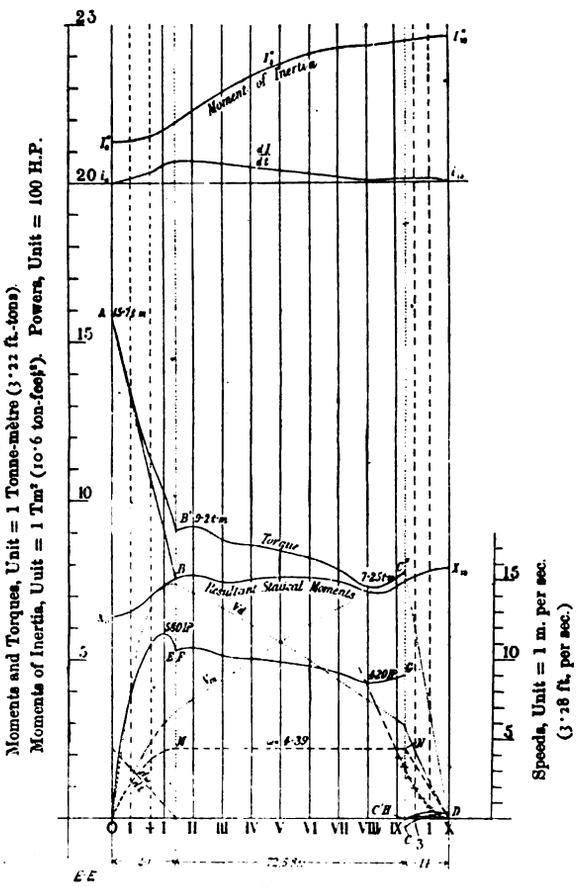

FIG. 5.

Moments of the Accelerating Forces.—The energy exerted by the accelerating forces during time t is $\frac{\omega^2}{2} I$, where ω is the angular velocity at the end of time t and I the moment of inertia (I''_0 I_{10}''). If M be the moments of the accelerating forces, then the energy exerted by these forces during time t may also be expressed by $\int_0^t M\,\omega\,dt$; hence

$$\int_0^t M\,\omega\,dt = \frac{\omega^2}{2} I.$$

As M, ω, and I are functions of t, we obtain by differentiation

$$M\,\omega = I\,\omega\,\frac{d\omega}{dt} + \frac{\omega^2}{2}\frac{dI}{dt},$$

or,

$$M = I\,\frac{d\omega}{dt} + \frac{\omega}{2}\,\frac{dI}{dt}.$$

$\frac{d\omega}{dt}$ is constant during the period of acceleration and retardation, and is zero during the period of constant speed. Multiplying the ordinates of curve I''_0 I''_{10} by the corresponding values of $\frac{d\omega}{dt}$, and then adding the results (algebraically) to the ordinates of X_0 X_{10}, we obtain the portions A B and C D (Fig. 2). For the purpose of calculating $\frac{\omega}{2}\frac{dI}{dt}$, we construct the derived curve of I''_0 I''_{10} graphically. The ordinates of this new curve (i_0 i_5 i_{10}), estimated from the line through i_0 as axis of abscissæ, are now multiplied by the corresponding values of $\frac{\omega}{2}$ taken from O, M N X, and the results are added (algebraically) to the ordinates of A B X_1 X_9 C D. In this manner we obtain the total torque (A B′ B″ C″ C′ D, Fig. 2) which must be exerted by the motor at any instant. It will be seen that the torque varies considerably. It attains a maximum of 16,500 kg.-m. (119,345 ft.-lb.) at the end of the period of acceleration, and then suddenly drops to 10,000 kg.-m. (72,330 ft.-lb.) at the beginning of the constant speed period; during this period the maximum value is 10,600 kg.-m. (76,670 ft.-lb.), and the minimum 5,200 kg.-m. (37,612 ft.-lb.). The torque is negative during the period of retardation.

Power and Expenditure of Energy.—The torque of the motor multiplied by the corresponding value of ω is the power which must be developed at each moment. This power is represented by curve O, E F G H X (Figs. 2, 3, and 5), the integral of the latter is the energy spent during each draw. At the end of the acceleration period the power attains a value of 950 h.p., whilst during the constant speed period it varies between 620 h.p. and 370 h.p.; the latter figures differ from those found by M. Troussart, which have undoubtedly been found by a less exact method than the one adopted by us. The case of uniformly decreasing acceleration has also been treated; the results are indicated by the curves Fig. 3, which are marked with the same letters as the corresponding curves in Fig. 2. It may be noticed that the curve O M, which represents the variation of the angular velocity. ω, during the acceleration period, is the integral curve of the straight line which represents the variation of the acceleration $\frac{d\omega}{dt}$. It will be seen that although a rather greater torque is required during the acceleration period, which is not difficult to obtain with an electric motor, the power required varies much less. It would, therefore, be advantageous to start the machine with a decreasing acceleration. It might be asked whether the power would not be less variable if the radii of the rope-roll were chosen so as to make the statical moments less regular. We have treated the machine at Grand Hornu with regard to this question, for $r = 1{\cdot}10$m. (43·4in.) instead of 1·20m. (47·24in.). The results are shown in Figs. 4 and 5, the same letters as on Figs. 1 and 2 being used all through. It will be seen that the power diagram is much more regular. The ordinates of the power diagrams which we have determined should be divided by the efficiency of the motor so as to obtain the total power spent; the integral of the latter curve would give us the total energy required. The useful work divided by this energy is the efficiency of the winding machinery. The efficiency of electrical motors differs with the kind of motors and their starting devices.

(To be continued.)

APPOINTMENTS VACANT.

Engineer-in-Charge, Bermondsey. Salary, £2.

Assistant Engineer about 25 years of age, with good knowledge of mechanical engineering. Applications to G M 532, Messrs. Deacon's, Leadenhall-street, London, E.C. See advertisement.

Practical Engineer to supervise the equipment of a complete electrical tramway in India. Applications to Box No. K 10, *Electrical Engineer* Office. See advertisement.

Assistant Buyer in electrical engineering works in Midlands. Applications to Box G 49, *Electrical Engineer* Office. See advertisement.

Youth (smart). Applications to the Electrical Co., 121-125, Charing Cross-road, W.C. See advertisement.

LONDON TRAFFIC.

The event of the week is the issue of the first volume of the report of the Royal Commission on London Street Traffic, though, on the other hand, some may think the rejection of the London County Council Bill by the House of Lords more important. It may, however, be found that the two events are more or less interconnected. Whatever may be the opinions held by other men, nothing is more certain than that the Commission's majority report is definite and drastic. A minority report, which is far more consonant with our views, is presented by Sir G. C. T. Bartley, while Sir G. S. Gibb, who signs the majority report, does so with an explanatory note. A quarter of a century and more ago the present writer suggested a careful examination of this subject and the formulation of a unified scheme, so that extensions in every direction should relieve, and not add to, the congestion of traffic. Since that time the population has increased from about four and a half millions in Greater London to about six and a half millions. Had a scheme of main roads and streets been at that time designed and made compulsory, we should hear very little about congestion now; but things went on as they were, and it needs little foresight to know will continue to go on in the same happy-go-lucky way in future, this report notwithstanding. We fear, indeed, that this report will have the effect of increasing congestion rather than the contrary, in that, supporting as it does large ideas of tramway extension, these extensions will to some extent take place where the conditions are really not favourable to tramway work. By all means extend tramways where the conditions are favourable, but do not accept the views that they are satisfactory under all conditions. The rejection of the London County Council Bill brings about a condition of affairs little short of a crisis. Congestion of traffic during certain periods of the day at the dead end of the lines south of the bridges, and the danger to life and limb occasioned by the rush to and from the cars and from other traffic, has reached the final stage. This position of affairs was foreseen, and whether the public agrees or not to passage across the river, that passage must come about, or the usefulness and extension of the tramway lines cease. We think the London County Council has been very wrongly advised in some of its extensions, but that does not help matters. But to the more important topic—the report. The gist of the report is summed up in the phrase: hitherto divided counsels and control, in future a central authority. Much as the creation of new spending departments may be disliked, there can be no two opinions as to this suggestion of the report. Traffic to be dealt with properly must be dealt with as a whole, and this means one supreme authority for the area of Greater London. Unfortunately, the report suggests a board that should be consultative and advisory only, though its decision would be final, and the veto of existing authorities would be subject to such decision. The arguments relating to working-men housing and such like things in this report if given in a Shaksperian play would be reckoned farcical. It is astounding to what length politicians and place seekers will go when dealing with the working classes, and the whole means fishing for votes. Economical laws are lacking, or are summed up in the phrase: it is expedient to make friends with the voting *oi polloi*. Take as a sample the implication that a workman must not work more hours than a maximum; he may waste two hours a day, more or less, in a train or tram, he may spend fourpence a day for his ride, and he cannot pay more than a certain amount for his rooms. Of course not; but, taking

Digitized by Google

the extreme, shorten his hours of work, take him a longer ride further out to a less expensive room at a greater cost per ride, and will that help the workman? In other times the argument was get the workman to live as near as possible to his work; now it is get him to live away—it will be good for the tramway and for the workman. It is assumed that the economics of the factory are elastic, and, in fact, that factories can be established anywhere. The craze of the workmen's advocate says the man first—the factory after. The economic law says the man is only a factor in the factory economy, and other factors being all right there will be no difficulty about the man. All that is good in this report is easily summarised — thus a useful lot of information and the dealing with natural areas by one authority. There is no doubt the most valuable suggestion is the supreme board, and it is in this direction, if anywhere, that good will result from the labours and expenditure of this Commission, but such board must be given power to initiate as well as to advise.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

MUNICIPAL WIRING.

SIR,—I should esteem it a favour if you would allow me, through the columns of your valuable journal, to thank those gentlemen who so kindly volunteered to come forward and give evidence on behalf of the contractors against the London County Council General Powers Bill.

Thanks to the solicitors engaged, our case was presented in such a manner before the House of Lords that the committee decided to strike out Part 12 of the Bill entirely—that is, the whole of the clauses relating to municipalities carrying on the wiring work themselves.

You may remember that in 1903 similar clauses were introduced into a Bill by the London County Council, and that we were then successful in getting the House of Commons to move an instruction that they should be cut out. This year we were unsuccessful in the House of Commons, but successful in the House of Lords, and our success is in a great measure due to the opposition we were able to make owing to the good evidence volunteered and to the money subscribed by members of the electrical profession generally outside of our association.—Yours, etc., LEONARD G. TATE,

Hon. Secretary, Electrical Contractors' Association.
20, Bucklersbury, E.C., July 17, 1905.

LONDON TELEPHONE DIRECTORY, 1905-6.

SIR,—We beg to state that through a mistake on the part of the National Telephone Company our name and telephone number were not inserted in the above. In order to overcome this difficulty we have had small labels with gummed backs arranged for easily pasting into the space that is available for our name, in such a way as not to interfere with any of the other names in the telephone directory. We shall be pleased to send these immediately on receipt of an inquiry by telephone or otherwise.—Yours, etc, UNION ELECTRIC COMPANY, LIMITED

151, Queen Victoria-street, E.C., July 18.

RAWORTH REGENERATIVE CONTROL.

A demonstration of this system of tramcar control was made in the Birmingham district last week on the Station-street-to-Yardley route. The distance of four miles has gradients varying from 1 in 16 to 1 in 20 for 3½ furlongs, and the whole route is hilly. Thus it showed the full advantages to be derived from the system. A full description of the Raworth control will be found in our issue for July 29, 1904. We propose here to confine our remarks to the improvements made since that date, and to the records obtained on the Birmingham tramways. There the Raworth control has been in use since March, and has reduced the energy required per car mile from 1·3 units with series motor to 0·97. The brake blocks repairs averaged ·005d. per car mile, as against ·063d. with the previous equipments. The average temperature of the motor windings after 18 hours' service is about 140deg. F. with the shunt motors, as against 120deg. F. for the series motor. As to the repairs to motors and controllers, the period of trial has not been long enough to give any comparative figures.

The feature of the demonstration was a car on which the series-parallel control has been introduced with shunt motors for the first time. The electrical details of this equipment have been designed by Mr. Raworth's son, and particulars as to the same were not available. The trial showed, however, that the changes from series to parallel, and *vice versâ*, were made without any sudden acceleration on braking of the car, and without sparking at the brushes on the motors.

At Yardley those attending the demonstration were shown the generating station equipped with four Diesel engines, each of 160 h.p., coupled to direct-current dynamos. At a lunch which followed Mr. Raworth explained the advantages of the system of control, and the great saving which it effected over the older methods of driving cars electrically.

NOTES ON THE INDUCTION MOTOR AS GENERATOR.*

BY T. P. E. BUTT.

It has been known almost from the initial invention of the asynchronous alternating motor, generally known as induction motor, that, if connected to its supply mains and driven at a slightly higher speed than synchronism, it reverses its usual function and becomes a generator. This knowledge, however, does not appear to have been put to any extensive use, at least not in a commercial sense†, and even in cases where applied, very few details are obtainable to allow one to form an opinion of the actual value of such machines.

There is another point in such machines equally interesting, and perhaps more useful, demonstrated by Danielson, and published in the *Elektrotechnische Zeitschrift* about two years ago. He described a method of converting an alternating-current motor from asynchronous to synchronous, by suitably exciting the rotor with continuous current. This is a point for which much use should be found, for such machines, in addition to possessing the inherent qualities of the synchronous motor, are self-starting. In order to effect this the motor is started up as an induction motor on light load, so that its speed approximates synchronism. At the right moment the rotor lines are switched over from the resistance to a suitable source of continuous current, which pulls the rotor into synchronism, and maintains it at this speed. Such machines should be of use on inductive systems to raise the power factor, where such an inflexible arrangement as the ordinary synchronous motor may not find favour.‡ Circumstances having placed the writer in a position to test the above principle, he assumed that the converse would hold good—that is, if power were applied to the rotor shaft, and its windings supplied with continuous current, the outcome would be a successful generator. The results are given in this paper, and, although not obtained under favourable conditions, are of interest.

About two years ago, when it was decided to augment the lighting supply of Johannesburg from the electrical plant of the Robinson Deep G.M. Company, it was found necessary to obtain an additional generator to provide a reserve for the existing plant, in case of accidents and to

* Paper read before the South African Association of Engineers on May 6, 1905.

† Induction motors are used for electric traction on mountain lines. When descending a hill electricity is forced back into the trolley wires, and a braking effect is produced, the machine acting as a generator.

‡ This method might be noted in connection with the electrical driving of stamp batteries.

Digitized by Google

allow for general repairs. The management did not at first fall in with this idea, and the project temporarily fell through. It happened, however, that a 300-h.p. 2,000-volt induction motor, originally intended for operating a hoist, had been laying dismantled on the property for several years, and the suggestion of the writer to convert this into a generator was entertained and adopted. It should be explained here that the generating plant consisted of two direct-coupled three-phase 250 kw. machines working at 2,100 volts 60 cycles, and the power demand was such as to require one generator constantly running, the second assisting on the peak of the load for several hours during the day, whilst from 4.30 p.m. till midnight this second generator was loaded and often overloaded for the municipal supply, and although in case of accident to either generator the mine requirements would have had first consideration, the town supply was sufficiently remunerative to warrant the installation of another machine. Owing to the difficulty in getting at short notice an engine suitable for driving this machine, it was arranged to operate it from one of the mill engines, a 500-h.p. single-crank compound engine having at that time a surplus of about 300 h.p. A friction clutch and pulley were attached to an extension of the line shafting and rope drive provided. This necessitated the location of the generator in a wing at the extreme end of the power-house, in a position invisible from the main switchboard.

To use the generator asynchronously involved very little alteration to the existing apparatus. The windings, of course, remained the same, but it was necessary to make provision for a variable speed for this machine, which, unlike the ordinary generator, requires a slight increase of speed to take an increased load. To get a variable speed from the mill engine was out of the question, and recourse had to be made to other means—viz., magnetic slip. This demanded the installation of the huge rheostat which originally formed the controller. This method would not be an efficient one if constantly used, but this was not intended, its use being restricted, as a rule, to the short period of time required in putting in or taking out of parallel with another generator to regulate the transfer of load. This arrangement demanded a permanent increase of speed above that of synchronism, and an increase of 5 per cent. was allowed, which was as much as possible, taking independent working into account. The controller was located near the generator, and operated by motor from switchboard, the position of its axle being indicated by luminous signals. The arrangements for asynchronous running were practically complete, but for independent working an exciter was required suited to the rotor winding, and for this purpose a disused plating dynamo was found having a capacity of 600 amperes at 30 volts. A low-tension panel was located near the generator, and the rotor windings brought to it, provision being made for rapidly connecting them to either the exciter or controlling rheostat.

It may be opportune at this point to give a short non-mathematical explanation of the action of asynchronous generators, which differs in some points from that of the regular generator, and is not generally understood by practical men. Taking the ordinary polyphase induction motor, here we have a shifting magnetic field in the stator, as a resultant of the combined action of the primary currents. The torque on the secondary (usually the rotor) due to currents generated in its conductors by cutting this flux, is proportional up to a certain limit to the difference in the relative speeds of the primary flux and the revolving element, and is practically proportional to the load. Beyond this limit the torque starts to fall off, owing to magnetic leakage caused by the heavy currents in rotor and stator, and if the load is not reduced the rotor comes to rest. If such a motor is now connected to the supply mains on no load, it will attain a speed practically equal to that of the primary field, the slight difference being necessary to allow sufficient cutting of flux to generate currents in the rotor of the magnitude required to overcome windage and friction. These currents will be in a direction tending to diminish the relative motion of primary field and rotor. If power is now applied to accelerate the rotor shaft, then, as it approaches synchronism, the current will diminish, until at synchronous speed the working component nearly vanishes, leaving a wattless current, and we have practically an unloaded transformer, the bigger magnetising current being due to the air-gap and the disposition of the winding, this current being just sufficient to magnetise the core to the extent required by the back E.M.F. Now, still keeping the primary connected to the mains, increase the rotor speed, its conductors again cut the primary flux, but in an opposite direction. The currents now generated, instead of utilising their energy in wiping out the primary magnetism, the source of the back E.M.F., are reversed and reinforce it, thus tending to raise the stator back E.M.F. above the forward, and force current back into the line. If the rotor speed is still further increased more currents are induced, the stator back E.M.F. tends still further to rise, and more load will be taken; and if the capacity of this machine is sufficient and has the necessary power behind it, the load on the system will be transferred to it, and steam can be shut off the regular generator or generators supplying the system, upon which they will continue to run as motors, and supply the magnetising current.

Now, compare some of the characteristics of this machine with that of the ordinary synchronous generator. The expression (pairs of poles by revolutions per second) will not give the correct frequency, but higher, the difference being due to the relative motion of the secondary conductors with reference to the primary field, which must occur to produce the rotor currents, or in other words, this is the negative slip; and the amount of this slip to assume a certain load will depend on the rotor resistance. The frequency will be determined solely by the currents supplied it by the synchronous machine regardless of its own speed. The speed, however, must not rise above a certain critical value, or the power required from the prime mover will fall off rapidly, due to magnetic leakage, as in the case of the motor. Provision then must be made for this in governing the engine, or should this point be exceeded the engine might run away.

Another point, the power factor. This will be dependent on the amount of load supplied to the system, but independent of the nature of such load, so that any currents demanded by apparatus employed on the system not in phase with the working current must be supplied by the synchronous machine. Paralleling is, of course, a simple matter, there being no need for synchronising; it is always better, though, to get the speeds as near as possible to avoid disturbance to the system, if the machine is of large relative capacity. The possibility of running such machines for boosting purposes, as suggested by M. Le Blanc, will not be touched on here, but is mentioned as another addition to its area of usefulness.

Now, turning to another function of this machine. The synchronous part of the operation requires little or no explanation; the rotor is simply transformed into a field magnet with a continuous iron surface, instead of the usual definite polar projections. Anticipation of serious magnetic leakage in this method can be referred to results. The first trial took place under asynchronous conditions; the machine, it should be stated, has a distributed winding, three slots per phase per pole in stator and four in rotor, the number of poles being 24, so that the permanent speed was 315 revolutions, or 5 per cent. above synchronism at 60 cycles. At this speed or near it, and with the rotor resistance all in circuit, the switch was closed on the 'bus bars, thus paralleling it with a synchronous generator which at the time was delivering 90 kw. A current equivalent to 30 per cent. of the non-inductive full load current was taken, and under these conditions the disc movement of a sensitive watt-hour meter in circuit was scarcely perceptible; the resistance was then cut out, until the whole load was taken, and steam was then shut off the synchronous machine, which continued running as a motor. After this steam was again admitted and the load increased and distributed by means of the rheostat on the two machines until a combined load of 362 kw. was carried, out of which the induction machine supplied 170 kw. This was the limit attained and was determined by the speed of the mill engine, which was not well governed, and at this point became unstable, thus causing sudden transfers of load between the generators, and big voltage variations. A

Digitized by Google

higher limit would have been obtained with a more favourable load—that is, motors of relatively small capacity or lights—but nothing less than 50-h.p. motors were available, and the switching on of such at this stage would cause a marked fall in speed of the mill engine, upon which heavy surgings of current would take place, knocking the voltage beyond control and dislocating the service.

The machine was next tried as an independent generator. More interest was attached to this test, as if the operation proved successful, this method of working would have considerable commercial valve. Two methods of exciting the rotor were available, either by cutting out one branch of the winding altogether, and connecting the other two in series to form the path for the current, or by connecting two branches in parallel and putting the combination in series with the third. This latter method was found to be more economical in exciting current. The trials under these conditions and with an induction motor load resulted in attaining an output of 180 kw. before the engine governing gave trouble. The excitation at this load was 7 kw. On a lighting load the results were extremely satisfactory, the output limit being largely increased—in fact, on certain occasions of big demand at the municipal lighting station, loads up to 315 kw. have been delivered with an excitation of 330 amperes at 25·5 volts. The engine under this load had got beyond governor control and fallen 4 per cent. in speed, but beyond this showed no signs of distress. This load, however, was abnormal, the maximum seldom exceeding 260 kw. The excitation required at no load was 138 amperes at 9·5 volts, or 1,311 watts as against 27 amperes at 133 volts (3,591 watts) for the regular generator. At loads of 180 kw. on similar power factors of approximately ·75 the excitations were 6·4 kw. and 5·2 kw. respectively; here the longer air gap of the regular generator tells to advantage. On similar loads (lighting) of 220 kw. the order is reversed, the regular generator requiring 5·2 kw. against 4·5 kw. of the converted machine.

The results on the whole must be considered good. With a constant speed at the prime mover, higher limits would have been reached on motor loads; part of this was due to the governing, but large steam pressure fluctuations played no inconsiderable part, and this was in a measure unavoidable, owing to the fact that two large winding engines were supplied from the same battery of boilers. The excellent results obtainable on non-inductive loads, neglecting the part due to less armature reaction, were attributable to the gradual assumption of the load, under lighting conditions, as distinguished from the sudden changes caused by switching on motors of large relative capacity, when on inductive loads. The temporary pulling up of the prime mover under the latter conditions was, of course, noticeable on lighting loads when heavy banks of lamps were thrown on; but this occurred very seldom, and it is obvious that, although inconvenient in such cases, it had not the dangerous factor which such occurrences might mean to motor loads. This machine offers another field of usefulness as a motor, and with its present connections can be used in case of emergency to drive half the mill (100 stamps), no change at all being necessary beyond disconnecting the mill engine.

To sum up, then, it must be admitted that under the disadvantageous conditions prevailing, good results have been obtained as far as the object in view was concerned. With more power at our disposal, and under our own undivided control, still better results could have been looked for on inductive loads. Asynchronous working increased either generator capacity by about 45 per cent., and was sufficient to tide over the peak of the day load. The heavy wattless current is a serious trouble, and reduces to a great extent the advantage obtained in other directions. It could be neutralised by the use of a static condenser, but condensers of the size necessary here (capacity 35 microfarads) can scarcely be called commercial apparatus, and would be expensive and difficult to obtain here.* Independent working was certainly a success, and up to the time of the writer leaving the company it was nearly always used as such. The short air-gap and low flux density in the rotor, although favourable as a motor, allowed a big armature reaction when generating on inductive loads, but the effects of this would not have been so noticeable with automatic voltage regulation, such as, say, the Tirrell system. As to the use of such machines in mining districts, such as the Witwatersrand, it depends entirely on circumstances. No doubt in the near future isolated electric generating plants will disappear, and be replaced by central supply stations, operating over suitable areas. When such a system is actually in sight, any immediate addition to the generating plants of mines likely to be affected by the change could be provided for by a machine such as described, which, on conversion of the systems, could at once resume its original *rôle* as a motor.

* Mr. Alexander Russell informs me that he has condensers for 500 volts working (four in series for 2 000 volts, costing £1 per three microfarads) at Faraday House, London, supplied to him by the Stanley Manufacturing Company, of America.

A LIGHTNING ARRESTER RELAY.

The small spark gaps required in lightning arresters protecting comparatively low voltage (under 5,000 volts) circuits has always been a source of unreliability in their action. This is partly due to the bridging of the small gaps by dust, insects, etc., and partly to the fact that, at least in the horn type of arrester, the current at which the arc runs up the horns and extinguishes itself increases as the gap is reduced, so that with very small gaps—such as a 1mm. gap, corresponding to a sparking voltage of about 3,400—the large current is sufficient to melt the edges of the horns partially, and so interfere with the exact setting of the gap. One of the simplest ways of increasing the gap depends on the influence of ultra-violet rays on

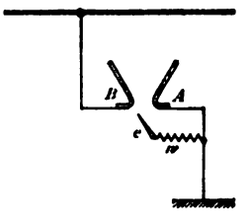

Fig. 1.

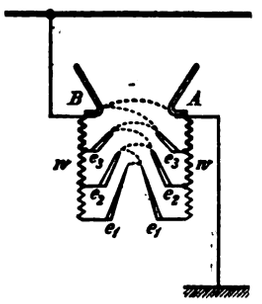

Fig. 2.

the sparking distance in air. Usually the ultra-violet rays are produced by a small auxiliary spark gap placed quite close to the main gap, and preferably arranged so that one pole of the main gap also forms one pole of the auxiliary gap (Fig. 1), whilst the other pole of the auxiliary gap is connected to the other pole of the main gap through a high resistance. Sometimes two or more auxiliary gaps are employed, each longer than the last, and arranged so that the sparks start across the shortest gap and then jumps across each of the other gaps in turn, and finally bridges across the main gap (Fig. 2). In this way the sensitiveness to dust, etc., of the main gap is reduced, but the auxiliary gap is now liable to these troubles. There is, however, a certain advantage in the arrangement, for whereas the poles of the main gap cannot safely be given a sharp or pointed form owing to the large arc rapidly burning them away, the auxiliary spark, owing to the small currents dealt with, can take place between pointed electrodes, and this, as is well known, leads to a marked increase in the permissible gap for a given voltage.

Various other solutions have been suggested, but without any very definite success. Recently a piece of apparatus, based on a new principle, has been devised for the same purpose by the Siemens-Schuckert Company.* It is known as a "lightning arrester relay," and would seem to get over most of the difficulties. The action depends on the artificial production of a higher voltage than that against which protection is sought, this higher voltage being made to break down the resistance of the main gap. The connections for this arrangement are shown diagrammatically

* See A. Dina in *Elektrotechnische Zeitschrift*, May 25, 1905.

Digitized by Google

in Fig. 3, where W is a damping resistance connected to earth through the main spark gap, B, A, and also through an auxiliary resonant circuit in parallel with the main spark gap. The auxiliary circuit contains a small air-gap, F, which is readily bridged by the voltage rise in the line, whether this voltage is of a rapidly fluctuating nature such as is produced by a lightning stroke, or increases slowly as in the case of the gradual accumulation of a static charge on the line. As soon as the spark across F takes place rapid electrical oscillations are set up in the auxiliary circuit consisting of the spark gap, F, the two condensers, C and C_1, and the primary coil, P, of the Tesla transformer, of which S forms the secondary. These oscillations produce a high voltage in S, which is connected at one end direct to the main spark gap, and at the other end to the other pole of this gap through the condensers, etc., and this voltage breaks down the resistance of the gap and so permits the line to discharge to earth, in spite of the fact that the voltage difference between line and earth is too low in itself to span the main gap. At the same time the high voltage set up in S is quite harmless to the installation, because it occurs between earth and one horn of the arrester, and becomes neutralised in the auxiliary circuits containing the condensers without affecting the potential of the line. Even if this were not the case, the capacity of the line to earth would practically act as a short-circuit towards the very high-frequency currents and small amounts of energy dealt with in the Tesla transformer.

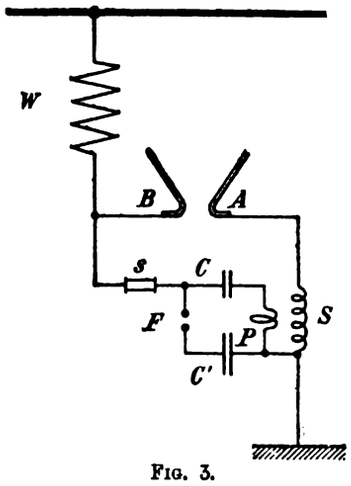

FIG. 3.

Under these conditions the main gap can be set at a reliable length of 3mm. or 4mm., and the auxiliary gap, F, though small, can be made quite reliable and free from outside disturbance by completely enclosing it in a tube, for there is no longer any need for the auxiliary gap and the main gap to have a common pole, or even for them to be situated close together.

As actually constructed, the condenser C, which is permanently subjected to the circuit voltage, is given a capacity of about ·005 microfarad, and for a 3,000-volt circuit is arranged to withstand a breakdown pressure of at least 12,000 volts. Condenser C_1 is only under pressure during a discharge, and so is arranged for a somewhat lower breakdown voltage, and is given a capacity of about ·01 microfarad. The secondary, S, of the Tesla coil consists of 20 turns wound into an 8cm diameter spiral, and has a low self-induction coefficient of only about 25×10^{-6} henrys. It is placed inside a porcelain tube, and the primary, P, which consists of only one turn, is placed outside this tube.

In order to avoid any risk of damage due to the breaking down of a condenser, a fuse is placed at *s* which cuts out the auxiliary circuit, but not the main spark gap, in the event of such an occurrence.

THE ADMINISTRATIVE COUNTY OF LONDON AND DISTRICT ELECTRIC POWER BILL.

(*Continued from page 60.*)

We chronicled last week the opening day's proceedings before the Select Committee of the House of Commons, consisting of Sir James Kitson, Sir Herbert E. Maxwell, Mr. Frank Edwards, and Mr. John Rutherford.

When on Friday last Mr. Honoratus Lloyd, K.C., commenced to resume the examination of Mr C. H. Merz, counsel for the London County Council, the City Corporation, and some of the local authorities applied for particulars of the purchase clause which the promoters were prepared to offer, as no information had been furnished as to period, proposed assignees, or terms

Mr. LLOYD replied that he imagined this would be a question for the committee to settle.

Counsel for the opponents insisting upon their application, the committee held a brief conference, after which the Chairman announced that it would be necessary for the promoters to outline their proposal as early as possible.

Mr. MERZ's examination was then resumed. He stated that a scheme of this magnitude needed to be specially designed; the comparatively small capacity, and the geographical situation of the existing undertakers' generating stations, rendered them quite inadequate for such a purpose. With the plant proposed by the promoters a high diversity of power load would be practicable. In the existing stations the capital charges accounted for 50 per cent. of the total cost of generation. What was a bad load factor with them would become a good one taken in the aggregate. He repeated his evidence before the Lords' Committee to the effect that a station with a capacity of 90,000 kw. could be installed at the rate of £8. 4s. per kilowatt, against an average of £50. 5s. for the existing stations. There would also be a saving on management expenses and wages, and on coal, oil, and stores. One-third to one-quarter of the existing stations were non-condensing, while another third could only condense by the aid of cooling towers. The comparisons in regard to coal took into account varying calorific values, 11,000 British thermal units per ton being allowed for Tyne coal and 15,000 for Welsh. The tables under this head were based upon the average prices of the last 15 years, and a margin of 30 per cent. was added for a possible rise. Steam-turbines of 20,000 h.p. capacity would be used as prime movers, and up to this size their efficiency increased with the size. There was an economy in space, wages, and maintenance. It was proposed to have the first section of the scheme (90,000 kw.) completed by 1910, and the whole four or five years after. The promoters estimated that in the industrial area they would be able to supply two-ninths of the total energy generated by them as follows: one-ninth to existing undertakers, and one-ninth to power users direct. They did not propose to lay a triplicate system of mains in the non-industrial area at once. He repeated the figures as to costs of operation and as to income given before the Lords' Committee, of which we gave particulars at the time.

Cross-examined by Mr. Lewis Coward, K.C., on behalf of the London County Council, he stated that he did not consider the fact of the Council having a vested interest in the municipal electric lighting undertakings to the extent of some three millions constituted a reason why the measure should not pass, as he regarded this as a comparatively small consideration in relation to the great industrial interests at stake. He did not agree that the decision of Lord Cross's Committee when considering the early Power Bills was hostile to the purposes of the present Bill. He denied that the County of Durham Electric Power Company had absorbed municipal undertakings. What the company did was to enter into arrangements whereby districts hitherto unprovided obtained a supply of current, the undertakers having, with the exception of Gateshead, failed to furnish a supply, although powers had been obtained. When asked whether he was aware that the London County Council presented a Bill for co-ordinating the existing undertakings, Mr. Merz became the examiner, and inquired whether this included the companies, to which Mr. Coward replied in the affirmative. Asked on what ground the promoters based their application for exemption from the London Building Act, Mr. Merz replied that both economy and security would be effected thereby. The promoters, in preparing their estimates, had assumed that the tramway undertakers in the Metropolis would not take power from the

Digitized by Google

company for their present requirements, but they might for future extensions, and substantial custom was expected from the railways as they electrified their suburban lines. He assumed that the existing electric light undertakers, as business men, would in a large measure take energy from the promoters because it would be cheaper. He could not quote a precedent for laying down a generating plant at the rate of £8. 4s. per kilowatt, for the simple reason that the present scheme was without a parallel in this country. If exemption from the Building Act were not secured, it would add from £1 to £2 per kilowatt to the price. He was briefly examined as to carrying the mains under the Blackwall and Millwall tunnels, which have special protective Acts in their favour, but it was understood that this matter would be gone into fully on the examination of Sir Alexander Binnie.

The committee then adjourned.

On Monday, July 18, the cross-examination of Mr. C. H. MERZ was continued by the various counsel representing the opponents to the Bill. The fact that the city of London was in the non-industrial area, and that it contained no tramway, railway, or docks that could not be supplied from outside, was urged as a reason for striking the area out of the Bill. Mr. Merz could not agree to this, as some cable route through the City might be found advantageous. He considered that the clauses of the Bill prevented undue competition with existing undertakers. This company had power to buy up an undertaker. If this were done in a district where there were two competing companies now, he considered that the Board of Trade could still protect the remaining undertaker. Mr. Baggallay was cross-examining on this point on behalf of the Charing Cross and City Company, when

Mr. BALFOUR-BROWNE stated that negotiations were going on between the County of London Electric Company and the promoters of this Bill, which he hoped might result in an understanding. He, therefore, reserved the right to defer his cross-examination until the negotiations were completed or dropped.

Mr. BAGGALLAY then asked if negotiations with the City of London Company were also in progress.

Mr. MERZ said a letter had passed as to why the Bill was opposed, but that this letter had not been answered. The Electric Power Development Company were the promoters of the Bill, and they had powers to buy shares in other companies. They might acquire control of any other company in that way. In that case the energy supplied for lighting would not be taken into account when making the average price for dividend purposes. Neither would the revenue from stand-by charges other than for power actually supplied.

In the course of the hearing the following draft of the promised purchase clause was handed in:

Clause 79a, p. 43.

In the event of any public authority or body of trustees (hereinafter called the "purchasing authority") being authorised to acquire the undertaking at the expiration of a period of 50 years from the passing of this Act, and of subsequent periods of 10 years thereafter, the following provisions shall apply and have effect—that is to say:

1. Twelve months' notice in writing shall be given to the company by the purchasing authority intimating their intention to acquire the undertaking.

2. The price to be paid by the purchasing authority to the company shall be a sum equal to the amount standing in the books of the company at the date of the purchase as representing the capital expenditure of the company as audited in the manner hereinafter provided, and without any allowance to the company for compulsory purchase or for the goodwill or prospective value of their undertaking.

3. For the purposes of the immediately preceding sub-section the accounts of the company shall be annually audited by an auditor to be appointed by the Board of Trade, and a copy of the accounts as audited shall be filed with the Board of Trade.

4. The purchasing authority shall also pay to the company for the materials and stores on hand at the date of purchase a price to be agreed on, or, in case of difference, to be determined by an arbitrator to be appointed by the Board of Trade, and in addition the value of the debts due to the company, and the company shall discharge all debts due by the company at the date of purchase and all liabilities with respect to any debenture stock or mortgage debt of the company.

5. The expression "undertaking" shall for the purposes of this section include all rights of generating, purchasing, using, transmitting, transforming, distributing, supplying, and utilising energy and all other rights, powers, authorities, and privileges of the company, and all such property real and personal, and all other interests and rights in, to, and out of the property real and personal, and obligations and things in action as may be in the possession of the company or belong to them immediately before the date of purchase, and all books, accounts, and documents relating thereto, but subject to all liabilities and obligations of the company other than the debts due by the company, and the liabilities with respect to the debenture stock and mortgage debt of the company.

6. As from the date of purchase the undertaking shall be transferred to and vested in the purchasing authority, and such authority shall have and may exercise all the rights, powers, authorities, and privileges of the company, and shall to the exclusion of the company be subject to all the duties, obligations, agreements, and liabilities of the company in like manner as if they were the company, except the debts due by the company at the date of purchase, and the liabilities with respect to the debenture stock and mortgage debt of the company.

The clauses embodying the agreements with the municipal undertakers of Stepney, Bexley, and Barking, referred to in our last issue, were also handed in, as was the agreement with the Kent Power Company. The arrangement with the Stepney Metropolitan Council is contained in Clause 85A, which has 18 sub-sections. The agreement is for 50 years, subject to option to terminate at the end of 25 years with compensation for the unredeemed portion of the plant and mains of the company less than 25 years old appropriated exclusively to the supply of energy to the Council. The sub-sections read as follows:

1. The company shall not supply energy within or for use within the metropolitan borough of Stepney except to the Council and to any railway company for the purposes of their railway.

2. Subject as hereinafter provided, the Council shall purchase in bulk from the company all the electricity which the Council may require beyond that which their present existing generating station is capable of furnishing within the dimensions of the present building.

3. The Council may maintain in efficient working order and make improvements and additions to the plant installed or to be hereafter installed at their present generating station and works and as regards auxiliary plant whether inside the existing building or not, and they may use the said plant to its full capacity before being required to take a bulk supply from the company as aforesaid, but the Council shall not increase their generating plant beyond that which their generating station as now constructed is capable of accommodating.

4. The Council shall not be required to guarantee to take any fixed amount of energy from the company.

5. Provides for a supply being given by the company within 18 months from the passing of the Act.

6. Says that if within 12 months the company cannot prove that they will be ready to supply, the special provisions of the Act as regards Stepney shall cease to have effect.

7. The said supply of energy shall be delivered by the company at such points within the said borough as the Council may require, provided that the number of points shall not exceed two until the extent of the demand from each point reaches 2,000 kw., after which the Council may increase the number of points by one for every additional 2,000 kw., or fraction of 2,000 kw., which the Council may demand from the company, provided, nevertheless, that the company may vary the location of the point of supply to any other point within the radius of a circle described from the point required by the Council, such circle having a diameter of three furlongs.

8. The said supply shall be delivered converted to the form and transformed to the pressure reasonably required by the Council.

9. Provides that in the event of a breakdown or failure of supply by the company the Council may make temporary arrangements for supply at the company's expense.

10. Puts damages for failure of supply on to the company.

11. The charge to be made by the company in respect of bulk supply shall not at any time exceed a fixed sum of £3 per annum per kilowatt of the maximum demand and a running charge of ·33d. per unit, and the Council shall have the right at the expiration of every period of five years from the passing of this Act to appeal to an arbitrator to be appointed by the Board of Trade for a reduction of the above-mentioned running

Digitized by Google

charge, such arbitrator to have regard to the company's actual cost per maximum kilowatt demanded on all their stations and their production cost per unit.

12. The price charged by the Council to power consumers shall not exceed by more than £1. 10s. per annum per kilowatt demanded the price charged by the company for the bulk supply.

13. The Council shall lay down such additional distributing mains as may reasonably be required to deal with the increase or extension of business. In the event of the Council making default therein to such an extent that another company is allowed by Parliament to supply in Stepney, the company shall themselves be entitled to lay such new mains as the extension of business and competition with the new company may require.

The remaining five sub-sections deal with the purchase of a sub-station site, of certain three-phase cables, and to the settlement of disputes by arbitration.

Clause 85*d* deals with the Bexley Urban District Council, whose generating station is to be taken over. The purchase is to take place within two years from March 31, 1906, on the following terms:

2. The company shall as consideration for and subsequent to the taking over of the said generating station pay to the Council from time to time as and when payments fall due from the Council sums equal to the sums payable by the Council for interest, repayment of instalments, and charges on or in respect of the loans raised by the Council on account of the capital expenditure on the said generating station as hereinbefore defined, but subject to any necessary apportionment to be made, provided that in ascertaining the amount of the sums aforesaid no part of any revenue of the Council shall be taken into account in relief of the company. Provided also that the company may at any time at their option, and if the lenders or any one or more of them agree to receive back the loans earlier than the Council are entitled to repay the same, pay to the Council the amount required by such lenders to pay off the loans in lieu of continuing to pay future interest instalments and charges thereon. All stores not paid for out of capital shall be taken over by the company at a valuation.

3. The company shall supply and the Council shall take all current required for the electrical undertaking and tramways of the Council at a flat rate which shall not exceed 1·35d. per unit, provided that if the company call upon them to do so the Council shall supply all power users in the Council's area with current at a lower rate than the above, on condition that the company compensate the Council for any loss resulting from such supply, including loss of profit to the Council, such loss of profit to be agreed between the respective engineers of the Council and the company, or, failing agreement, to be determined by an umpire to be appointed by such engineers. Such umpire shall have regard to the whole circumstances of the case, and his decision shall be final.

Sub-sections Nos. 4 and 5 provide for the working of the switchboard and the control of public lighting, and the revision by the Board of Trade of the prices charged every five years.

6. Fixes the points at where the current shall be metered both for the tramways and general supply.

7. The current shall be supplied at the pressures and on the systems and with such regularity as may be reasonably required by the Council.

8. The company may at any time after the passing of this Act, and after the erection of a permanent generating station of their own and the connection therewith of the Council's cable system, so as to give a satisfactory supply of current discontinue the use of the said generating station taken over from the Council and dispose of the same and the plant and machinery therein, provided that the company shall not effect such disposals until they have given to the Council a satisfactory guarantee for the repayment of the said outstanding loans and interest thereon.

9. The company may use for the supply to other districts the existing generating station and plant taken over from the Council, provided that such use shall in no way interfere with the efficiency or the reliability of the supply given to the Council.

10. The company shall be at liberty to sell current direct otherwise than through the Council's mains to all power and traction users, but the company shall not otherwise compete with the Council.

Sub-section 11 fixes the expiration of the bulk supply to the Council in 42 years, subject to one year's notice and to compensation for the unredeemed portion of special plant and mains installed in Bexley within 25 years of that time.

12. Binds the Council to take their public lighting and tramway supply from the company, and to insert a similar clause in any lease of the tramways.

The usual arbitration and other clauses as to failure of supply follow.

The Barking Urban District Council's agreement is somewhat similar to the above, but it covers the purchase of the complete undertaking by taking over the present loans and paying also the loss from working. The following clauses are of special interest:

6. The average prices to be charged by the company for electrical energy within the Council's area shall not exceed the following:

Energy for power purposes	1d.	per unit.
,, traction purposes.....	1d.	,,
,, public lighting	1·5d.	,,
,, private lighting	4d.	,,

14. The company shall supply the Council with energy for the whole of their existing and any future sewage pumping system at an average price not exceeding ¾d. per unit.

16. The company shall either take over the staff which the Council now employ in their electrical undertaking at the date of the transfer thereof or, at the option of the company, shall compensate any member of the said staff for loss of office. All increase of salaries and wages made by the Council after the passing of the said Bill into law shall be subject to the reasonable approval of the company.

The agreement with the Kent Electric Power Company is to ensure mutual co-operation. This is shown by the clauses which follow:

2. The London Company are to give to the Kent Company and the Kent Company are to take from the London Company all energy required for supply to the customers of either company within or for use or distribution within the common area and the control and management of the distribution of energy therein shall, subject to the terms of this agreement, be in the hands of the Kent Company.

3. All energy to be supplied by the London Company in the common area shall be distributed by the Kent Company upon the terms of this agreement.

4. The London Company shall not erect or operate or be interested in a generating station in the area of the Kent Company outside the common area. No main feeders or distributing apparatus shall be laid or erected by the London Company in the area of the Kent Company without the consent of the Kent Company.

6. The Kent Company shall pay to the London Company for all energy so supplied by the London Company to the Kent Company the gross amount received by the Kent Company for the current distributed by them to the customers less the following deductions: (*a*) A sum equal to 10 per cent. per annum upon the capital cost to the Kent Company of all mains, feeders, and distributing apparatus in the common area, which amount of 10 per cent. is intended to cover 3 per cent. for depreciation and 7 per cent. for interest on capital. In the event of the said 3 per cent. proving insufficient or excessive for the purpose, the amount shall be subject to revision from time to time between the parties. (*b*) The amount of the actual cost to the Kent Company of all their working expenses and all annual payments attributable to revenue account in the common area. (*c*) A fair proportion of the administrative expenses of the Kent Company attributable to the common area. Any differences under this clause shall be referred to arbitration. The steps to be taken for the development of business and the price or prices of supply in the common area are to be settled from time to time between the parties by agreement in consultation, and in case of dispute are to be stttled by arbitration.

9. The London Company shall not supply energy within the common area for use without such area within the county of Kent.

On Tuesday the cross-examination of Mr. Merz was continued in the morning, but was subsequently interrupted to allow two other witnesses to be heard. One of these was the Hon. C. PARSONS, who repeated the evidence given before the House of Lords Committee as to the possibility and advantages of having very large generating units. The cost per horse-power of electrical machinery decreased as the size of the turbines increased, and the larger the generating station the more cheaply it could be equipped. London was so great that if its equipment were appropriate it could be supplied with electricity at a cheaper rate than was possible in any other city in the world. At present all its electric generating stations combined did not possess machinery as powerful as that of the two latest Cunard steamships, which had turbine-engines capable together of producing 140,000 h.p.

Mr. C. E. L. BROWN gave similar evidence, and also

Digitized by Google

figures showing that large steam-turbines were finding favour on the Continent.

On Tuesday night in the House of Commons Mr. BONAR LAW, in answer to a question, said the Bill as at present drawn provides that no agreement for the sale of an undertaking shall be of force until it had received the approval of the Board of Trade, but until the Bill had received Royal assent no case can be submitted to or considered by the Board of Trade. Thus the agreements, which we abstract above, have yet to be considered by the Board of Trade should the Bill pass.

In reply to Mr. Lough, Mr. BALFOUR said he understood this measure was not uncontroversial, and, if so, there was little hope of its passing this session.

On Wednesday the cross-examination of Mr. Merz was again continued on lines similar to that followed before the House of Lords Committee. Evidence was then given by representatives of the Great Northern and Great Eastern Railway Companies in favour of the Bill.

Mr. BALFOUR BROWNE, K.C., for the County of London Electric Supply Company, informed the committee that a bargain had been arrived at between the two companies. The arrangement, which he claimed to be in the interest of the companies and public alike, was that when the promoters of the Bill had got their system into proper working order, three years being allowed for the purpose, the County of London Company agreed to take from them current for any additional requirements beyond that which could be met by their present plant, upon arbitration terms (failing agreement), on the basis of a substantial reduction below what it cost the County of London Company to manufacture electricity. They undertook to adopt the same price as that in the Administrative Company's schedule throughout the industrial area, so that the consumer would at once get the benefit of cheap power.

Mr. FITZGERALD, K.C., confirmed this statement, and submitted a clause for carrying out the agreement, which is not unlike that for the Stepney supply as regards general conditions.

PERSONAL.

Mr. F. Schofield, traffic superintendent of the Bradford city tramways, has been appointed general manager of the Leyton tramways at a salary of £300 a year.

The Poplar Borough Council have appointed Mr. W. Innes, St. Andrew's Cross Electricity Works, Glasgow, assistant electrical engineer, at a salary of £200 per annum, rising by annual increments of £10 to a maximum of £300 a year.

The Brighton Corporation Tramways Committee recommend that Mr. William Marsh be appointed tramways engineer and manager at a salary of £300 per annum, increasing by annual increments of £50 to a maximum of £400.

We regret to learn that Mr. W. A. Thompson, assistant mains superintendent to the Tynemouth Corporation, lost his life at Tynemouth on the 14th inst. while assisting another bather who had been caught by the current, and before it was possible to get a boat out both were drowned. Mr. Thompson was a hard-working and promising man who was greatly esteemed by all in the works.

The King's Lynn Town Council have increased the salary of their electrical engineer from £200 to £220, with a further increase of £10 at the end of each following period of 12 months until a maximum of £250 is reached.

Mr. J. B. Hamilton, general manager of the Leeds tramways, has been elected president of the Municipal Tramways Association.

TRADE NOTICES AND NOVELTIES.

Controllers.

Messrs. Dick, Kerr, and Co., Limited, London, have recently issued an illustrated pamphlet descriptive of their metallic shield blow-out controller for electric tramways, railways, cranes, etc. In regard to the evolution of the solenoid blow-out, which constitutes such an important part of this controller, each development has been the result, we are told, of careful observation under widely varying conditions. The chief improvement arises in the method of protecting the solenoid. As shown in Fig. 1 herewith, present practice is to place it in a metallic shield. The coil is enclosed in a casing of copper or other non-magnetic material, and it can be then brought directly into the sweep of the arc. The external magnetic field created round the shield of non-magnetic metal attracts the arc to the shield and divides it in two, one arc going from the contact finger to the shield and the other from the shield to the contact segment. These two arcs travel rapidly in opposite directions on the copper shield, and finally become united again in the air, but around the coil and shield; the arc at this stage has become attenuated to such an extent as to rupture, and may be, in fact, ruptured long before it has actually encircled the blow-out device. In Fig. 2 is shown the action of the arc. At A the arc is

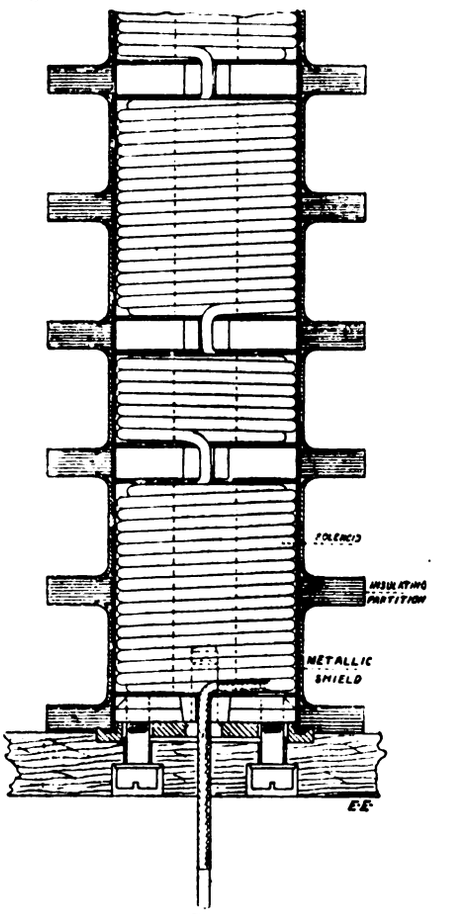

FIG. 1.

just started between the electrodes, and a deflection of the arc towards the shield is visible. At B the arc has struck the shield, and is commencing to encircle the section; at C the shield is partially enclosed; and at D the arc has united in the air and has left the shield.

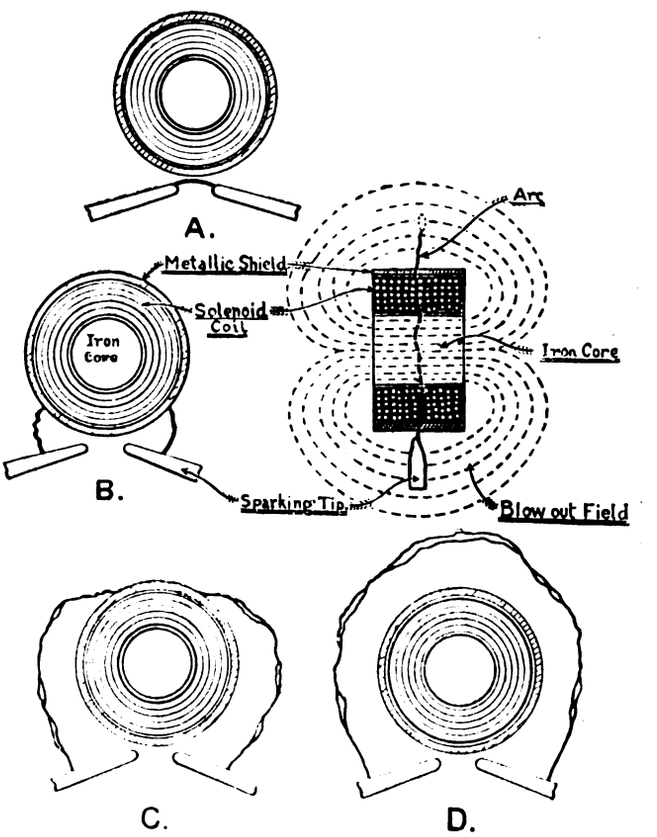

FIG. 2.

Generally speaking, the arc is literally swept over the shield with great rapidity, and does not affect the metal in the slightest degree. It is interesting to note the tendency of the arc to travel on the centre of the copper shield, and this is of great advantage, as the

Digitized by Google

insulating partitions are not subject to injury. That the copper ring suffers to no extent from the discharge may be gathered from the fact that on examination after two years' continual use no material depreciation could be detected either on the metal ring or on the partitions. The blow-out is hinged on the pivots, and can be swung back and lifted out for inspection and cleaning. In swinging it back the trolley connection is broken, and, therefore, the current can be applied only when the blow-out is closed. It has been demonstrated on an ordinary service controller that 60 or more amperes on an inductive load may be broken time after time by slowly separating the finger and contact by barely $\frac{1}{16}$in. without the slightest trouble. Other novel features are combined in the controller, but for particulars of these we must refer the reader to the pamphlet under review.

MANCHESTER ELECTRICITY ACCOUNTS.

The accounts of the Manchester Corporation electricity department for the year ended March 31, 1905, show a total expenditure on capital account to that date of £2,199,689. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc, are given below.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
To generation of electricity	70,197	10	2
Distribution of electricity	35 504	18	9
Rents, rates, and taxes	19,910	16	8
Management expenses, salaries, etc.	8,311	7	2
Law and parliamentary charges	225	9	9
Special charges, insurances, etc.	1,483	18	6
Amount written off for bad debts	358	1	1
Special renewals	13,327	17	4
Renewals suspense account	25,000	0	0
Balance carried to net revenue account	127,379	16	6
	£302,199	15	11

Cr. Income.	£	s.	d.
By sale of current by meter	300,150	1	9
Public lighting	675	5	4
Rental of meters	383	1	8
Rental of motors	942	1	10
Cottage rental, less repairs, etc.	49	5	4

LEGAL INTELLIGENCE.

MIDWOOD AND CO. v. MANCHESTER CORPORATION.

On the 13th inst. the Court of Appeal dismissed this case, in which the defendants appealed against a verdict and judgment for the plaintiffs for £677 for damage to stock arising from a fire caused by the fusing of one of the Corporation's electric mains. The action was tried by Mr. Justice Lawrence and a special jury.

Their Lordships came to the conclusion that the leakage in the mains causing the explosion was clearly a nuisance, and there was nothing in the Electric Lighting Acts which authorised a leakage of that kind. They also held that there was ample evidence of negligence on the part of the defendants to go to the jury, and therefore dismissed the appeal with costs.

BIDEFORD AND WESTWARD HO! LIGHT RAILWAY.

On the 11th inst. Mr. Justice Walton resumed the hearing of the case of the British Electric Traction Co. and the Bideford, Westward Ho! and Appledore Railway Co. *v.* Charles Chadwell, contractor, of Blackburn. The claim was for money expended by plaintiffs in completing certain works undertaken. Plaintiffs alleged that it was agreed that in the event of defendant wilfully making default in proceeding with the execution of the works, which consisted of certain electric tramway construction, plaintiffs might complete them and recover any extra expense which they might incur. Plaintiffs claimed £12,000, but that was reduced to £8,690, after allowances had been made to defendant as to the value of materials left by him on the ground, and fees due to him as engineer in the construction of another tramway at Devonport, etc.

Mr. A. S. CHAPMAN, formerly engineer in Mr. Chadwell's employ on the Bideford tramway contract until the plaintiffs took it over, called on behalf of the defendant, said for a time he remained on the job, and had with him a cashier, leading carpenter, and several men. If necessary he could have got more men and carried the work on, instead of things being allowed to stand still for a long time. One of the lines was nearly completed; had he been allowed he could have finished it within a fortnight. The value of the plant and materials on the works at the time was nearly £3,900, and all that ought to have been allowed to defendant by the plaintiffs. He was ordered to stop the work by the engineer of the company, by the town clerk, and by Mr. Chadwell.

Mr. ASHTON, for defendant, submitted that the fact of stopping the work, pending an amicable arrangement with the authorities, did not constitute wilful default, and, therefore, defendant ought to succeed in this action and receive damages.

Mr. LLEWELLYN DAVIS, for the company, stated that the delay was not the fault of plaintiffs, but was caused through the friction between the defendant and the authorities.

Judgment was entered for plaintiffs for £7,500, with costs.

ATTORNEY-GENERAL v. MANCHESTER CORPORATION.

On Saturday, in the Chancery Division of the High Court, Mr. Justice Swinfen Eady heard a summons in an action brought by the Attorney-General at the relation of Sutton and Co., carriers, of Manchester, to restrain the Corporation carrying on business in alleged opposition to them, and from applying the funds of the Corporation for that purpose. The summons asked for an affidavit of documents and for leave to deliver to the defendants some very lengthy interrogatories. The defendants objected to Sutton's as trade rivals looking at their books. The statement of claim sets out that the Corporation are not entitled to use the city rate for the purpose of an undertaking for carrying parcels, and that they are burdening the tramway to an extent they are not entitled to by applying the revenue to other purposes.

It was arranged that the plaintiffs should prepare a notice to admit facts as speedily as possible, and the summons should stand over generally, but to be mentioned again some time during the present month.

WAKEFIELD, LEEDS, AND DEWSBURY LIGHT RAILWAY.

On Thursday week Mr. Justice Swinfen Eady, in the Chancery Division of the High Court, heard an application on behalf of the Electric Construction and Maintenance Company, and now under liquidation, against their solicitors, Messrs. Harrison, Beaumont, and Smith, for an order that they should deliver bills of costs and of their work done for the company, and also for an order that those bills should be taxed.

His Lordship held that it would be oppressive to order the solicitors to deliver bills of costs nearly two years after the company had gone into liquidation, and dismissed the summons, with costs.

POST OFFICE TELEPHONE RENTS.

In the Peterhead Small Debt Court on Friday Lord Stanley, the Postmaster-General, sued three subscribers to the Post Office telephone service for payment of £4. 10s. each, the annual subscription for telephone exchange line from their premises to the post office at Peterhead, with right of communication, in terms of agreement entered into in 1903, and fees for transmission of messages for one year. The defendants each lodged a counter-claim of £10 for loss and damage through default or failure of the telephone service to implement the agreement.

After hearing a mass of evidence, which took three hours, the SHERIFF said they had the statement of one man against a whole host of witnesses for the defence. He must prefer the evidence of the host, and he found in each case for the defendants, assessing a counter-claim at £4. 10s. (the sum claimed by plaintiff), and costs.

COMPANIES' MEETINGS AND REPORTS.

METROPOLITAN DISTRICT RAILWAY.

An extraordinary general meeting of the shareholders was held on Monday last for the purpose of authorising the Company to raise £75,000 by the creation and issue of second preference stock at 5 per cent., a sum of £300,000 by second preference stock of additional capital authorised by the Metropolitan Railway Act of 1897, and a sum of £100,000 by debenture stock at 4 per cent. under the Metropolitan Railway Act of 1905. Mr. R. W. Perks, M.P., presided, and the statutory resolutions were carried.

The CHAIRMAN said the directors had agreed to sell the whole of this issue at a price of 65, that being the same price as the second preference stock of the Company. They had concluded a satisfactory arrangement with the Brompton and Piccadilly Company for running over a portion of the wider line. The total expenditure up to the present moment on the electrification of their railway had been £1,373,766, and further expenditure would bring that sum up to £1 623,766. Except £515,000, the amount provided by debenture stock, the whole of the money had been raised by ordinary and preference stock. In reply to a shareholder who wanted to know when the directors expected their line fully electrified, he said they hoped to be putting forward and maintaining a different service in a few weeks.

ELECTRIC CONSTRUCTION.

Mr. J. W. Barclay presided over the ordinary meeting on July 14. Particulars of the report appeared in our issue of July 7, and it was adopted.

The CHAIRMAN said that the profit was only sufficient to justify payment of the dividend on the preference shares, but they carried forward £3,319. The Electric Power Storage Company, in which the Company had a large interest, continued to do very well in spite of the general depression, and its previous dividend of 6 per cent. had been maintained. The directors, while satisfied with the investment, were, however, of opinion that part of the funds invested in this accumulator business might be more advantageously employed in their own, and probably part of their holding in that company would be offered to the shareholders within the next few months. The general expenses had been reduced by £870. During last year competition had been intensified, and prices further reduced, not by their former German and American competitors, but by the great extension of factories for making electrical plant in this country, where the capacity for producing electrical plant had doubled in the last few years. The accounts showed that the Company were in a stronger financial position than ever before. They got a fair share of what orders were going, and the results of the business in the past year were not worse than the experience of others similarly situated.

ELECTRICAL POWER STORAGE.

Mr. J. IRVING COURTENAY, who presided on July 14 at the annual meeting, in moving the adoption of the report (published in our issue of July 7), said that during the year the Company, in addition to the smaller class of business, had obtained a full share of the large central-station contracts throughout the country, and had completed 16 central-station batteries, six of which were in the metropolitan area. The Company's works were fully employed, and had work in hand for several months ahead, though there were signs that the business in accumulators was not so brisk as it was 12 months ago, in addition to which the cutting of prices, which had now become general, rendered it possible to make only the smallest profit on each individual transaction.

A dividend at the rate of 6 per cent. on the ordinary shares was adopted.

DIRECT UNITED STATES CABLE.

The report for the six months ended June 30, 1905, shows an increase of £6,348 in the revenue, which totalled £48,469. The expenses, including provision for pension fund, endowment assurance, and income tax, but exclusive of cost of cable maintenance, amounted to £22,571, leaving a balance of £26,897 as the net profit, making, with £2,876 brought forward from the previous half-year, a total of £29,774. Three quarterly interim dividends of 3s. each per share, amounting to £27,319, have been declared and paid during the financial year, and a final dividend of 3s. per share is now proposed, together with a bonus of 1s. per share, making, with three interim dividends, 3¼ per cent. for the year, being a total distribution of £39,461. The reserve fund has been debited with £3,946 for cost of cable maintenance, and after being credited with interest on investments, profit on sale of securities, and amount transferred from revenue, the balance now amounts to £482,947, taking the investments at cost price.

GERMAN-DUTCH TELEGRAPH.

The report of the first year's working states that a joint subsidy of £95,000 per annum has been granted to the Company for 20 years. Of this amount £76,250 is payable by the German Government and £18,750 by the Dutch Government; 90 per cent. of the cable receipts will be reckoned towards the subsidy during the 20 years. The Company is now laying submarine cables from Menado in the Celebes *via*

Digitized by Google

Jap in the Carolines to the United States island of Guam, where a connection is being formed with the American-Pacific cable; and from Jap to Shanghai, where a junction will be effected with the German cables between Shanghai, Tsingtau, and Chifu, and thence with the network of the Great Northern Telegraph Co., whose lines run over Siberia to Europe. Forty years' cable-laying rights have been granted for Jap and Menado, while similar privileges have been secured from the Chinese Government for Shanghai and from the United States Government for Guam, where the Commercial Pacific Cable Co. will work the cables by virtue of an agreement with the German-Dutch Co. An agreement has been concluded with the Great Northern Telegraph Co. to maintain and repair the cables during the first 10 years' working for a fixed amount.

THOMAS PARKER, LIMITED.

In their report for the past year the directors regret to have to report that the severe competition and reduced prices, combined with trade depression, still continue in the electrical industry. After deducting general charges, maintenance, and interest on debentures, the accounts show an adverse balance, which it is proposed to meet by transferring £6,000 from the reserve fund, carrying forward £153. 19s. 1d. to next year's account. The directors have thought it advisable to transfer £1,500 from the reserve fund to a suspense account to meet a possible loss that may be made in connection with foreign agencies. The buildings and plant have been well maintained, and in view of the large amount written off for depreciation in former years and the sums spent out of revenue for maintenance of plant and machinery, the directors have not considered it necessary to draw on the reserve fund for the depreciation account, as the average over the 11 years during which the Company has been working is well above the usual figures for similar manufacturing companies. The directors have decided to forego one half of their fees for the year. The directors attribute the unsatisfactory results entirely to lack of orders during the year, as although the works were full at the beginning of the year's working it became advisable later to stop all night work and reduce the number of hands employed and eventually to resort to short time rather than attempt to keep the works full of orders at prices which would not pay the cost of production. During the last few months it is satisfactory to note that the works are again working full time. The works staff has been kept in a fully efficient state, and the directors are satisfied that no opportunities have been lost to secure work at remunerative prices, or to improve designs and reduce cost of production to meet the adverse conditions.

GENERAL ELECTRIC.

The report of the directors for the year ended March 31, 1905, states that the net trading profits and income from investments, etc., amount to £73,822. 16s. 9d.; after deducting depreciation and debenture interest amounting to £25,919. 15s. 11d., there remains a balance of £47,903. 2s. 10d., out of which the dividend on the preference shares at the rate of 5 per cent. for the year ended March 31, 1905, has been paid, absorbing £12,500, leaving an available balance of £35,403. 2s. 10d., which the directors recommend should be appropriated as follows: payment of managing directors' and employés' bonus, £3,540. 6s. 6d.; payment of dividend on ordinary shares at the rate of 5 per cent. for the year ended March 31, 1905, £15,875; reserve account, £15,987. 16s. 4d. The reserve account stands in the accounts at £80,255. 7s. 2d., being the amount of undivided profits as at March 31, 1904; the proposed appropriation of the undivided profit of the year ended March 31, 1905, amounts to £15,987. 16s. 4d; giving a total of reserve account of £96,253. 3s. 6d. The trading profits have suffered under the continued depression of trade. The Witton engineering shops and foundry have been fully occupied during the last 12 months, and the results have been satisfactory. The carbon works have throughout the year been working at their full capacity, and produced a uniformly high standard of quality. The directors hope that the unprecedented cutting of prices by foreign competitors may soon end, and allow the Company to reap the commercial benefit of this important enterprise. The Manchester, Birmingham, and London factories continue in their normal progress. During the year further 1,570 ordinary shares have been allotted to the directors of the Company and members of the staff at par.

CROMPTON AND CO.

The report of the directors for the year ended March 31 last states that, although the volume of business done by the Company is as large as in previous years, prices still rule very low. The results of the contracts carried out by the Company during the year have proved satisfactory, but the profits realised in this direction have been adversely affected by the low prices obtained for goods manufactured at the works. With a view to greater economy in the future, the directors have entirely reorganised the staff at Chelmsford. The net profits for the year amount to £9,128. 10s. 7d., which compares unfavourably with the profit of £14 584. 5s. 4d. in the preceding year. After providing debenture interest and other items, there remains with the sum brought forward from last year, a balance of £2,713. 2s. 1d. Considering that in prosperous years, instead of distributing large dividends, the directors placed substantial sums to a reserve fund, they are of opinion that the present occasion is one which justifies the application of part of such undivided profits to assist in paying a dividend. They therefore propose to take £4,000 from the reserve fund, to pay a dividend at the rate of 2½ per cent. per annum for the year, and to carry forward a balance of £656. The loans and other advances owing to the Company by the Chelmsford Electric Lighting Co. have been repaid by the Electric Supply Corporation, partly by debentures, and the costs of realising the debentures, as well as a small discount on the shares held in the new company, have been charged to the contingency fund. The balance of the contingency fund, £2,058. 12s., has been added to the provision for doubtful debts. Important contracts for constructing and equipping electric lighting and tramway undertakings, both in the United Kingdom and abroad, have been secured on terms which should undoubtedly result in satisfactory profits for the current year, so that the prospects of the Company for the future are more encouraging. Amongst others, large contracts have been secured from the Electric Supply Corporation, and in order to assist in obtaining capital for that company it has been considered advisable to guarantee its earnings for four years, and for this purpose an investment in the shares of a guaranteeing company has been made. An insurance has been effected to cover part of this risk. Should any money be paid under the guarantee, it has to be returned out of future profits of the Electric Supply Corporation, with interest.

ELECTRIC SUPPLY CORPORATION.

The report of the directors for the year ended Dec. 31, 1904, states that the negotiations referred to in the last report were duly completed, and as a result the capital was increased by an issue of 11,092 shares. The Company has acquired at par the whole of the share capital of the Chelmsford Electric Lighting Co. by an issue of 7,000 fully-paid shares in this Company. The Chelmsford undertaking is a prosperous one, the net profits of that undertaking for last year amounting to £3,869. By the issue of the above 7,000 shares the total share capital alloted to Dec. 31, 1904, was 21,492 shares of £5 each. The directors have made an issue of £50,000 of 4½ per cent. debenture stock, which amount has been secured by a deed of trust. Since Dec. 31 last the stations at Exmouth and St. Andrews have been erected and equipped, the mains have been laid, and the supply has commenced. The Company has, therefore, the following stations at work: Dalkeith, Chelmsford, Dollar, Totnes, Jedburgh, Exmouth, Melrose, St. Andrews. The capital expenditure during the year, as set out under the headings of the several towns in the capital account, has amounted to £43,677. 6s. 8d. In order to carry out the operations of the Company as described in the original prospectus, further capital was required, and since the closing of the accounts for 1904 negotiations have been brought to a successful issue for the placing of an additional 20,000 shares. In consequence, the undertakings at Hendon, Hitchin, Falmouth, and Dumbarton (in the latter case including the tramways) are being pushed forward as quickly as possible. Owing chiefly to the dividend on the Chelmsford undertaking, a small balance, £216, has been carried forward.

LISBON ELECTRIC TRAMWAYS.

The report for the year 1904 shows a net available balance of £42,730 after deducting interest and amortisation due on the debentures of "Companhia Carris de Ferro de Lisboa," and after payment of debenture interest and other charges, together with London office expenses and directors' remuneration, and providing reserve for depreciation, insurance reserve account, and exchange reserve account. The usual preference dividend of 6 per cent. for the year 1904, amounting to £25,533, has been paid, leaving £17,197 to be carried forward.

NEW COMPANIES REGISTERED.

Portable Accumulators, Limited.—Capital, £25,000. Object: to acquire the business and the sole right of manufacture and sale in the United Kingdom of electrical portable accumulators, which heretofore formed part of the business carried on at various addresses by the Tudor Accumulator Co. Registered office: King Edward's Mansions, 210, Shaftesbury-avenue, W.C.

Auto Claw Co., Limited.—Capital, £15,000. Object: to carry on the business of electricians, electrical engineers, etc. Registered office: 38, Beech-street, Barbican, E.C.

James C. Kay and Co., Limited.—Capital, £10,000. Objects: to acquire the business carried on at the Phœnix Foundry, Brook-street, Bury, as James C. Kay and Co., and to carry on the business of iron and brass founders, engineers, electrical engineers, etc. Registered office: Phœnix Foundry, Heap Bridge, Bury.

Liens Registered.

London United Tramways (1901), Limited.—Acknowledgments of indebtedness, dated June 13, 1905, registered June 23, creating £258,000 and £42,000 further debenture stock, making a total of £1,331,000, and being supplemental to a trust deed dated Feb. 26, 1902, and indenture of acknowledgement of indebtedness dated July 22, 1903, for securing £1,031,000. Trustees: Lord Revelstoke and Sir George White, Bart. Charged on various freehold and leasehold properties, the undertakings, and all property, including the unpaid capital, whether called or not.

Telegraph Printing Co., Limited, Manchester. — £950 debenture, dated July 6, 1905, charged on the company's undertaking and property, present and future, including uncalled capital, have been registered. No trustees.

Phillips's Commutator Grinder Co., Limited, London E.C.—Lien registered July 11, for £50 5 per cent. debentures, part of £5,000. Amount previously issued, £600. No trustees. Charged on all the property, present and future, including the uncalled capital.

Oriental Telephone and Electric Co., Limited.—A trust deed, dated June 28, 1905, to secure £100,000 debenture stock, has been

Digitized by Google

registered. Property charged: the company's undertaking and property, present and future. Trustees: Sir Auckland Colvin, Earl Soham, Framlingham, Suffolk; and G. F. Braithwaite, Kendal, Westmoreland.

Amazon Telegraph Co., Limited.—A Board resolution under seal, dated June 20, 1905, creating £35,900 further debentures, has been registered. Property charged: A subvention of £17,125 per annum and all other moneys payable by the Government of Brazil under Clause 10 of a concession dated April 29, 1895. Trustees under deed mentioned below; Sir William C. Quilter, Bart., King's Arms-yard, E.C., and Sir John D. Pender, K.C.M.G., Electra House, Finsbury-pavement, E.C. The present issue ranks *pari passu* with £119,700 like debentures issued in 1897. Both issues are covered by a trust deed dated Aug. 5, 1897. The company reserves power to issue further debentures ranking *pari passu* with the above to the extent of £39,100. The whole of the above debentures rank after £150,000 6 per cent. debentures created in 1901. A trust deed, dated July 11, 1905 (supplemental to said trust deed of 1897), securing £75,000 debentures, created by resolution of June 20, 1905 (consisting of the £35,900 and £39,100 above mentioned), has also been registered. Property charged and trustees, as above.

FORTHCOMING EVENTS.

TUESDAY, JULY 25.

Junior Institution of Engineers.—At 6.30 p.m., visit to the New Vauxhall Bridge Works.

Permanent-Way Institution. — Summer convention begins on July 21, continuing till July 27, in the course of which a visit will be paid to Holland.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Florianopolis (Brazil).—The Municipality require tenders for the lighting of the town by Oct. 2.

Turnu-Severin (Roumania).—The Mayor invites tenders for the electric lighting of the town. Tenders by Sept. 10.

West Ham.—The Council invite tenders for the erection of tramway offices and car depot, Greengate-street, Plaistow. Tenders by July 25.

Beckenham.—The Urban District Council invite tenders for (Section A) water-tube boilers; (B) steam alternator. Tenders by 22nd inst.

South Shields.—The Town Council invite tenders for the laying of the permanent way for the service line to the car-shed in Dean-road. Tenders by 22nd inst.

Olympia 1905 Exhibition.—The Executive Committee invite tenders for the loan or hire of 300-kw. direct-coupled steam set. See advertisement in last issue.

Brussels.—The Government Telegraph Department require tenders for 14,700 pine telegraph poles. Specification 76 may be obtained from their office at Brussels. Tenders by Aug. 9.

Alicante (Spain).—The Harbour Board (Junta des Obras del Puerto) require tenders for two electric cranes, capable of lifting 10 000 ko. and 1,500 ko. respectively. Tenders by Sept. 15. Estimate, 107,010·10 pesetas.

Calanas (Spain).—The Municipality require tenders for the installation and working for 10 years from Jan. 1, 1906, of the electric lighting of the town. Tenders by July 27 to the Alcalde of Calanas, province of Huelva, Spain.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

Merthyr Tydfil.—Tenders are invited by the Urban District Council for the erection of refuse destructor plant capable of effectually burning 120 tons of refuse per day, together with all buildings and contingent works connected therewith. Tenders by Sept. 1.

London, S.W.—The London County Council invites tenders for the manufacture, supply, and delivery of (*a*) one five-ton overhead electrically-driven travelling crane and (*b*) one 2½-ton overhead electrically-driven travelling crane. Tenders by 10 a.m. on July 25.

London, S.W.—The London County Council invites tenders for the manufacture, supply, and delivery, separately, of (*a*) double-deck car bodies with roof covers; (*b*) maximum traction swing bolster trucks for electrical cars; (*c*) complete electrical equipments for cars. Tenders by 10 a.m. on July 25.

Worthing.—The Corporation invite tenders for (1) supply and erection of one dry-back marine type steam-boiler with fittings; (2) supply and erection of steam feed, drain, and other piping; (3) supply of vulcanised bitumen-sheathed feeder and pilot cables; (4) supply of stoneware conduits. Tenders by 12 noon on 24th inst.

Ebbw Vale (Mon.).—Tenders are invited for the following, for the Ebbw Vale Urban District Council: (Section A) cables; (B) overhead lines; (C) street lamps and fittings; (D) meters. Specifications, etc., may be obtained at the offices of the consulting engineer, Mr. Reginald P. Wilson, 66, Victoria-street, Westminster. Tenders to the Clerk of the Ebbw Vale Urban District Council by 12 noon on Aug. 5.

Dublin.—Tenders are invited for the supply of three electric locomotives for haulage of refuse wagons on the city tramways; nearly 1,000 yards run of street tram tracks and electricity mains, overhead trolley wires, with street posts and connections; two electric and one steam capstan, etc. Specification, etc., may be inspected at the office of the city engineer, Mr. Spencer Harty, City Hall, Dublin. Tenders to the Chairman, Cleansing Committee, 3, Cork-hill, Dublin, by 12 noon on July 25.

Erdington.—Tenders are required for the construction of Section No. 1 of the Erdington tramways, comprising the laying of the permanent way, including copper bonding, wood block paving, and other works incidental to the laying of about 2½ miles of double-track tramway, for the Tramway Committee. Tenders to the joint engineers, Mr. Robert Green (of Messrs. Pritchard, Green, and Co.), of 37, Waterloo-street, Birmingham, and Mr. Herbert H. Humphries, engineer to the Council, Public Hall, Erdington.

Municipal Board of Mussoorie (India).—The Municipal Board invite tenders for the supply, delivery, and erection at sites, in complete working order, of the following plant: (*a*) steel power pipes; (*b*) water-motors; (*c*) alternators with exciters; (*d*) switchboards with instruments and apparatus; (*e*) transformers; (*f*) induction motors; (*g*) pumps; (*h*) workshop machines. Also for the supply and delivery of the following: (*a*) bare copper wire for overhead mains; (*b*) insulators and lightning arresters; (*c*) arc and incandescent lamps; (*d*) telephone equipment; (*e*) workshop tools; (*f*) general stores. Specifications, form of tender, and general conditions can be obtained on application to Mr. C. H. Shanan, municipal electrical engineer, Municipal Office, Mussoorie, India (telegraphic address, Shanan, Mussoorie), on payment of a deposit of Rs.75 (£5), which amount will be returned on receipt of a bona fide tender. Tenders by Oct. 23. See advertisement.

RESULTS OF TENDERS.

Loughborough.—The tender of Gent and Hurley, Leicester, at £386. 14s. 7d., has been accepted for an installation of telephonic communication between the various departments and works of the Corporation.

London County Council.—The tender of Mountain and Gibson, Bury, amounting to £2 360, has been accepted for four electrically-driven watering cars, with Westinghouse equipments similar to those fitted on the Council's electric tramcars.

King's Lynn.—The Town Council have accepted the following tenders for the electricity works: A. Dodman and Co., six fuse boxes at £3. 3s. 6d. each, six surface covers at £1. 15s. 9d. each; Pattrick and Thompsons, creosoted boards required for laying over the new cables, £6. 3s. 9d.; C. Copley, Limited, slack coal, 8s. per ton in summer and 8s. 6d. in winter.

Barrasford Sanatorium.—Messrs. Falconer, Cross, and Co., 4, St. Nicholas-buildings, Newcastle-on-Tyne, report an order for the complete installation of electric light and bells at the Barrasford Sanatorium, Northumberland, which is being built for the Newcastle-on-Tyne and Northumberland Branch of the National Association for the Prevention of Consumption, the work being carried out in accordance with a specification by Shepherd and Watney, of Leeds.

Ossett.—The Corporation have provisionally accepted the following tenders for the electricity works on condition that the Local Government Board sanction borrowing powers for the necessary works—viz.: Willans and Robinson, Rugby, engine, £1,115; Greenwood and Batley, Leeds, dynamo, £760; Electrical Power Storage Co., London, storage battery, £991; Spagnoletti and Co., London, switchboard, £314; Morris and Bastert, Loughborough, crane, £134; Johnson and Phillips, Old Charlton, cables, £1,402.

Cables.—Messrs. Johnson and Phillips, Old Charlton, report the following recent contracts: Belfast Borough Council, ·3 and ·1 vulcanised indiarubber cables; Eastbourne Corporation, high-tension concentric and low-tension triple-concentric paper-insulated cables; Gibraltar (Crown Agents for the Colonies), high and low tension concentric paper-insulated lead-covered cables, twin ditto, single ditto, and concentric and single vulcanised indiarubber cables; also for a quantity of junction boxes of various sizes.

BUSINESS NOTES.

TRACTION.

Perth.—About £500 is to be expended on tools for the repairing of the Corporation's tramway cars.

Manchester.—The Tramways Committee are considering the question of issuing weekly tickets.

Sunderland.—The Sunderland Tramways Committee are discussing the question of laying lines over the new Wear bridge.

Geneva Tramways Co.—The traffic receipts for the month of June, 1905, were 191,840fr., showing an increase on 1904 of 5,438fr.

Blackpool Electric Tramways (South).—A meeting of stock holders will be held at the Grand Hotel, Blackpool, on July 24 at 2.45 p.m.

Plymouth.—The Tramways Committee have been requested to consider and report upon the advisability of establishing a system of ½d. trams.

Paisley.—The Town Council have decided to approach the Paisley District Tramways Co. with regard to the establishment of a smooth service between the east and west ends of the town.

Stoke-on-Trent.—The Light Railway Commissioners have granted an application to the North Staffordshire Railway Co. for permission to use nine of its mineral branches for passenger traffic.

Digitized by Google

Ramsbottom.—Messrs. Butcher and Barlow intend to apply to the Board of Trade for an extension of time in which to carry out the provisions of the Ramsbottom Tramway Order of 1903.

Glasgow Tramways Bill.—The Glasgow Corporation (Tramways Consolidation) Order Confirmation Bill is opposed by the National Telephone Co., Renfrew County Council, and Dumbarton County Council.

Swiss Railways.—A Laffan telegram states that the big Oerlikon engineering works, in conjunction with the German firm of Siemens and Schuckert, have completed a project to substitute electric traction for steam on all the federal railways.

Blagdon and Pensford Light Railway.—An inquiry has been held by the Light Railway Commissioners with regard to the Blagdon and Pensford light railway at the Pelican Hotel, Chew Magna. The Commissioners agreed to recommend the granting of the order.

Rochester.—Owing to the success of the trams from Chatham to Rochester, the Corporation have decided to at once extend the system to Borstal, a rural part of the city, at an outlay of upwards of £20,000. Upon completion, the lines are to be leased to the Chatham Light Railways Co.

Burton-upon-Trent.—Mr. Rowland stated at the last Town Council meeting that the reduced tramcar service in the mornings had only resulted in a reduction in the receipts of £2 per week. Previously the receipts had dropped to 4½d. per car mile for the period mentioned, but now they were 6·20d.

Leith.—It is doubtful whether the first section of the electric tramways will be opened this month owing to delay in connection with the equipment. There is a proposal before a sub-committee that workmen's tickets, available at any time of the day, be issued in bundles at a rate of 10d. per dozen 1d. tickets.

Edinburgh Suburban Electric Tramways.—An inquiry will be held in the County-buildings, Parliament-square, Edinburgh, to-day, at 10.30 a.m. The order is one incorporating the Edinburgh Suburban Electric Tramways Co., and empowering that company to make and maintain tramways and other works, and for other purposes.

Reading.—Plans have been prepared and arrangements have been made for improving the tramway lines at the junction of London-street with London-road, and also at the corner of the Craven-road and London-road, where the sharp curves in the tramway lines have caused frequent delays and inconvenience. An expenditure of about £500 is required.

Aberdeen.—Colonel von Donop, of the Board of Trade, on Saturday inspected the new tramway line in Bridge-street and Guild-street, Aberdeen, and also the portions of the line that have been doubled in Holburn-street and King-street. He expressed himself satisfied with the lines, and it is understood that he will give his sanction for their use.

North Metropolitan Tramways.—A further section of the recently-electrified tramway system connecting Finsbury Park and Stamford-hill with Lower Edmonton was opened on Wednesday. This completes the electrification of the whole of the 8½ miles of tramways in Middlesex acquired by the Metropolitan Electric Tramways from the North Metropolitan Tramways Co.

Blyton and Frodingham Light Railway Order.—The Light Railway Commissioners have submitted to the Board of Trade for confirmation an order made by them for the construction of a light railway in the county of Lincoln from Blyton to Frodingham. Objections, addressed to the Assistant Secretary (Railway Department), Board of Trade, Whitehall-gardens, London, S.W., must be lodged with the Board on or before Aug. 4, 1905.

City to Waltham Abbey.—Mr. Gair Ashton's Committee of the House of Commons has passed the preamble of the North-East London Railway Bill, subject to the promoters constructing the tubes from the Monument to Hackney at such a depth as to admit of another pair of tubes being constructed above them. The workmen's fares between the City and Walthamstow must not exceed those charged by the Great Eastern Railway Co.

Woking and Bagshot Light Railway.—In consequence of an inquiry held on Monday, the Light Railway Commissioners have decided to recommend that the application of the West Surrey Light Railway Co. for the Woking and Bagshot Light Railway (Extension) Order be acceded to. This amended order only refers to 1½ miles of line between Horsell and Woking Junction, and to the erection of a generating station not exceeding 5,000-h.p. capacity.

Salford.—The total tramway receipts for the week ended July 17 amounted to £6 155, being about £1,500 more than the normal week's receipts, and the highest yet recorded. On the day of the Royal visit £1,405 was earned, and this also was a record for a single day's receipts. The traffic arrangements worked most satisfactorily, and, notwithstanding the large number of people who congregated each evening to witness the progress of the illuminated car, there has not been the slightest accident.

Devonport.—At a mass meeting held in the Victoria Park, Plymouth, to consider a resolution in regard to the Unemployed Bill, Mr. A. N. Stroud (Devonport) adversely criticised a system in connection with the tramways. This he described as follows: "Under that system if a man got 100 good marks he was entitled to a bonus of £1 a year, and if he got 100 demerit marks they entitled him to the sack." The marks were given by the inspectors. We need not trouble our readers with the rest of the remarks.

City and South London Railway Co.—The accounts for the half-year ended June 30 show a balance, after providing for the debenture stock interest, the payment of the dividend on the preference stocks, and the transfer to the renewal fund of £1,500, sufficient to allow the payment of a dividend on the consolidated ordinary stock at the rate of 2 per cent. per annum, carrying forward a balance of £1,041. The dividend for the corresponding period last year was at the rate of 2½ per cent. per annum, carrying forward a balance of £701.

Cannock Electric Railway.—An inquiry has been held into an application to the Light Railway Commissioners by the Wolverhampton and Cannock Chase Railway Co. for an order authorising them to construct and work their projected railway as a light railway. The line is to be worked by electricity for mineral and passenger traffic. This order does not give the company power to supply electricity to adjacent collieries, and they will be open to treat with companies for power to themselves. The Commissioners decided to recommend the granting of an order.

North-East London Railway Bill.—Mr. Ashton's Select Committee of the House of Commons have inserted in this Bill clauses requiring the promoters to provide for the construction of the railway in such a manner as to give an additional pair of tube tunnels. A section was also included to cause the powers of the company to cease unless half the share capital had been subscribed in a *bona fide* manner within 12 months of the passing of the Act. The promoters were likewise required to construct at least two stations in the City and to carry workmen from Forest-road, Walthamstow, to the City and back for 2d. by trains arriving at any of the City stations up to seven o'clock in the morning.

Maidstone.—The adjourned inquiry by Sir Herbert Jekyll into the provisional order granted by the Light Railway Commissioners for the extension of the tramway system in Maidstone to Loose, *viâ* Gabriel's-hill and Stone-street, and to Penenden Heath, *viâ* Week-street and Boxley-road, was concluded on Wednesday week. Sir H. Jekyll said he should not attempt to give them any intimation that day as to what the Board's decision would be. Major Pringle had been down since the previous hearing, and inspected the proposed route. His report, together with the evidence which had been taken, would help them in coming to a decision, which would be communicated to the proper authority as soon as possible.

Newcastle.—The Tramways Committee have decided by a majority of 14 votes to 3 not to use the cars for advertising purposes at the present time. A sub-committee is to wait upon the Tyneside Tramway Co. to confer with regard to the difficulty in connection with working the trams at Fisher-hill, Walker. The general manager (Mr. Ernest Hatton) has been asked to report regarding the use of tokens by tramway officials and other persons connected with the Corporation, as complaints had been made to the committee that these tokens were being used by many when not travelling on Corporation or tramway business. Mr. Hatton's first quarterly statement of the result of the working of the trams for the first 13 weeks of the present financial year shows a profit of about £6,000 for that period. Mrs. Hudson, who had been injured by falling from a tramcar, is to receive £100.

Belfast.—At the last Electricity Committee meeting it was reported that 94 new cars were ready, and it is expected that the full number will be completed by the time the new system is ready for opening. Mr. Courtenay, tramway advertising contractor, attended in regard to the matter of advertisements on the new electric tramcars. He explained that his lease expired with the old company, but that there were still two years to run on the original lease. He had paid £1,400 per year as rent, and as the lease was not continued, he would be at a great loss of money, as many of his contracts had not yet expired. The committee, while expressing themselves against the idea of permitting advertisements to appear on the new tramcars, agreed to allow Mr. Courtenay to fit up one of the new cars for the committee's inspection. Quite a number of the old tramway routes are now closed for reconstruction.

Swansea.—The Swansea Tramways Co. consider that they should be rated as railways generally as far as the portions from Port Tennant to Bryn-road and from Mansel-street to Sketty are concerned. The Corporation contend that they are rateable in full. When the matter came before the Swansea Finance Committee on Friday, it was reported that the Wakefield and District Light Railways Co., who operated about 20 miles of track in Wakefield and the surrounding district, had refused to pay the district rate in full, and the Wakefield Corporation suggested that Councils interested should join in paying the costs of a test case. The Finance Committee have agreed to contribute towards the cost of a test case, provided the facts on which the Wakefield case is fought are parallel to the Swansea case. Several towns and districts have agreed to support Wakefield, and other places similarly affected are inquiring what support has been given to the proposal. It was decided to accept the tramways company's quarter on account.

Cardiff.—At Friday's meeting of the Tramways Committee, Mr. J. W. Courtis, in referring to the accounts for the year ended March 31 last, said the expenditure was put down at £113 390, showing a deficiency of £1,181, but there was £1,500 charged for uniforms in last year's accounts, which would not occur again for two or three years, and there was an accident fund to which 2½ per cent. had been contributed, realising £2,605, although the expenditure out of this fund for the last three years had averaged under £800. There was a sum of £25,000 in the reserve fund, notwithstanding the fact that all repairs and renewals had been paid out of revenue. The receipts were about £2,000 below the estimate of the manager, Mr. Ellis, apparently due to the general depression in trade throughout the country. This year the improvement which had taken place during the last three month, owing to the rearrangement of fares and distances, would be felt to a very much larger extent. Last year the cars carried 24,000,000 passengers, or 133 times the population of Cardiff, reckoning that at 180,000. The car mileage was 275 000 miles. It might be interesting to know that out of the 24,000,000 passengers, 22,500,000 took 1d. tickets, and only 130,000 1½d. tickets. They had carried 3 000,000 passengers on the Splott to Olive-street route for an average of 7·78d. per car mile, and the expenditure was, including loan charges, 9·1d. per car mile. The running charges—that is, leaving out loans—worked

Digitized by Google

out at 5·8d. per car mile. The loan charges came to 3·3d., making the total 9·1d. The most profitable routes were Penylan, where the takings were 10·6d. per car mile, and Fair Oak-road, where the takings were 11·21d. per car mile. Broadway returned 10d. The committee agreed that some of the charges should be spread over two or three years, and in consequence, the accounts show a credit balance of £20. 17s. 6d., after setting aside £2,605. 5s. to the insurance fund, which now stands at £5,147.

Sheffield.—The report and accounts of the Corporation tramways for the year ended March 25, 1905, shows that a sum of £37,131 has been spent out of income in general repairs and maintenance during the year. The report shows the capital account as follows: capital expenditure to March 25, 1904, amounted to £988,316; deduct written off this year for depreciation of old horse track, £2,456—£985,860; expenditure during the year has been £57,721, showing a total capital expenditure to March 25, 1905, of £1,043,581. The income was £242,851. Receipts from passengers amounted to £240,565, an increase of £8 214. 7s. compared with last year. The total working expenses were £163,283, compared with £156,402 last year, an average cost of 6·477d. per car mile run. as compared with 6·507d. per car mile for the year ended March 25, 1904. After taking off £62,241 charges for interest on stock, mortgages, street improvements, sinking fund, etc., there is a surplus of £17,326 to be transferred to the accumulated surplus account. The following figures are available: total borrowing powers, £1,158,843. 12s. 4d.; borrowing powers exercised, £1,132 467. 15s. 2d.; unexhausted borrowing powers, £26,375. 17s. 2d.; gross capital expenditure, £1,135,565. 10s. 6d.; traffic revenue, £240,565. 16s. 11d.; working expenses, £163,283. 2s. 9d.; interest on capital, £40,027. 3s. 11d.; sinking fund, £23,954. 10s. 6d.; net balance, £41,341. 4s. 3d.; which has been disposed of as follows: sinking fund, £23,954. 10s. 6d.; depreciation, £60; surplus account, £17 326. 13s. 9d. Passengers carried, 63,952,283; total cost per unit, ·767d.; number of units used per car mile, 1·720; percentage of working expenses to receipts, 67·235; average traffic revenue per car mile, 9·543d.; average working expenses per car mile, 6·477d. Scale of fares—average distance: ½d. half mile; 2½ miles, 1d; average per mile, ½d. Number of cars in stock, 248. Total sinking fund, £138,829. 11s. 2d.; sinking fund applied in reduction of debt, £95,727. 15s. 3d.; reserve or renewals fund, £46,946. 10s. 6d.

London County Council. — The Highways Committee have submitted the following report: "The Council has recently decided to proceed with the construction and equipment of certain new tramways which have been authorised from time to time, and also with the reconstruction of the northern route of the late South London Tramways Company's system. It is, therefore, necessary to consider the question of obtaining the additional cars which will be required for use on these lines. In addition, the present car services can with advantage be considerably increased when the Greenwich generating station is opened, which will probably be early in 1906. For these purposes we suggest that steps should at once be taken for the supply of 150 cars. In connection with the tramcars used upon the Clapham route, there has been difficulty in arranging for the construction of roof covers that would pass under the bridges at Clapham and Balham, which have a specially low headway. As new cars have now to be purchased, we think that it will be desirable to arrange for the purchase of cars of a special type which can be utilised on the Clapham route as well as on the other lines. The type of car which we have inspected and suggest should be used for the Clapham lines has an inside headway of over 6ft. The cover is constructed for the whole of the car roof, ventilation being obtained by means of openings in the windows at either end as well as by the sliding glass sides. The arrangement of seats on the top of the car provides accommodation for two additional passengers. The staircases are of the direct pattern, and meet the views of the Commissioner of Police with regard to the side view of the motormen. The total expenditure is covered by the several estimates approved from time to time for the provision of cars in connection with the construction and reconstruction of tramways. We have arranged that the specification for the supply of the cars shall provide for the submission of alternative tenders for (1) the car bodies; (2) the car trucks; and (3) the motor equipments, etc., as we think that this will be an economic course to adopt and may facilitate delivery. We recommend (*a*) that expenditure on capital account not exceeding £126,000 be sanctioned in respect of the purchase of 150 double-decked, roof-covered electric cars for use on the London County Council tramways; (*b*) that the Highways Committee be authorised to obtain tenders, and to take the other preliminary steps necessary in connection with the obtaining of the cars referred to in the foregoing resolution."

Trams over Bridges.—It will be remembered that the second reading of the Bill in which the London County Council sought powers to construct and work tramways over Westminster and Blackfriars Bridges and along the Victoria-embankment, and joining up the existing lines on the Surrey side, was only saved in the House of Commons by the casting vote of the late Speaker, and the late Speaker sent it to a Select Committee, who passed it subject to an arrangement between the City Corporation and the authorities at Spring-gardens with reference to Blackfriars Bridge. Subsequently such an arrangement was come to at a prolonged sitting of the Court of Common Council. On Monday, Lord Newton unsuccessfully asked that this stage might be postponed until Thursday. He said the Bill had only just come before their lordships, and as he understood there was to be a motion for its rejection on the second reading, it was desirable that they should have a little more time to consider it. The Bill came before the House of Lords on Tuesday, and was rejected by a majority of 31, 97 peers voting. From a report in the *Daily Telegraph* we gather that Viscount Ridley said the leading feature of the Bill was most objectionable. Many attempts had been made to bring the tramways over the bridges, but till this year that power had invariably been refused. This year the second reading was only carried in the House of Commons by the casting vote of the Speaker. But the Bill now before them was a very different measure to the one which the House of Commons read a second time. It would do no good to anyone, would cause extraordinary inconvenience, and would retard that improved facility for traffic which they all desired. In the first place, it sought to connect on the other side of Westminster Bridge two existing tramlines, and when these would be running on a half-minute service over the bridge, it would be easy to imagine how greatly the ordinary traffic over the bridge to Waterloo Station would be interfered with. Then when the lines got over the bridge they would run on to the Embankment at a distance of only 2ft. from the pavement, an arrangement which would most seriously interfere with the traffic on this side of the bridge. Then it ran along the Embankment, on which for the purposes of beautifying London the ratepayers had spent a million not many years ago. Finally, it would turn on to Blackfriars Bridge, again at a distance of 2ft. from the pavement, and once more to the serious inconvenience of the traffic in that place. He was desirous of supporting the extension of tramways, and his opposition to this measure was not at all directed to the fact that these tramways were proposed by any particular body. If these lines were to connect the north with the south there would be something to say for the scheme, but that was the very part of the Bill which was thrown out by the House of Commons Committee. These lines were not only inconvenient but useless, and could not be carried out without further legislation, for before the County Council could proceed to construct them the City Corporation would have to obtain power to widen Blackfriars Bridge. This was clearly not a moment to add to the already existing complications of London street traffic by the multiplication of interests and systems of traffic, and so to create new difficulties. Nobody could say at this moment that the motor omnibus would not supersede the tramway. The Lord Chancellor said it was a mistake to say that the Commission was in favour of the scheme. What they did was to go with great care and minuteness into a system of tramways that might be arranged so as to be of great public advantage. They did not see the necessity of tramways across the bridges except as part of a great big scheme. In his opinion there was not sufficient case made out for the Bill. He regarded with considerable apprehension a scheme which would give to the County Council such enormous power, although he did not distrust the present Council. The traffic of London, which was always increasing, would be still further inconvenienced by such a system of tramways. Viscount Ridley has sent the following highly interesting letter to the editor of the *Times*: "Sir,—Will you allow me to make clear through your columns a point which no report of yesterday's proceedings on the London County Council's Tramways Bill in the House of Lords makes sufficiently apparent? The Bill dealt with several new tramlines, three of which were uncontested and not very important. I moved the rejection of the Bill because of two new lines only—those, namely, to be made across Blackfriars and Westminster Bridges and down the Embankment. In the course of debate it appeared that much importance was attached by the London County Council to certain new tramlines which nobody desired to oppose, but which, on the motion which I had made for the rejection of the Bill, would have suffered the same fate as the lines we did desire to oppose. I thereupon, at the suggestion of Lord James, offered to withdraw my motion and allow the second reading to proceed on the understanding that I should be allowed to move an instruction to the committee to strike out the tramlines to which objection was taken, thus allowing the uncontested tramlines to be gone on with. Objection was taken to this course by peers sitting on the front Opposition bench, and no option was accordingly left to me but to throw out the whole Bill. The responsibility, therefore, for delaying the construction of the lines which were said to be required, and which no one wished to stop, must rest on those members of the front Opposition bench who refused to come to an understanding which would have secured the passage of the uncontested parts of the Bill, while enabling us to throw out the lines to which we objected.—I am, yours faithfully, RIDLEY."

LIGHTING AND GENERAL.

Tewkesbury.—The Bill confirming the Corporation's electric lighting order has passed the Examiners.

Perth.—The Electricity Committee have fixed the price of current for the electric tramways at 1½d. per unit.

Cheshunt.—The North Metropolitan Electric Co. are applying for an order to supply electric light in Cheshunt.

Honiton.—Messrs. Purvis, of Exeter, intend to apply for a provisional order for the electric lighting of the town.

Loughborough.—The Corporation have decided to introduce electric light into another of the principal squares of the town.

Radiographic Station.—The *Globe* says that a permanent radiographic station has been established at Ferrol, in Spain.

Ince-in-Makerfield.—The United Electric Light and Traction Co. intend to apply for an electric lighting provisional order.

Devonport.—A special committee is considering the lighting of the borough, including the lighting by electricity of Marlborough-street.

Shepton Mallet.—The Shepton Mallet Gas Co. (Electric Lighting) Bill has passed the House of Commons Select Committee on Unopposed Bills.

Cheltenham.—At the last Town Council meeting the question of Mr. Kilgour's successor was mentioned, and was reserved for a special motion.

Dundee.—It is proposed to remove the electric arc lamps opposite the town's offices in Commercial-street, and substitute a special type of incandescent lamp.

Digitized by Google

Rugby.—An inquiry has been held into the application of the District Council for powers to borrow £450 for street-lighting and £2,000 for electric lighting.

Penzance.—It is proposed to empower a small committee to act in connection with the Penzance Electric Lighting Co. in obtaining an electric lighting provisional order.

South London Electric Supply Co.—The sale of current for the quarter ended June 30 last amounted to £16,620 against £15,654 for the corresponding quarter of last year.

Armstrong College, Newcastle-upon-Tyne.—Matriculation and exhibition examinations begin Sept. 25. Lectures begin Oct. 3, 1905. Full particulars appear in our advertisement columns.

St. Marylebone.—Plans by Mr. F. A. Wilkinson, electrical engineer and manager, showing positions of feeder pillar boxes it is proposed to erect in the streets of the borough, have been agreed to.

Stafford.—Arrangements are being made with the Tudor Accumulator Co. for the renewal of the battery at the electricity works during the current financial year, the estimated net cost being £800.

Whitehaven.—The Brush Electrical Engineering Co. intend to apply to the Board of Trade for a provisional order to supply electric energy for public or private use within the area of the borough.

Eton.—An application by the Postmaster-General for consent to place an underground telegraphic line along the road from the Council's boundary at Salt-hill to the Slough Post Office has been granted upon the usual terms.

London Electric Supply Bills.—The County of London Electricity Supply Bill was on the 19th inst. ordered to be reported for third reading. The Central Electric Supply Bill will come before the Committee to-day.

Lowestoft.—The Town Council have decided to oppose that part of the telephone agreement which proposes to give the company power to lay underground cables in any part of the country without permission of the local authorities.

Dalkeith.—The minutes of the previous monthly meeting were confirmed on Monday after a prolonged discussion. They referred to a refusal to entertain a proposal of the Electric Supply Corporation to extend the public electric lighting along the Bonnyrigg-road.

Outing.—The employés of the Electrical Co. held their annual outing at the Crown Hotel and pleasure gardens, Broxbourne, Herts, on Saturday, July 1. Sports were held during the morning, and a number of excellent prizes were secured by successful candidates in the different races, etc.

Northampton Institute.—Full day courses in the theory and practice of mechanical, electrical, and horological engineering will commence on Monday, Oct. 2, 1905. Entrance examination on Wednesday and Thursday, Sept. 27 and 28. Full particulars in our advertisement columns.

Truro.—Four firms intend to apply for a provisional order to supply electricity within the Council's area. The Electric Light Committee's report recommending the Council to permit a company to instal the electric light in the city, the Corporation applying for the necessary provisional order on terms to be agreed upon, has been rejected.

Tiverton.—As nothing further has been heard from the Local Government Board with respect to the loan applied for for the electric lighting scheme, the Government inquiry into which was held nearly a year ago, the Council have decided to send a deputation to the Board to ascertain definitely whether or not the loan would be sanctioned.

Falkirk.—The British Electric Plant Co., Alloa, have obtained an order from the Corporation for the complete equipment of electric motors for their new gasworks. These gasworks are probably the first in Great Britain to be completely and exclusively driven throughout by electric motors. The current will be supplied from the Corporation electric supply station.

New Issue.—Subscriptions are invited at par for 23,000 shares of £1 each in the "Otto" Electrical Manufacturing Co. (1905). The company, which has a capital of £75,000, has been formed to acquire and extend the business of the "Otto" Electrical Manufacturing Co. The business consists of the machinery and plant and patents belonging to the old company. There are works at Stockport-road, Longsight, Manchester.

Stock Exchange.—Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to Durham Collieries Electric Power Co.'s 100,000 6 per cent. cumulative preference shares of £1 each. The committee have been asked to allow Sunderland District Electric Tramways £160,000 5 per cent. first mortgage debentures of £100 each to be quoted in the official list.

Brighton.—The accounts of the electricity undertaking for the past year show a gross profit of £36,565. The net surplus, after providing for all charges, including interest on capital and sinking fund, contributions for the redemption of debt, is £5 381. This sum it is proposed to carry to the reserve fund, which will then amount to £21,112. The number of consumers at the end of the year under review was 4,256, against 4,037 in the previous year.

Edinburgh.—At the Town Council's last meeting the recommendation with regard to the distribution of the £21,000 balance on the electric lighting accounts was carried, with the amendment that the £4,000 be credited to the relief of rates instead of the streets account, as formerly proposed. Mr. Macpherson pointed out that the 7,250 consumers of current, who had contributed £119,350, had already paid their quota towards the maintenance of the streets.

Accidents.—At the Westinghouse power station at Neasden, John O'Malley, electrician, Willesden, and a boy named Martin Ruddy, of Willesden, on entering one of the transformer chambers became entangled in live wires. O'Malley was instantly killed, and Ruddy, who was badly burned, was removed to the hospital. Late on Sunday night an accident occurred on the Birmingham and Midland Tramway Co.'s electric tramway at Oldbury. A car conveying about 25 passengers fell over on its side through missing the points at a loop. Fourteen of the passengers on the top of the car were injured. We understand that after being attended by medical men on the spot they were all able to return to their homes.

Islington.—It is proposed to alter the sliding scale of 7d. per unit for the first hour's daily consumption throughout the quarter at their maximum demand in the quarter and 4d. per unit for all consumption beyond to a sliding scale of 7d. and 3d. per unit respectively. Further, it is proposed that the present uniform rate of 5d. per unit for lighting be reduced to 4d. per unit; that the price to private consumers for arc purposes be 3½d. per unit; that the present rates for the supply of electricity for power, heating, and cooking purposes be altered from 2d., 1½d., and 1½d. to a uniform rate of 1d. per unit; that the time limit in the case of supply of electricity for power be abolished; that the rate be uniform throughout the 24 hours; that a discount of 2½ per cent. be allowed on all quarterly accounts exceeding £5, and of 5 per cent. on all quarterly accounts exceeding £10, provided such accounts are paid within 14 days of presentation; and that the foregoing charges take effect as from the end of next September quarter.

J. G. White and Co.—This well-known contracting company, which has constructed the permanent way and other electric traction and supply equipments for a large number of important undertakings in the United Kingdom and abroad, is about to offer for subscription 5,000 6 per cent. preference shares of £10 each, making its total capital £200,000. The contracts actually completed since the formation of the company in 1900 represent an aggregate value of £2,113,200, while further contracts have been secured and are now in hand equal to £1,779,000. The proceeds from the present issue are to be used to extend the general business of the company and partly to complete the Ritz Hotel, now under construction by the Waring-White Building Company. The preference shares are entitled to a further share of the profits up to 12 per cent. after the ordinary shares have received 6 per cent. The actual rate already paid has ranged from 6 to 10 per cent. Further details of the issue will be found elsewhere. The list will close on or before July 27, 1905.

Bermondsey.—Mr. Heenan, the newly-appointed borough electrical engineer, took up his duties on Friday, June 30. The Electric Lighting Committee have expressed their high appreciation of the manner in which Mr. Doran, the chief assistant electrical engineer, had superintended the undertaking between the departure of the former chief engineer and the arrival of his successor. The committee recommended that his salary be increased to £200 per annum, but in consequence of a standing order of the Council applications for increase can only be considered in February of each year. The highest load observed in June was 432 kw., as against 209 kw. for the corresponding month of last year. The expenditure of the year ending March 31, 1905, was £10 875 and the income £12 015. The cost per unit sold for coal and fuel was ·45d.; for oil, waste, water, and engine-room stores, ·04d.; wages, ·16d.; repairs, ·08d., or a total works' cost of ·73d. The committee estimate that the expenditure for the year ending March 31, 1906, is £16,208, and the outgoings £13,906 or a surplus on the forthcoming financial year of £2 302. From Oct. 1 next the charge for power purposes is to be 1½d. per unit for the first four hours' average daily use of the maximum demand, and ¾d. per unit for all electricity consumed after.

Institute of Marine Engineers.—The Institute of Marine Engineers on July 15 visited the United Asbestos Co.'s works at Hatefield. The works are excellently situated on the banks of canal, which affords a means of transit for goods, and the employés carry on the work under conditions which contrast favourably with those within the confines of a densely-populated district, while the employers are more free from the burden of taxes which in many cases is a factor to be considered in making a business a profitable investment, or a municipality the poorer for the lack of it. The process of manufacture of asbestos is of considerable interest, and may be briefly described. Blocks of the crude asbestos are placed in a crushing machine where the fibres are separated. These are then sorted out and taken to different departments according to their suitability. In one department the fibres are spun into yarn and afterwards woven into cloth, or interwoven with wire and made into various forms of packing for steam glands. The spinning and weaving machines attracted a great deal of attention. The manufacture of joints for manhole doors and covers was watched with keen interest, as was also the making of asbestos millboard from the pulp, which is deposited on blankets, and is from thence taken up by a specially prepared roller on which the pulp is deposited to a desired thickness, shown by a gauge suspended from a bracket. The sheets of millboard are then cut and ready for drying. The laboratory is a special feature in connection with the works, where careful tests are carried on to prove the quality of asbestos, indiarubber, and other raw materials used in the manufacture of the various articles. After the inspection the party was grouped, and a photograph taken, and a souvenir of the visit presented to each member of the party, which contained samples of asbestos in its various stages of manufacture. After luncheon a vote of thanks was accorded to the United Asbestos Co. for their kindness, regret being expressed that Mr. Fisher, the secretary and general manager, had not returned from abroad in time to preside over the gathering. Mr. Hawkridge, the assistant manager, acting in his stead. A vote of thanks was also given to Mr. McCallum, the works manager, and his staff for the explanations which were so freely given to enquiries. A very interesting paper dealing with this subject was read by Mr. S. H. H. Barratt, A.M.I.C.E., lubricant and boiler covering manager, who gave particulars of numerous tests.

Digitized by Google

Arlecdon and Frizington.—At the last District Council meeting an offer was favourably discussed in which it was stated that the West Cumberland Electric Power and Tramways Company were about to start almost immediately to lay the road and generating station, from which current would be supplied at very reasonable rates to all parts of West Cumberland.

Telegraph Clerks.—The Liverpool Branch Committee of the Postal Telegraph Clerks' Association have passed a resolution deprecating the language used by the Postmaster-General in the House of Commons on the occasion of the debate on the Post Office Estimates on the 6th inst., and emphatically repudiating his charges of "blood-sucking" and "blackmailing" by Post Office servants.

Opening of Manchester Dock.—Messrs. Dorman and Smith inform us that the switch used to open the new dock at Manchester by his Majesty the King on the 13th inst. was made for the Ship Canal Company by them. This switch was one of their "C" type. They point out that their switches are good enough for kings as well as strong enough for navvies. The actual switch used by his Majesty is now to be seen in Messrs. Elkington's window, St. Ann's-square, Manchester.

Fire.—In reference to the slight fire which occurred at Verity's Limited on Saturday, we are informed that fortunately the damage done is of the most trivial description, and in no way interferes with the ordinary course of the business. The portion of the premises affected is only a skylight in the centre of one of the fittings showrooms, underneath which some drapery caught alight, presumably due to spontaneous combustion, caused by the heat rays of the sun on an uneven piece of glass.

Walsall.—According to the last report the total number of consumers supplied on June 30 last was 419. During the past month the total units generated at the station was 106,980. The total output from the main generators were 103,530 units. The total units from the transformers were 79,728 (estimated). The total units registered on the meters were 79,232. The machinery was run for 686 hours. The wages paid amounted to £124. Sanction has been received to the borrowing of £1,350 for electric lighting purposes.

Swanage.—At the last meeting of the Urban District Council letters were read from Cecil Cooper and Co., electric light and power engineers and contractors, 14, Gloucester-road, South Kensington, London, S.W.; Foot and Milne, electrical engineers and contractors, Princess-mansions, 66, Victoria-street, S.W.; and the Bournemouth and Poole Electricity Supply Co., Moorgate-court, Moorgate-place, London, E.C., stating that it was their intention to apply during the ensuing session of Parliament for electric lighting provisional orders within the district.

King's Lynn.—The engineer's last report shows new applications for 305 8-c.p. lamps, making a total of 21,279 from private consumers, and four additional consumers, making a total of 523. The following figures are available: **May**, 1905—units generated, 30,795 (1904, 28,424); total units sold to private consumers (light and power), 14,769 (13,534); units sold at lighting rates, 5,541 (4,525); units sold at power rates, 9,228 (9,059); cost of fuel, stores, repairs, and wages at station, £118. 4s. 7d. (£118. 15s. 2d.); cost per unit generated, 0·9215d. (1·0027d.); wages of lamplighters and outside staff, £28. 14s. 11d. (£28. 10s. 9d).

Radcliffe.—The electrical engineer's last report shows that the electricity generated during May was as follows—viz.: lighting section, 5,100 units; tramways, section No. 1, Stopes and Black-lane, 8,453 units; No. 2, Blackburn-street, 3,814 units; No. 3, New-road, 3,454 units—total, 15,721 units. During the month the works had worked satisfactorily. The Council have refused the Lancashire Electric Power Co. permission to supply electricity to The Hawthorns, Ringley-road, but have confirmed the arrangement made by the surveyor with the company to allow them to carry their cables over the canal by means of the Council's footbridge, on payment of a wayleave of 5s. per annum.

St. Pancras.—The Borough Council has for some time supplied electric current for motive power at 1d. per unit during five hours of the day, and they have now decided to charge up to 24 hours the same rates as those specified in the Administrative County of London and District Power Bill, ranging from 0·94d. per unit for six hours to 0·609d. per unit for 24 hours—*i.e.*, 1½d. per unit for the first two hours' average use per day of the maximum demand and ½d. per unit for all in excess of this. This works out at 1d. per unit for a five-hour regular load per day. Factories using current will be allowed after Aug. 1 to light their premises at 1d. per unit up to 20 per cent. of the units they have used for power.

Underground Telegraph.—The Middlesbrough Chamber of Commerce last week discussed a letter in which Lord Stanley said that there was no present intention of continuing underground telegraph lines northwards from Leeds. Edinburgh would be reached by an extension of the main line, and not through the North-East Counties. The secretary referred to a statement made by Mr. Austen Chamberlain, as Postmaster-General in 1903, in a communication to the Associated Chambers of Commerce, which was to the effect that the pipes would be extended to Carlisle, Bradford, and Leeds, and eventually to Newcastle and other Tyneside towns. It was decided to call the Postmaster-General's attention to this discrepancy between his statement and that of his predecessor.

Birmingham.—The Electric Supply Committee have had under consideration several important questions relating to works of extension rendered necessary by the Corporation tram scheme. The site of the old General Hospital in Summer-lane is being utilised for the provision of a large generating station, but in order to furnish the several tram routes with the required electrical power when the Corporation takes over the trams, it will be necessary to provide several sub-stations centrally situated so far as the several routes are concerned. Thus for the Dudley-road section it has been decided to erect a sub-station in Rosebery-street, and other similar stations are to be established in Upper Trinity-street and Lower Edward-street. The expenditure for which the committee will ask authority will be about £50,000.

London Gazette.—The partnership between Joseph Blanchet Rowell and John Arthur Henderson, electrical engineers and contractors, 19, Old Queen-street, Westminster, has been dissolved by mutual consent. Thomas Hindle, chartered accountant, District-chambers, Darwen, has been appointed trustee in the estate of Alexander Holmes and Alexander McCallum, electrical engineers, Crown Works, Darwen. Arthur Samuel Cully, 24, Railway-approach, London Bridge, S.E., has been released from trusteeship in the estate of William Denham, electrical engineer, 5, Century-buildings, London-road, Croydon, Surrey. The partnership between William George Leather, Thomas Hanson Cockin, and William James Riley, trading as the Windus Electric Company, at 25, Howard-street, Sheffield, has been dissolved, and the business will be carried on by the said William George Leather solely.

Bath.—Mr. Evans's notice of motion has been withdrawn. It reads as follows: "That in consideration of the excessive charge now made for the public electric lighting in Bath, it is desirable in the interest of its ratepayers that the charge per lamp be immediately reduced by one-half—viz., £12 each for the large arc lamps, and all smaller lamps charged proportionately, or failing this reduction, gas be substituted for lighting the whole area now lighted by electricity." He asked for permission to withdraw the last part from the words "proportionately" to the end. At the last Town Council's meeting a report of a special committee was adopted, recommending that the Surveying Committee be asked to provide private lines between the surveyor's office and the destructor works, the stables, and Dog-lane and Greentree yards; and that when these are constructed the present National Telephone service for the destructor works be discontinued. The cost of the whole of the work in connection with the lines is not to exceed £120, and the upkeep is estimated at from £4 to £5 per annum.

PROVISIONAL PATENTS, 1905

JULY 10.

14146. Improved means for controlling the trolley arms of electric tramcars. John Coleman Fergusson and Frederick Hitch, 128, Colmore-row, Birmingham.

14196. Improvements in or relating to Rontgen tubes. Kurt August Steizel, 111, Hatton-garden, London. (Date applied for under Patents Act, 1901, July 11, 1904, being date of application in Germany.) (Complete specification.)

14208. Improved electrical switch apparatus for supplying current-consuming devices on several motorcars of electrically-propelled trains. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers Southampton-buildings, Chancery-lane, London. (Siemens-Schuckertwerke G. m. b. H., Germany.) (Complete specification.)

14209. Improvements in apparatus for supplying electrical energy to a network by the aid of an auxiliary current generator and an auxiliary line wire. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens-Schuckertwerke G. m. b. H., Germany.) (Complete specification.)

14210. Improved regulating switch apparatus for increasing or decreasing the pressure of a network in finely-divided stages. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens-Schuckertwerke G. m. b. H., Germany.) (Complete specification.)

14211. Starting apparatus with controller drum for induction motors. Siemens-Schuckertwerke G. m. b. H., Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Aug. 3, 1904, being date of application in Germany.) (Complete specification.)

14214. Improvements in electric furnaces. Fredrik Adolf Kjellin, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, July 11, 1904, being date of application in Switzerland.) (Complete specification.)

14221. Improvements in means for producing current or radiations for a transportable wireless transmitter station. William Phillips Thompson, 6, Lord-street, Liverpool. (Gesellschaft fur drahtlose Telegraphie G. m. b. H., Germany.) (Complete specification.)

14222. Improvements relating to the suspension of electric motors of locomotives. British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States. (Complete specification.)

JULY 11.

8886a. Improvements in wireless telegraph transmitting apparatus. Harry Shoemaker, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Rule 9, April 27, 1905.) (Complete specification.)

8886b. Improvements in wireless telegraph receiving apparatus. Harry Shoemaker, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Rule 9, April 27, 1905). (Complete specification.)

14356. Electric heating cartridges. August Voelker, 100, Wellington-street, Glasgow.

Digitized by Google

14293. Improvements in electrical heating apparatus. Charles McIntyre and Alfred Upton Alcock, 1, Queen Victoria-street, London.

14297. Improvements in surface-contact electric traction systems. Edward Albert Mitchell and the Dolter Electric Traction, Limited, 46, Lincoln's-inn-fields, London.

14314. Improvements in or relating to microphone apparatus for telephone and other circuits. Quirino Majorana, 111, Hatton-garden, London. (Complete specification.)

14317. Improvements in polyphase commutating machines. The Elektricitäts Act. Ges., vormals W. Lahmeyer und Co., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, July 11, 1904, being date of application in Germany.) (Complete specification.)

14318. Improvements in and relating to electric ignition gear for explosion motors. Gustave Cornilleau and Auguste Sainte-Beuve, 323 High Holborn, London. (Date applied for under Patents Act, 1901, Dec. 29, 1904, being date of application in France.) (Complete specification.)

14320. Improvement in single-phase alternating-current motors. Siemens-Schuckertwerke G. m. b. H., Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Dec. 13 1904, being date of application in Germany.) (Complete specification.)

14333. Improvements in electric furnaces. Paul Girod, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JULY 12.

6640a. Improvements in and relating to electricity meters. Carl Wilhelm John Busch and Hugo Roosen, 65, Chancery-lane, London. (Date applied for under Patents Rule 9, March 29, 1905.)

7822a. Improvements in and relating to controllers for electric motors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Date applied for under Patents Rule 9, April 12, 1905.)

12160a. Electrolytic process for obtaining fixed gases from any suitable carburant. Alexandre Auguste Eveno, 65, Chancery-lane, London. (Date applied for under Patents Rule 9, June 10, 1905.)

14345. Improvements in or relating to electric switches for use in connection with motor controllers, and for analogous purposes. The Electric and Ordnance Accessories Company, Limited, Robert Frederick Hall, and Joseph Richardson Garner, 24, Temple-row, Birmingham.

14366. Improvements in electric sparking plugs for internal-combustion engine ignition. Rankin Kennedy, 60, Norse-road, Scotstown, Glasgow.

14390. Improvements in the manufacture of electrical resistances. Charles Ruzicka, Olun House, Surrey-street, Strand, London.

14401. Improvements in alternate-current induction motors. Louis John Hunt and the Sandycroft Foundry Company, Limited, 6, Lord-street, Liverpool.

14417. Improvements in and relating to electrical connections for accumulators, induction coils, sparking devices, and the like. William Gard, 18, Southampton-buildings, Chancery-lane, London.

14420. Improvements in electrically-operated cranes, hauling gear, and similar appliances. George Robert Hingeberg, Daniel George Jones, Frederick Lawrence Berry, and Ellis Middleton, 47, Lincoln's-inn-fields, London.

JULY 13.

14441. Improved means for suspending and sustaining electric lamps and the like at any desired height. William Whitaker, jun., and Arthur Bright Wass, Fife House, Kingston-on-Thames. (Date applied for under Patents Act, 1901, July 14, 1904, being date of application in United States.) (Complete specification.)

14457. Improvements in and connected with electromagnetic annunciators acting simultaneously as choking coils. Hermann Oppenheimer, 55, Redcross-street, Barbican, London. (Akt. Ges. Mix und Genest, Germany.)

14461. Improvements in electric organ actions. Henry Charles Edward Jacoby, 21, Finsbury-pavement, London.

14465. Improvements in automatic cut-outs or switching devices for electrical indicating means. George Harrison, 11, Southampton-buildings, Chancery-lane, London. (The Electric Railway Improvement Company, United States.) (Complete specification.)

14466. Improved electric apparatus for interlocking electric signals and points. Edmond Meyer Tudor Boddam, 23, Savernake-road, London.

14471. Improvements relating to switching devices for use in electric flash advertising. Leonard Kingswill Job, 322, High Holborn, London.

14483. Improvements in automatic electric switches. James Joseph Coachman, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

14490. Improvements in and relating to electric switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

14491. Improvements in incandescent electric lamps and methods of making the same. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

JULY 14.

14496. Improvements in electrolytic or liquid resistance apparatus for electric regulators, electric motor starters, or the like. Hugo Hirst and Charles Samuel Mathew Medlen, 71, Queen Victoria-street, London.

14511. Improvements in electricity meters. Sydney Holmwood Holden and Chamberlain and Hookham, Limited, 4, New Bartholomew-street, Birmingham.

14518. An improved system of electric ignition for gas or petrol engines and the like. Walter Shelverton Frost, 135, High-street, Homerton, London.

14526. Improvements in arc lamps. Bernard Mervyn Drake, 66, Victoria-street, Westminster, London.

14550. Improvements in or relating to electric alternating-current switches. Charles William Scott Crawley, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

14555. Improvements in devices for protecting electric distribution systems and apparatus against reversal of energy. The British Thomson-Houston Company, Limited, and Jonathan E. Woodbridge, 83, Cannon-street, London.

14566. Improvements in and relating to electric circuit interrupting devices. The British Thomson-Houston Company, Limited, and Edmund Basil Wedmore, 83, Cannon-street, London.

14567. Improvements in methods of regulating alternating-current dynamo-electric machines. The Allgemeine Elektricitäts-Ges., 83, Cannon-street, London. (Date applied for under Patents Act, 1901, July 15, 1904, being date of application in Germany.) (Complete specification.)

JULY 15.

14582. Improvements in or relating to low-tension electric ignition mechanism for internal-combustion motors. James Sidney Critchley, Woodbury, Church-road, Shortlands, Kent.

14612. Improvements in apparatus for use in combination with electric stop motions as used on drawing, slubbing, and other similar machines for preparing and spinning cotton and other fibrous materials. Thomas Chadwick, Penny Bank-chambers, Halifax.

14614 Improved electric stop motion for drawing, slubbing, and intermediate frames. Tom Schofield, 254, Colne-road, Burnley.

14615. Improvements in and relating to electric arc lamps. Crompton and Co., Limited, and Arthur John Hodgson, 55, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Aug. 3.

1904.

10748 Dynamos or the like. Vandervell and Proctor.

15312. Means for the manufacture of brasses or bushes for the bearings of shafts, axles, or the like, more especially applicable to electromotors. Tomson and Hanna.

15344. Automatic safety device, particularly applicable in connection with falling overhead trolley wires, or other wires passing over or running parallel with same Berry and Rush.

15384 Memorandum and like appliances for use in connection with telephones and for other purposes. Gamble.

15386. Mechanical and electrical elevator for goods, especially goods contained in sacks. Rubaudo, Estier, Estier, Mallet, and Mouren.

15455. Electric relays for automatic circuit breakers and the like. Field, Garrard, and Ferranti Limited.

15599. Electric alarm for indicating the heating of bearings. Thomson.

15627. Electric clocks Bowell.

15796. Alternating electric current distributing systems. Metz and Price.

16728. Compounding dynamo-electric machines for three-wire systems. (Allgemeine Elektricitäts-Ges. (Date applied for under International Convention, July 31, 1903.)

17016. Control systems for electric translating devices, particularly adapted for use for controlling motors on electrically-propelled vehicles British Thomson-Houston Company, Limited. (General Electric Company.)

17425. Self-regulating dynamo-electric machines. Rosenberg and Rosenberg.

17674. Telephones. Port.

17813 Systems of electric motor control. British Thomson-Houston Company, Limited. (General Electric Company.)

18646. Electric plug and socket couplings. Richert.

18317 Electric switches. Kennedy-McGregor, and Wren.

18378 Combined electric switches and fuses. Hornby.

18840. Processes of electro-deposition. British Thomson-Houston Company, Limited. (General Electric Company.)

Digitized by Google

18546. Electric incandescent lamps whereby two or more lamps are governed by one central connecting cap, or the like. Byng and Crawshaw.

18592. Electric railways. Carolan. (General Electric Company.)

19365. Metallic conduits for electric wires and cables. Isherwood.

19390. Casing or conduit for electric conductors. McHardy.

20783. Electrical telegraphs and controlling apparatus. Vyvyan and Newitt. (Secret document under Sec. 44, Patents, etc., Act, 1883.)

21217. Automatic telegraphic apparatus. Damaskinos.

22905. Electro-thermic fans. de Mare.

29145. Space telegraphy. Stone. (Date applied for under International Convention, April 11, 1904.)

29146. Support for aerial conductors used in space telegraphy. Stone. (Date applied for under International Convention, May 3, 1904.)

1905.

1072. Incandescent electric lamps. Gerow and Gerow.

1583. Induction regulators for electric currents. Finzi. (Date applied for under International Convention, Jan. 27, 1904.)

3525. Apparatus for producing electric reactions in gases by aid of electric arcs Birkeland. (Date applied for under International Convention, Feb. 20, 1904.)

3913. Apparatus for enabling telephonic and telegraphic messages to be transmitted over the same line. Turchi and Bruné. (Date applied for under International Convention, April 2, 1904.)

5220. Vapour electric lamps. Thomas. (Date applied for under International Convention, March 28, 1904.)

8253. Electric light hanger for walls. Lau. (Date applied for under International Convention, April 25, 1904.)

NOTES.

Junior Institution of Engineers.—Mr. Dugald Clerk, M.I.C.E., the well-known gas-engine expert, has been elected president of the Junior Institution of Engineers for the ensuing session.

University Grants.—Parliament is asked to grant £100,000 in aid of university colleges for the year 1905-6. The proposed grants are as follows: Manchester, £12,000; University College, London, £10,000; Liverpool, £10,000; Birmingham, £9,000; Leeds, £8,000; King's College, London, £7,800; Newcastle-on-Tyne, £6,000; Nottingham, £5,800; Sheffield, £4,600; Bedford College, London, £4,000; Bristol, £4,000; Reading, £3,400; Southampton, £3,400; Dundee, £1,000—£89,000. The remaining £11,000 will be reserved for distribution in March next.

Single-Phase Traction.—The French Westinghouse Company, having its headquarters in Paris, have recently secured another important contract for the equipment of an Italian railway on the single-phase system. The line in question is the Bergamo-Valle Brembana Railway. The length of the road will be 20 miles. It will be served by five 30-ton locomotives equipped with four single-phase motors of 75 h.p. capacity each, with multiple-unit control and pneumatically operated bow trolleys. The value of the contract is said to be £300,000. It will be remembered that the same company are equipping the Rome-Civita Castellana Railway on the single-phase system.

The Central Electric Supply Bill.—The Bill by which the Central Electric Supply Company seek to build a large generating station alongside the Regent's Canal in St. Marylebone in order to supply electricity to that borough, to Hampstead, Paddington, Westminster, St. Pancras, Holborn, and adjoining parishes, was to have been discussed before the House of Commons committee of which Sir A. H. Brown is chairman. This has been avoided by an agreement with the Corporation of St. Marylebone, under which the electricity generated at the new station is only to be supplied through the Westminster and St. James's Electricity Supply Companies. These are the real promoters, as the Central Electric Supply Company was formed to give a bulk supply to them. An agreement was also come to as to the buildings with the London County Council, which will allow of the Bill passing the committee.

Electric Fire-Alarms.—From an Aberdeen paper we glean the following facts as to the automatic action of the May-Oatway fire-alarms. One night last week an outbreak of fire had occurred at the meal mill in Berryden, belonging to the Northern Co-operative Company. The fire was caused by an over-heated bush on the first floor of the mill, and at once the May-Oatway alarm automatically notified the fire brigade of the outbreak. Nothing was known at the mill about the fire until a telephone message was received from the fire brigade station. On receipt of the information steps were instantly taken to put out the fire, and the result was that by the time the brigade had arrived the flames were extinguished. The fire would in all probability have been a serious one, owing to the nature of the surroundings and the character of the woodwork, had not a quick alarm been given by the automatic installation.

Strand-to-Angel Tramways.—We referred last week to the proposals of the London Traffic Commission for the increase of through tramway traffic in London. The Highways Committee of the London County Council have now recommended the completion of a line from the Strand to the Angel at Islington, which will form eventually an important link in the series of connections in question. We give in the "Traction Notes" more particulars of this tramway, which will run from the Strand through the subway under the new street to Holborn. It then comes to the surface and the electric cars will proceed on the lines now leased by the North Metropolitan Tramway Company. The only thing which can be urged against the scheme is that it stops at the Strand instead of continuing along the Embankment and over the bridges to the trawway system south of the Thames. For this defect the House of Lords are responsible.

The Faraday House Journal.—The last issue of this journal, which is run by the students at Faraday House, contains an interesting *résumé* of the history of the institution. An illustration is given of the house in Red Lion-square where the Hammond Electrical Engineering College was located from 1882 to 1885. Other homes of the institution are illustrated, and finally a good description is given of the new premises in Southampton-row, which were opened in May last. The success of students who have passed through the institution is shown by the number of prominent electrical engineers who obtained their first knowledge of electrical matters at one or other of the buildings in question. With the new laboratories the facilities for experimental work will enable a higher class of instruction to be given, and also a large number of students can be provided for. The standardising department is also enlarged, and in this good work should be done in the future as has been the case in the past. The journal contains a number of interesting notes as to the work being done by past students.

New Books.—Prof. Robert H. Smith, A.M.I.C.E., M.I.M.E., M.I.E.E., etc., has just published a large volume, profusely supplied with curves and tables, on "Commercial Economy in Steam and other Thermal Power Plants, as dependent upon Physical Efficiency, Capital Charges, and Working Costs." Mr. H. Malcolm Hodson, A.M.I.M.E., is responsible for the diagrams. The work is published by Archibald Constable and Co., Limited, 16, St. James's-street, Haymarket, at 24s. net.—We have also received from Harper Bros. a volume just published on "Electric Traction," by the same author, who in his preface says that he has restricted his remarks entirely to the subject of traction, with the exclusion of all explanations of electrical machinery and electrical action that are general and common to the whole of electrical engineering. The author has purposely kept within the range of things actually and successfully accomplished on a commercial scale in Europe. He has, therefore, merely made mention of proposals for single-phase traction, and has devoted only a short part of one chapter to electric traction on common roads.

St. Marylebone Smoke Nuisance.—The Public Health Committee of the Borough Council of St. Marylebone have received a report from the medical officer of health as to a nuisance caused by the smoking of the north shaft of the Council's new generating station at Richmond-street. Mr. Arthur Wright has stated that this is not caused by using an improper sort of coal, but is entirely due to having to raise steam prior to the completion of all the auxiliary apparatus, and that when the mechanical stokers are used there will be no need to fear any reasonable complaint being made on this subject again, and that the mechanical stokers will be in position very shortly. The committee are not satisfied with this, and decided that in view of the fact that the nuisance remains unabated, and also having regard to the difficult position of having to deal with other offenders of like nuisances, who are naturally taking advantage of the position, all the facts sholud be reported to the Council, with a view to securing that the nuisance caused by the emission of black smoke from the

Digitized by Google

north shaft of the electric generating station in Richmond-street be permanently abated. It seems likely, therefore, that the Council may decide to issue a summons against itself.

New Zealand International Exhibition.—The Government of New Zealand has decided to hold, during the summer of 1906-7, an international exhibition at Christchurch, Canterbury, New Zealand, in which all the nations of the world have been invited to participate. The object of the exhibition is educational, and it is intended to demonstrate the resources and possibilities of the colony as one of the world's food-producing factors, and its vast mineral resources. The exhibition will open in November, 1906, and remain open until the early part of April, 1907. It is also intended to bring under the notice of the more industrial nations of the world the great field the colony of New Zealand offers as an outlet for enterprise and for the use and consumption of all manner of up-to-date appliances and manufactures. The exhibition buildings will be erected in Hagley Park, Christchurch, where some 400 acres are available. The advantages the colony possesses as a tourist resort will be brought to the notice of visitors to the exhibition. The full programme of the various departments is not yet to hand. Applications for space should be sent to the secretary of the Local Committee at Christchurch. There are good openings for electric power plant in the colony in the development of its mineral wealth.

Fessenden Transatlantic Telegraphy. — The experiments in wireless telegraphy which are to be carried out between Machrihanish Bay and Boston, under license from the Postmaster-General, will prove what the National Electric Signalling Company can do with the Fessenden system of wireless telegraphy. The preparations for the signalling station at Machrihanish are well in hand. We are informed that a tower 400ft. high and 3ft. in diameter, with cross spars on the top 56ft. long, is to be erected by the Brown Hoisting Machinery Company of New York. The base will be formed by a bed of concrete, while at a distance of 6ft. from the ground the tower will be fixed to the foundation. Insulated steel guys placed every 100ft. from the ground and fixed to foundations of concrete will keep the tower in position. Within the tower will be a stairway leading to the top, with balconies every 100ft. The material for the tower, etc., is at present on the way from America. It is expected that the station will be ready in three months. The tower on the American side is already completed. It is situated a little north of Boston. The National Electric Signalling Company hope, through the stations at Boston and Machrihanish, to set up an efficient service of communication between Great Britain and America, and to so perfect their system that messages sent by it cannot be tapped.

Central Technical College.—At a meeting of the council of the City and Guilds of London Institute held on Monday last, the diploma of "Associate of the City and Guilds Institute" was awarded to the following matriculated third-year students of the Central Technical College who have completed a full course of instruction as prescribed by the council : — Civil and mechanical engineering: C. J. Balding (Bramwell medal), R. W. Allen, C. M. Baissac, A. M. Beale, G. E. W. Bridge, R. W. Buttemer, F. C. Cooper, J. A. Denney, L. J. M. Guggenheim, G. W. Halse, C. Herbert, J. Hodgkinson, C. B. Job, L. King, S. Lacey, A. J. H. Laing, A. R. Mitchell, J. E. Montgomery, K. Newton, A. R. Reed, L. M. Regnard, G. M. Smith. Electrical engineering: W. H. Grinstead (Siemens medal and premium), A. J. Aldridge, C. R. Bland, E. B. Brown, J. L. Cook, P. G. Dani, P. Eisler, R. R. Elliott, O. Faber, W. M. Hooton, H. R. Hudson, G. Johnson, N. H. Martin, C. R. McGowan, C. E. Nightingale, H. K. B. Reed, F. C. Street, F. W. Strickland, K. J. Thomson, F. L. N. Tuck, W. Turner, A. Vipan, E. C. Webber. Chemistry: W. H. Eagle, F. J. Harris, W. J. Wilson. In addition to the above, certificates have been awarded to 32 matriculated third-year students who have completed a full course of instruction at the Central Technical College and to 68 students who have completed a full course of instruction at the Technical College, Finsbury.

Iron and Steel Institute.—The autumn meeting of he Iron and Steel Institute will be held at Sheffield on Tuesday, Wednesday, Thursday, and Friday, Sept. 26, 27, 28, and 29, 1905. Mr. R. A. Hadfield is the president of the institute. The Cutlers' Hall, Sheffield, will be used as the hon. secretaries' office, and the meetings will be held in the new university buildings. The following papers have been offered for reading: "On the Metallurgical Department of Sheffield University," by Prof. J. O. Arnold, Sheffield; "On the Thermal Transformation of Carbon Steels," by Prof. J O. Arnold and A. McWilliam, Sheffield; "On the Nature of Troostite," by Dr. Carl Benedicks, Upsala; "On the Occurrence of Copper, Cobalt, and Nickel in American Pig Irons," by Prof. E. D. Campbell, Ann Arbor, Michigan; "On Pipe in Steel Ingots," by J. E. Fletcher, Sheffield; "On Steel for Motorcar Construction,' by L. Guillet, Paris; "On the Presence of Greenish-coloured Markings in the Fractured Surface of Test Pieces," by Captain H. G. Howorth, R.A., Sheffield; "On Overheated Steel," by Arthur W. Richards, Grangetown, and J. E. Stead, F.R.S., member of council; "On Segregation in Steel Ingots," by B. Talbot, Middlesbrough; "On a Manipulator for Steel Bars," by Douglas Upton, Jarrow; "On Machinery for Breaking Pig Iron," by Cecil Walton, Whitehaven; "On the Influence of Carbon on Nickel and Iron," by George B. Waterhouse, New York. A large number of visits to works in the district have been arranged, and the social side of the programme has not been neglected.

Kieff Exhibition.—We are informed that the fourth congress of Russian electricians is to be held from April 2 to 15 next year at Kieff, under the authority of the Government. The meeting is organised by the Imperial Technical Society of Russia and by the town authorities of Kieff. The object of the meeting is to enable Russian electricians to meet together in order to discuss the actual state of the industry, and to witness trials of the most recent developments in electrical science. In order that this may be done, an electrical exhibition is being organised. This is to be opened on March 25, and will last for about three months. The exhibition will be divided into various departments, and special attention is to be paid to the application of electrical power to different industries and to agriculture. Apparatus connected with the application of electricity in medical science will form another department of the exhibition. The Minister of Finance has arranged that foreign exhibitors shall be able to send exhibits into Russia without payment of import duties, provided that the goods are returned within three months of the closing of the exhibition. The municipality of Kieff is making arrangements for a number of congresses during the time that the exhibition is open. These congresses will be devoted respectively to telegraph work, to electric traction, electrochemistry, and other special departments of electrical engineering. The position of the town is in the centre of the most successful industrial districts in Russia, so that the exhibition should command the support of those most in need of the latest applications of electrical engineering. We understand that all the dates given above are in the Russian style.

Marine Turbines.—At last week's meeting of the Institution of Naval Architects a paper was read by Mr. William Gray, in which a comparison was drawn between the performances of turbines and reciprocating engines in the Midland Railway Company's steamers for its Irish and Isle of Man services. The new fleet consists of four vessels, two being fitted with reciprocating engines and two with Parsons marine turbines. The results of the official trials, he said, threw some light on the relative economy of the two systems of propulsion at various speeds, and showed that from 14 knots to 20 knots the turbine was more economical. The maximum difference occurred between 19 and 20 knots, which was the working speed of the vessels on service. In regard to coal consumption, the turbine did 20·3 knots for the same amount of coal as the reciprocating engine had at 19·5 knots. A further economy in the turbine steamers was effected in the amount of oil used for lubrication. The logs showed that this amounted in both steamers to five gallons per single trip. Speaking generally, the performances of the turbine steamers had been greatly superior to those of the steamers fitted with reciprocating engines. It was not possible to make a quantitative analysis of the cost of upkeep, but so far the turbines had cost practically nothing, excepting the cost of repairs due to an accident, and they required very little attention compared with what was necessary in the very best running engines of the reciprocating type. There could be no doubt that one great benefit derived from the use of turbines was the elimination of the vibration inseparable from the use of reciprocating engines in Channel steamers.

The Pacific Cable.—An account relating to the working of the Pacific Cable Act, with the report of the chairman of the Pacific Cable Board, has been published as a House of Commons paper. The report shows that the numbers of messages and words transmitted during the year 1904 5 were approximately 177,968 and 2,056,953 respectively, of which 106,782 messages and 1,183,929 words were inter-colonial. The audited traffic figures for 1903·4 amounted to 176,824 messages and 2,097,897 words, of which 108,211 messages and 1,232,928 words were inter-colonial. The actual expenditure of the Board on the service of the cable during the 12 months ended March 31, 1905, amounted to £50,751. 11s. 2d., against £54,824. 19s. 8d. in the previous year. The total receipts amounted to £87,446. 10s. 8d. (including a special item of £5,118. 15s. on account of repair services rendered by the "Iris"), against £80,118. 13s. 3d. last year. The surplus on actual working was, therefore, £36,694. 19s. 6d. The Board, however, set aside £35,000 for the renewal fund, and they had also to provide a sum of £77,544. 18s. for interest and sinking fund. The sinking fund will extinguish in 50 years the entire capital expenditure. Adding these payments to the expenditure, the deficiency on the year's operations amounts to £75,849. 18s. 6d., against £87,751. 4s. 5d. in the previous year. This deficiency has to be made good by the contributing Governments. Although in the year 1904-5 the receipts were swelled by the earnings of the "Iris," an item which cannot be expected to recur, it is satisfactory to note that the deficiency to be met by the contributing Governments in the second year of the cable's working is less than the annuity due on account of capital.

Magnetisation by Direct and Alternating Currents.—In a contribution to a recent issue of the *Elektrotechnische Zeitschrift*, E. Gumlich and P. Rose consider the differences between magnetisation by direct and alternating currents respectively, and the reasons of the differences observed. The authors go very thoroughly into the matter, illustrating their experiments with the aid of some interesting diagrams. It must suffice here, however, to give their principal conclusion in brief. Up to a frequency of about 50 periods per second the magnetisability of dynamo sheet iron of 0·5mm. thickness by alternating current differed but slightly from that obtaining with direct current. The observed differences—which for higher inductions of B = 12,000 to 14,000 and upwards completely disappear—are attributable in part to eddy currents, while for the rest they would seem to be accounted for by a certain magnetic lag. The value obtained from the formula

$$\frac{W}{p} = A[\eta B^{1.6} + p f B^2]$$

for Steinmetz's coefficient η coincides within the limit of the errors of observation with the values for η resulting from the static tests. The fact, however, that the values for the eddy-current coefficient, f, up to about B = 12,000 decrease with increasing induction, favours the deduction that the second expression on the right of the equation, hitherto ascribed entirely to the consumption of energy through eddy currents, is due in some degree to hysteresis. The following formula

$$\frac{W}{p} = A\{\eta B^{1.6} + p [\epsilon (12{,}000 - B) B^{1.6} + f' B^2]\}$$

has proved useful to represent the total watt consumption through hysteresis and eddy-current losses, in which the expression containing the factor ϵ is to be taken into account only for inductions up to B = 12,000, and left out for higher values.

London County Council Trams.—The Highways Committee of the London County Council are by no means prepared to accept as final the decision of the House of Lords as to the running of tramways over the bridges and along the Embankment. The Parliamentary Committee of the Council have also a good deal to say on the matter, and emphasise the fact that the decision of the House of Lords in throwing out the Bill was arrived at without a due consideration of the proposed tramway extensions other than those discussed. The following extract shows the general trend of the committee's report: "We cannot express too strongly our feeling at this high-handed policy of the House of Lords. We feel that there is great reason for the public to resent the action of a majority of the Upper House in using parliamentary powers, which should only be exercised for the benefit of the public, to support individual views and interests, and we are not surprised to find that an outburst of indignation has been occasioned throughout London. The ill-considered action of the House is further illustrated by the fact that the Bill was rejected as a whole, although it contained the important proposals referred to below, none of which were apparently thought by the House to deserve a moment's consideration. These proposals were: the extension of time for some four miles of tramways authorised in 1900, the electrification of the authorised tramways over Vauxhall Bridge, the diversion of the tramway subway at the Embankment end, the extension of the authorised subway tramway from the Strand to the Embankment, the deviation *vid* Stondon Park of the Lewisham and Forest Hill tramway authorised last session, and a short new line from the Crystal Palace to the county boundary. We strongly advise the Council to reintroduce next session in its entirety the Bill which was rejected by the House of Lords on July 18, 1905, and to include therein such other schemes as the Council, on the recommendation of the Highways Committee, may think fit to sanction." It will be seen from the above that the House of Lords have, by their refusal to refer the Bill to committee, hung up tramway extensions which were distinctly not controversial in

Digitized by Google

character. The report of the Royal Commission on London Traffic should help the application next year for the facilities now refused.

Change of Pressure.—Mr. Sims Williams, barrister-at-law, last week held an inquiry on behalf of the Board of Trade into the proposed change of pressure in the supply of electricity to the consumers in the borough of St. Marylebone. Electricity was formerly supplied in the borough by the Metropolitan Electric Supply Company, but by the St. Marylebone Electric Lighting Act, 1901, the company sold their undertaking to the Borough Council for a sum fixed by arbitration at £1,212,000. Under the Act the Borough Council were to supply electricity by continuous current under a system to be approved by the Board of Trade. Up to the present time the Metropolitan Electric Supply Company has been supplying electricity partly by alternating and partly by continuous current, and with a considerable number of declared pressures. The Borough Council propose to supply at a pressure of 240 volts. Those consumers who were supplied before March, 1896, may, under the Board of Trade regulations, withhold their consent to a change of pressure, and have done so. The County Council have approved of the change on certain conditions. Mr. Arthur A. Wright, the consulting engineer to the Borough Council, gave evidence as to the benefits to be derived from the proposed change of system and increased pressure to 240 volts. He said that the proposed system would be more reliable and less dangerous than the present one, and would prove more economical in working. The objectors said that the change would entail great inconvenience and expense, besides an increased risk of fire, which might affect the validity of their insurance policies. It was also urged by the medical faculty in the borough that their electrical appliances were not adapted to the increased pressure. Mr. Sims Williams will forward his report and recommendations to the Board of Trade in due course, but we cannot doubt but that the change will be enforced. This is only right, as the Council have to pay for any alteration to consumers' wiring necessitated by the change.

Double-Filament Telephone Lamp.—Accompanying is an illustration of a double-filament lamp which has

been introduced by Messrs. Mix and Genest for use in telephone exchanges. An objection to the employment of incandescent electric lamps for telephone signalling purposes has been that the failure of a lamp cannot be at once detected, since but one control lamp is provided for each group of lamps. To ensure that a call signal attracts notice at the switchboard, notwithstanding the failure of a particular lamp, special control relays are now generally provided with resistance for inserting automatically in parallel with the lamps. These relays serve to switch in the lamp which controls a large number of call lamps, as soon as a call is made. But such an arrangement is subject to the disadvantage that the failure of a lamp can be immediately detected only when there is no second call at the moment. Moreover, the control lamps show that a lamp is defective, but do not indicate which—hence loss of time in testing, with consequent disturbance of the service. In order to avoid these objections the new lamp under notice has been designed. This lamp combines in itself the call and control signals. It is novel in that, instead of a separate resistance for switching in parallel, the lamp contains a second filament, which is not noticeable so long as the principal filament remains intact. The auxiliary filament is of higher resistance than the principal filament, and consequently has a longer life. Should the illuminating filament break, the auxiliary filament assumes a dull red glow, thus indicating the defect. The watt consumption of the lamp is the same as for the ordinary type of carbon-filament lamp, plus the loss in the auxiliary filament. Further details will be found in a recent issue of the *Elektrotechnische Zeitschrift*.

Electric Refrigerators.—Mr. J. C. Chamberlain contributes to the *Electrical Review* of New York an interesting article on the use of small automatic refrigerators driven by electric motors. We need hardly here recapitulate the advantages of mechanical refrigeration over the older methods employing ice as cooling agent. For large cold-storage schemes in this country mechanical refrigeration is always employed. It is rather to the author's schemes for small plants for small hotel and domestic purposes that attention should be drawn. For such work, plants requiring from 2 h.p. to 15 h.p. to drive can be conveniently installed and worked by electrical energy from the public mains. With automatic regulation the cost of supervision, which has hitherto largely prevented the use of such small plants, can be eliminated, and there is no more difficulty in introducing this automatic control than in other cases of electrical driving. The author gives a table to show that with ice at 15s. a ton a small plant driven by a 2-h.p. motor will save its own cost in under five years if the ice required per day in the summer now amounts to 1,700lb. The cost for electrical energy in order to do this is taken at 1½d. per unit, which is reasonable in view of the special character of the load. Thus the refrigerating load demand is the exact reverse of a lighting load, not only during the months of the year, but during the hours of each day. It is a summer load, and very desirable because the lighting requirements are then comparatively small. It is a long load in the summer months, when the operation of automatic refrigerating plants will average 16 to 20 hours each day. The duration of daily load will, of course, follow the weather conditions from the summer to the winter months. It is a day load at any time of the year, being continuous during the daytime, when the cooled supplies in refrigerating boxes are being removed and replaced by new supplies to be cooled. Electrical engineers in this country responsible for central-station working will fully appreciate the advantages of such a load, and we know of one or two instances in which breweries have been supplied with power at considerably lower rates than 1½d. per unit on the understanding that the power in question was used for refrigeration purposes. With the increase in the size of the plant the advantages in favour of the mechanical refrigerator go up rapidly, as is shown by the author's tables.

Tramway Experts.—The city of Birmingham is favoured by the large number of tramway experts amongst its citizens, and by the free way in which these place their

Digitized by Google

knowledge at the disposal of the community. In the first place, the Corporation have secured as their tramway manager Mr. Alfred Baker, and under his advice the passing of the horse and steam trams has been expedited. That the trolley system has been adopted has offended the City Association, and the executive committee of this association has issued a final report condemning the system. The status of the members of this committee is not disclosed, but their report shows how fit they are to condemn the trolley. "Having drawn attention to the large number of fatal and other accidents which have recently happened on tramways using the overhead system, the committee point out that they were thankful to the Lord Mayor (Alderman C. G. Beale) for the assurance given seven months ago that the mode of traction was not yet determined for Birmingham. They are now astonished to find that in spite of that assurance the Tramways Committee is 'hurrying forward the laying of as many routes as possible upon the overhead trolley system without any genuine attempt to inquire into other systems of traction which are really safe and equally convenient.' Having given a great deal of time to the question, the committee express the conviction that some of the surface-contact systems which are being adopted in other English towns are vastly superior to, and, they believe, as cheap to work as the overhead trolley system. Moreover, they are certain that within a very short space of time motor omnibuses should be so perfected as to become the best and cheapest form of traction for many routes. The only reason for the adoption of the trolley seems to them to be the false one of economy on the ground that it is the cheapest system to lay down. But if economy without efficiency is to be the ideal for Birmingham, they hold that the horse and steam trams should be retained, as the capital expenditure on the overhead system is about 50 per cent. more than either. Further, they state, notwithstanding Mr. Alfred Baker's remarks to the contrary, that motor omnibuses require much less capital outlay, and are as cheap or cheaper to run." The Birmingham tramways have already been the field for experiments, as for years there have been four distinct systems of driving employed—*ie*, the trolley, accumulator traction, steam trams, and horse cars. The financial returns from them were available to the above committee, and we are somewhat surprised that any uncertainty should still exist as to the best system. Still, it is useless to be an expert or a committee of experts if you do not differ from the standard practice whenever possible.

Wireless Telegraphy.—The information given in a return on this subject asked for by the House of Commons deals firstly with the working arrangement between the Marconi Company and the General Post Office for the transmission of messages to ships at sea. This arrangement was in active operation from Jan. 1 last to March 31. During that time 111 messages were handed in at post offices to be transmitted to ships at sea. Of these, as far as the records of the Post Office show, 21 failed to be delivered. In 16 of these instances a refund was applied for, and in six cases refund was not granted because the Marconi Company declined to entertain the application on the ground that the telegram had been accepted, at the sender's risk, after the hour shown in the company's sailing list as the latest at which such a telegram should be sent. During the same time no less than 1,655 messages were received from ships at sea and telegraphed to the general public over the Post Office wires. The returns as to the number of licenses which have been applied for under the Wireless Telegraph Act of 1904, show not only the applications, but which have been granted and which refused. We were surprised to see that no less than 73 licenses had been applied for, but the majority of these are for experimental work. In practically every case where the experimental work is such that it would not interfere with commercial systems the license has been granted. In consequence of this we find that every system which has been brought to public notice has been granted one or more licenses, which will allow of further developments being made towards commercial working. For Transatlantic signalling the following applications have been made. The Anglo-American Telegraph Company wish to carry out trials between North America and Valentia, in Ireland; the system to be used is not disclosed, and the Postmaster-General has the license under consideration. The De Forest Wireless Telegraph Company have been offered a license which would enable them to work a signalling station in the Hebrides, or on the West Coast of Scotland, for communication with America; this would also be experimental in the first instance. The company's application for other licenses for commercial ship to shore communication has not been granted in regard to the majority of the localities indicated, on the ground that there would be risk of interference with other stations. They have, however, been offered a license for sites in certain specified localities. Their application for providing inland communication for Press purposes between London, Manchester, Liverpool, Glasgow, and Belfast has not been granted yet, as further information is required by the Postmaster-General respecting the same. The Marconi Company have applied for a number of licenses for commercial working, both on their own account and in connection with Lloyd's. A license is in preparation which will enable the company to establish commercial communication with America and with ships at considerable distance from Poldhu, in Cornwall. The same applies to their application for commercial communication with ships at comparatively short distances from a large number of signalling stations. A license is being executed in favour of the National Electric Signalling Company, who will experiment with Transatlantic signalling from Machrihanish Bay with the Fessenden system. It will be seen, therefore, that a good deal of work is likely to be undertaken by various companies for long-distance signalling which should prove not only the commercial feasibility of any one installation, but also the question of whether the sending of messages across the Atlantic can be simultaneously undertaken by several signalling stations at once. It will also be seen whether the large amount of energy required for sending these messages can be discharged without interfering with short-distance equipments round the coast. The Armstrong-Orling system is to be used partly for experimental purposes and partly for private business between Ballinasloe and Taughmaconnel, a distance of 50 miles. The Lodge-Muirhead system has been refused commercial application from Dover, the Isle of Wight, the Lizard, and Fastnet, on the ground of risk of interference with other stations, but a license is offered for sites in other districts. An application for a license is under consideration from the Midland Railway Company for the use of this system from Heysham and the company's steamers. The general conclusion to be drawn from the return is that a very large number of people are experimenting with wireless telegraphy, and that the Postmaster-General is not using the Wireless Telegraph Act to prevent research work. It seems, however, that until the non-interference of competing systems has been established, he is not prepared to grant licenses for two companies to work in the same area.

THE CALCUTTA ELECTRIC TRAMWAYS SYSTEM.

Due to more immediate interests nearer home, it was not until a few years ago that attention was directed to the possibilities of lucrative tramway undertakings in the East. Electric traction has infused new life into systems which formerly employed steam and animal traction, and the success of such conversions has been followed by numerous concessions for electric tramways in places such as Hong-Kong, Singapore, Manilla, Rangoon, Mandalay, Tokio, Batavia, Penang, Colombo, and others. The largest and most important of the tramway systems in the East is that of Calcutta, and is of more than usual interest, having regard to the conditions under which it operates. It is hardly necessary to say that Calcutta, the metropolis of India and the seat of Government, is one of the largest and most important cities of the East. It is a very large port, and the centre of the extensive Indian trade in tea, jute, and general produce and merchandise. On account of its low-lying position, an extensive system of artificial drainage has been adopted, and, though fairly well carried out, is not nearly sufficient to cope with the extraordinary downpours during the rainy season, which flood the streets in certain sections of the city for the greater part of the day, sometimes to a depth of about 2ft. and upwards. Another climatic condition which causes great damage and difficulty from a traffic point of view is the number of severe wind-storms, approximating to cyclones, which sweep over the city at the beginning and the close of the rainy season (which lasts from the middle of June to the end of September), often with destructive effects, uprooting trees, unroofing houses, and causing general damage.

Calcutta is divided into three natural parts: the European business district, practically confined to an area of 250 acres, located in the west central portion of the city, bordering on the eastern bank of the River Hooghly; the native residential and business district, located in the northern part; and the European residential district, located in the southern portion of the city. The total population, with certain adjoining suburbs, is about 1,000,000, which does not include the municipality of Howrah, located on the opposite side of the Hooghly river, having a population of 157,594, nor two other suburbs which will soon come within the tramway zone, and which have an additional population of 51,806. The total population can thus be put down at 1¼ million. In the native town, the streets, as in all Oriental cities, are narrow, and lined for the most part with unprepossessing houses and huts, which are very densely peopled, one ward having a density of 281 per acre, or 180,000 per square mile. Broad roads are, however, now being cut through the native quarters, and the congested districts, which have up till lately been the hot-bed of epidemics and plague, are being opened out, and this work is the beginning of a large improvement scheme upon which the Government has entered. The southern European residential portion is traversed by wide and well-paved roads, which are lined with very commodious and roomy houses, inhabited for the most part by Europeans. The European community does not differ essentially in composition from that of other large cities of the East (where there is an almost entire absence of the European artisan). The official element is very strong, and the professions in general are well represented, while there is a larger number of European merchants. The total number of Europeans and allied races resident in Calcutta during the cold weather is approximately 14,000.

The tramway company was registered in England on Dec. 23, 1880, and operated its system by steam trains on the Kidderpore section, and horse cars on the remaining section, until 1901, when the original concession expired. In 1899 an agreement was entered into with the Corporation whereby the company was granted a new concession for 30 years from Jan. 1, 1901, in consideration of the company converting the system from horse to electric traction within three years. The capital authorised is £700,000 in £5 ordinary shares, all of which have been issued, in addition to which there is a 4½ per cent. debenture issue of £350,000. The company's head office is 1, Queen Victoria-street, London, and in Calcutta its representative is Mr. Martyn Wells, managing agent, Mr. A. J. J. Pfeiffer being assistant manager and chief engineer.

The electrification of the tramway system was carried out according to the most modern plans in everything as regards central-station equipment, overhead and underground conductors, rolling-stock, etc., and especial attention in design was given to adopt the plant to the peculiarities of tropical and local conditions. The engineers and contractors were Messrs. Dick, Kerr, and Co., of London and Preston, for all work except the buildings and the reconstruction of the permanent way, which was carried out by the company itself. All the rails, ironwork, bonds, etc., for the permanent-way work were, however, furnished by Messrs. Dick, Kerr, and Co. The entire conversion was creditably carried through in a comparatively short time, and the various parts of the plant have since then worked well under the most trying conditions. It is very gratifying to note that throughout the whole period of conversion from horse to electric traction both the company's officials and the contractors received the greatest help and encouragement from the various Government and local authorities.

Present Routes.—As in all Oriental cities, the streets are narrow, especially in the native quarter, and as the bulk of the riding public are natives, the authorities very wisely sanctioned the laying of lines in the main native thoroughfares, although these are much narrower than ordinarily found in large cities of the West, but hardly more so than in some of the smaller old towns of Europe. The Chitpore-road, which forms one of two main arteries of the native section, is probably unique as regards density of traffic, including foot-passengers, carriages, and carts, besides the electric cars, but even with this dense traffic the Western visitor is astonished to see how well and efficiently the tram service is kept up. The tracks in all narrow streets are laid as much to the side as is possible, and the distance, in many cases, from the nearest rail to the kerb does not exceed 2ft. This is necessary in order to give sufficient clearance on the other side of the tracks to accommodate at least one vehicle. As remarked above in the description of Calcutta, the entire area of the city is flat. There are no grades to speak of, except when crossing three bridges, the approaches to which do not exceed 150 200 yards, the grades being not more than 4 per cent.

The present tramway routes, covering a total length of 23 route miles double track throughout, all radiate from one small section of the city, where the majority of the Government offices and European business houses are located, in the west central portion bordering on the river. This small district is the objective point of thousands of natives from all directions in and about Calcutta, who have business in the courts and numerous offices. The cars on the various lines are run to either one of two termini, one being at the loop near the High Court (Fig. 1); the second the Esplanade Junction, at the intersection of Dhurrumtollah-street with Chowringee-road, the latter forming the junction between the northern and southern lines. The number of cars at these two points is during the rush hours very large, trains following one another in close proximity. The number of trains arriving at these points per day amounts on an average to: High Court, 750; Esplanade Junction, 1,150. The northern section of the city is served by three routes, the central portion by three, and the southern portion (including suburbs) by two, all double-tracked. A few years ago a fine large road (the Harrison-road) running east and west was cut through from Sealdah railway station to the bank of the river at the Floating Bridge (Fig. 2), which now forms the main artery of the cross city traffic in the native district. A double line of traffic has just been laid down the centre of the road, and will shortly be opened for traffic. There are eight main routes, and these, with two exceptions, can be considered city lines. The Chowringhee line runs southward to a densely-populated suburb, Bhowanipore, touching upon the way the western extremity of the European residential zone. On this route is also located a famous Hindoo temple, which attracts a constant native traffic throughout the year, and during certain holy festivals the

Digitized by Google

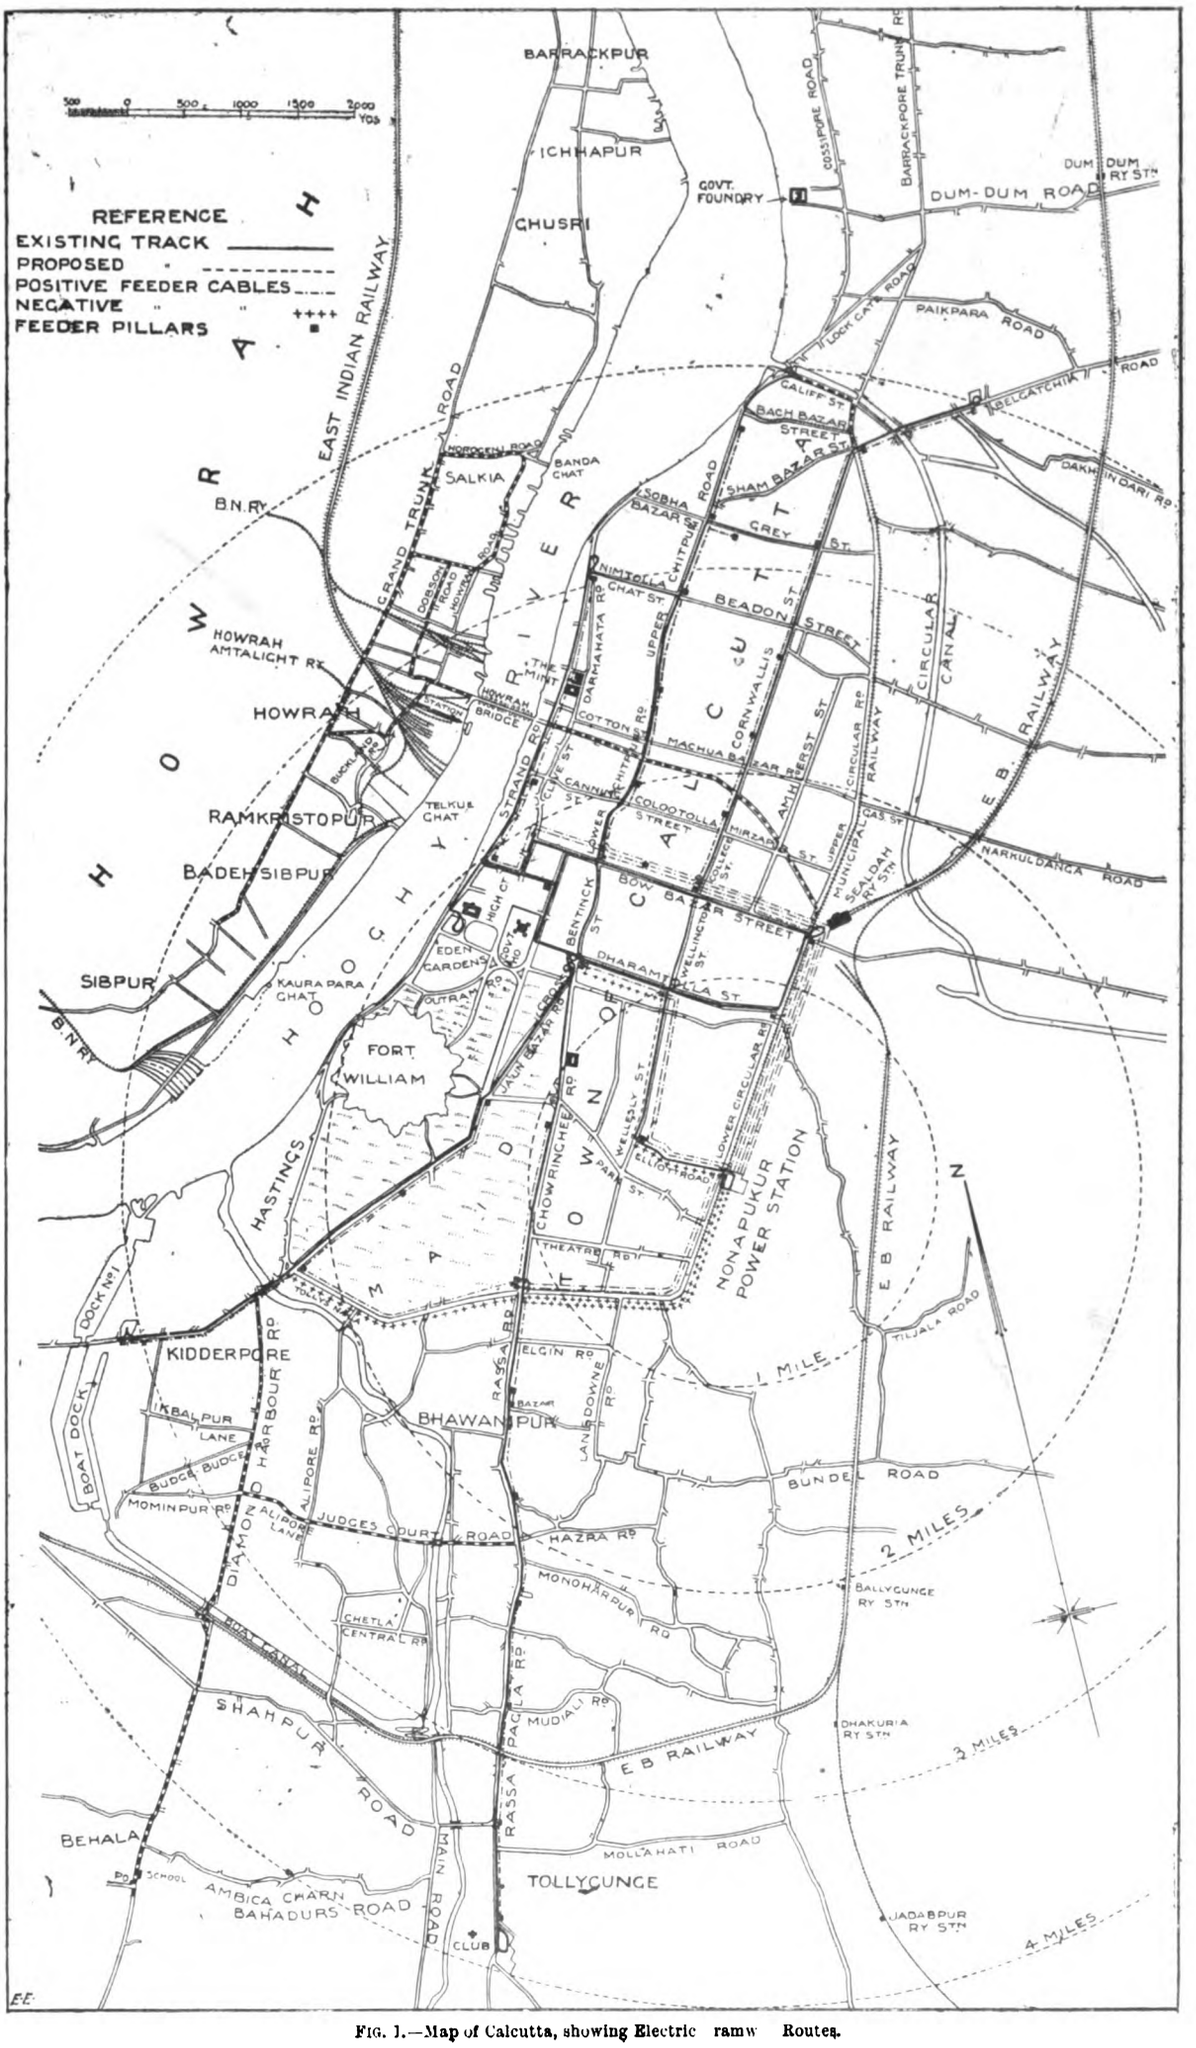

FIG. 1.—Map of Calcutta, showing Electric ramw Routes.

Digitized by Google

service has to be doubled to cope with the rush. The line to Kidderpore feeds the populated suburb which lies to the south, near the river, caters to the large traffic between the extensive docks and Calcutta, and derives a large traffic from the race meets which are held on the racecourse on the Maidan.

The total route mileage (all double track) at present is 24·75, with Harrison-road included. On the basis of a tributary population of approximately 800,000, the route mileage per 1,000 people would be ·031, as against about ·08 found in England and an average of about ·25 to ·30 found in the United States of America in cities of about one-third population of Calcutta. The low mileage *per capita* is due to the congested condition of the native quarters, which cover not nearly the area of an equally populated Western city.

Traffic.—All tramways in India, which likewise holds good for the East in general, have, of course, mainly to depend upon the natives for their earnings, since Europeans form but a very small part of the population, and in investigating the possible establishment of a system, due weight must be given to their characteristics, habits, average income, and occupations. In Calcutta the average income of the native working-man and labourer is not sufficient to permit him to ride freely, and in consequence he is but a small factor in the earning powers of a tramway, the main fundamental revenue being derived from the business and professional classes and Government employés. The native is a great litigant, and will spend any amount of money and time over the smallest case, and in consequence of this characteristic the courts located in various parts of the city employ a great many clerks and other officers, and daily attract a large number of people, the major part of who use the tramway. Another class of rider is the clerk in European business houses and Government offices which are located in the well-defined districts mentioned above. Native traders do considerable business among themselves in distinct parts of the city, in what are called bazars, which afford constant interchange of traffic. All the above constitute the steady riding factor, or regular traffic with two "rush" points per day, on which the tramways may depend. The "floating" traffic, which is by no means small, is created mainly by the temples of the Hindoos or mosques of the Mohammedans, which constantly attract extensive crowds for worship, but which on many days, especially on those which are holy or sacred, form the objective points of many thousands of devotees from the city as well as the surrounding districts. This religious feature is a valuable asset in the earnings of all Eastern tramways, provided always that these objective points are sufficiently far removed from the centre of the native population to induce them to ride rather than walk.

The first line under electric traction in Calcutta was open for regular service on March 27, 1902, and the entire

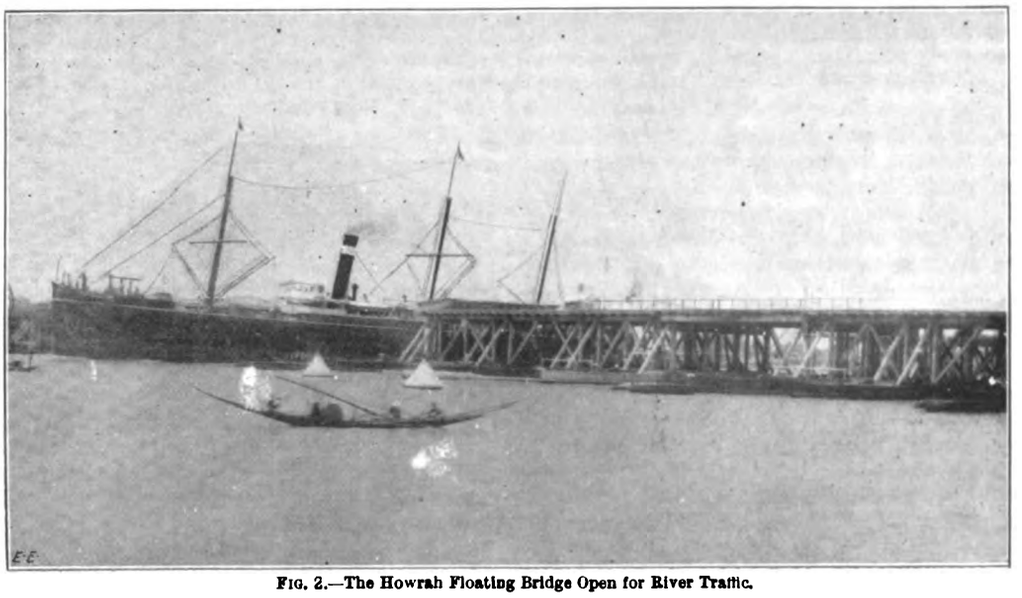

FIG. 2.—The Howrah Floating Bridge Open for River Traffic.

FIG. 3.—Dalhousie Square, showing Side-Pole Construction.

Digitized by Google

system was operated electrically on Nov. 20, 1902. An exceptionally large increase of traffic immediately followed the opening of each section, which, however, was to be expected, since, under the steam and horse traction, there was only one class for passengers, and due to the severe climatic conditions of excessive heat and humidity prevalent in Calcutta during the summer months, and the consequent exhaustion of the horses, even this second-class service was not nearly sufficient to cater efficiently to the riding public. The total traffic revenue increase with electric traction over that of horse traction after two years of operation is about 75 per cent. This increase is due not only to more accommodation furnished in the shape of extra car mileage for the second-class passengers, but because the motorcars which serve the first class developed an altogether new source of revenue, since people are now riding who in past years never made use of the tramway, and especially is this the case with European and the better class of natives.

FIG. 4.—Strand Road, Calcutta, at the intersection of the approach to Howrah Bridge.

The car service, or rather train service, regulated carefully according to requirements, begins at 5 a.m. and ends at 10.30 p.m. The native being an early riser, traffic begins quite briskly in the morning, takes a sudden rise at 9.30 to 11 a.m. during the office traffic, falls off during the afternoon, increases rapidly again at 4.30 for the return office traffic, and is practically finished at 9.30 in the evening, since the native travels about but very little at night. The maximum number of trains operated at one time during an ordinary weekday on the present 46 miles of single track is 132, this being increased to 145 on race days, and during the recent Pujah festival of the Hindoos (corresponding to our Christmas in importance) the then full equipment of 151 trains was required, the traffic to the temple at Kalighat from all parts of the city being very large. Although there are well-recognised fixed stopping places on the system, it has not been found practicable to make use of them exclusively on account of the very severe conditions of heat and rain, which make it necessary for the comfort of passengers to set them down and pick them up wherever they may require.

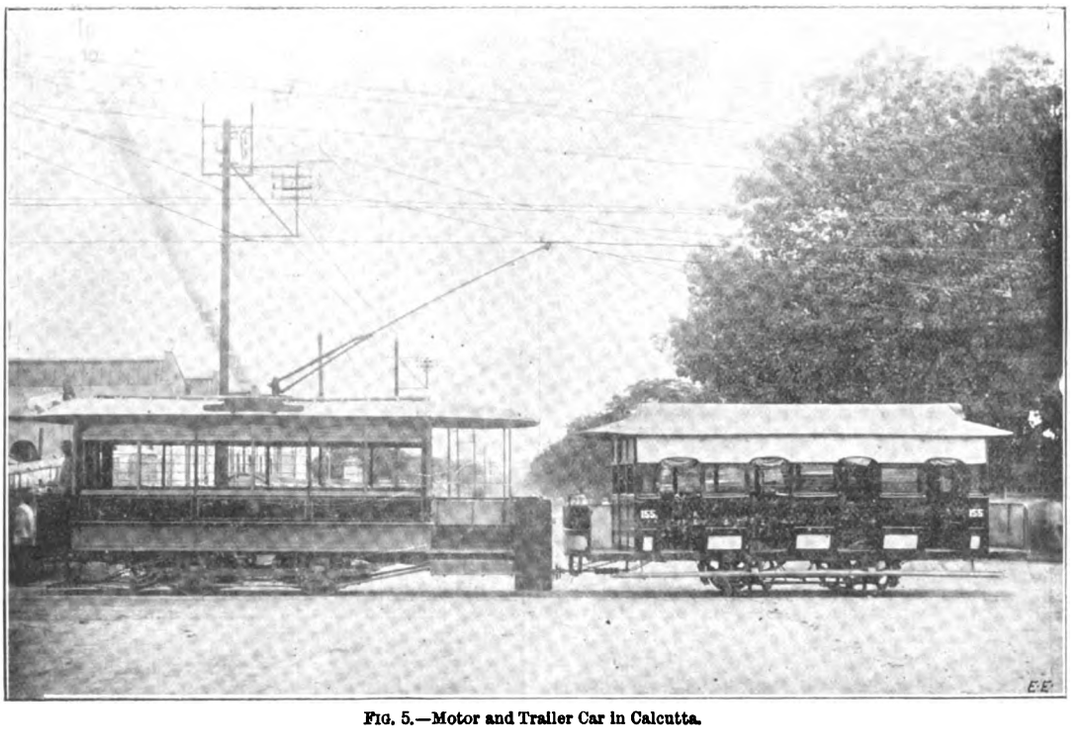

FIG. 5.—Motor and Trailer Car in Calcutta.

The traffic staff is all native, with the exception of the superintendent and his two first assistants, who are Europeans. A considerable number are traffic employés from the old horse-car days, and in consequence had the experience which made their initiation into electrical traction comparatively easy. Drivers of old horse cars were taken on to act as motormen, and right from the start acquitted themselves admirably, it being really

Digitized by Google

astonishing to note with what skill and coolness they handle a heavy train in the narrow streets, full of people and vehicular traffic and native conveyances. Conductors are checked and supervised very carefully by a comparatively large staff of checkers and inspectors, who are promoted from the ranks of conductors.

A few traffic results are herewith given which might be of interest to show how they compare with those found in the West: total number of passengers carried per year, 21,000,000; total yearly train miles run, 3,300,000; passengers per train mile, 6·4; average distance travelled per passenger, 2 to 2¾ miles; average fare per passenger, 1·46d.; traffic operating expense per train mile, 1·25d. The operating expenditure per train mile, as noted, is about 1·25d., which includes salaries and expenses for the superintendent, assistants, motormen and conductors, regulators, starters, cashiers, etc. This is about 40 per cent. of the results in England, and 30 per cent. of those in the States.

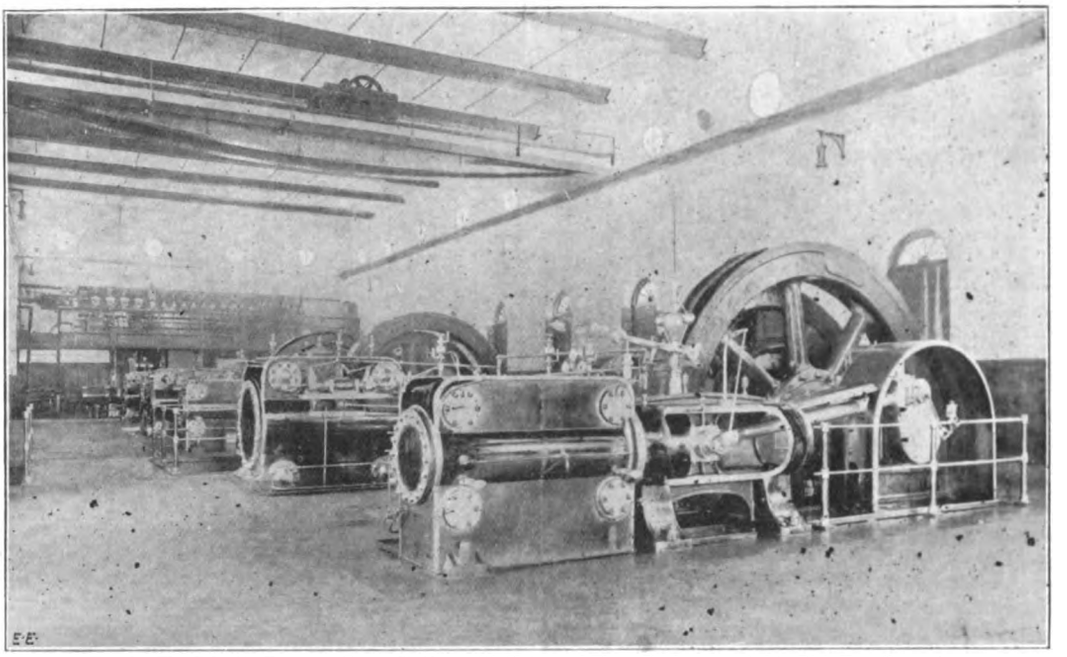

FIG. 6.—The Calcutta Tramway Power Station, with Yates and Thom Engines coupled to Dick-Kerr Generators.

Permanent Way.—A considerable portion of the track in the early days of the company was single with turn-outs. This was found to be very unsatisfactory, especially in an Eastern city where an accurate schedule timing, such as is required to give a satisfactory service with single track and turn-outs, was practically impossible. The track was gradually doubled throughout, the last line being the Kidderpore section, just before the introduction of electric traction. Some of the reconstruction was started as far back as 1892, but the bulk of it was completed three or four years ago. The gauge of the track is the standard

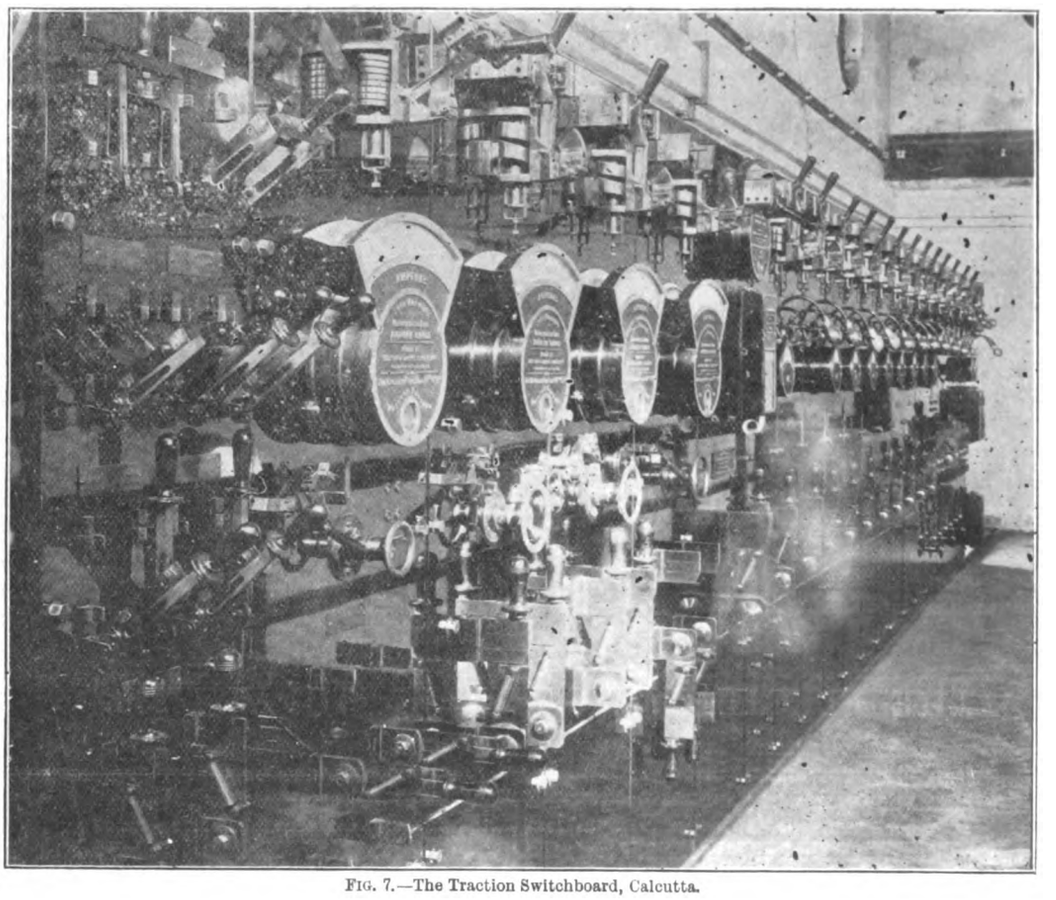

FIG. 7.—The Traction Switchboard, Calcutta.

Digitized by Google

4ft. 8½in. Girder rail was substituted for the old box rail throughout, the rail on some of the sections which were first reconstructed being 95lb. per yard with ¾in. and ⅞in. groove, but all the later types, and those which are now being used on extension work, consist of a 101lb. rail with 1⅛in. groove. In spite of the heavy traffic to which some of the lines are subject, the track has stood well, and where it has given way it has probably been due to the sinking of the subsoil. The usual tie-bar construction is employed, five bars being provided on an average per rail length of 30ft., each bar weighing 15¼lb., including check-nuts and bolts. The rail is embedded on a lime concrete stringer, having a width of 16in. and a depth of 9in. This concrete is made up of ten parts broken brick, three parts of ground brick, and two parts of slaked lime. The above method of making-up concrete is prevalent in Calcutta, since broken stone is expensive, as is likewise good sharp sand, and the high price of Portland cement prohibits its use in this connection. The lime concrete, with the above composition and material, makes a very good substitute for the ordinary cement concrete, though more care is required to consolidate it, and a greater time is necessary to enable it to set properly. The edges of the rails on all lines in the city are paved to a width of 18in. on the outside of the double-track rails and 9in. on the inside, Indian granite setts being used. In some streets, and parts of streets where the track is specially heavy, paving is carried straight across the double track to a width of 18in. on the outside of the extreme rails. The setts are embedded in sand, and grouted with four parts of river sand and one of Portland cement. In its agreement with the Corporation, the company undertakes to keep the roadway in proper repair to within 18in. on the outside of the extreme rails. Two No. 4/0 B. & S. Neptune bonds are used for every joint, the bonds spanning the fishplate, and having a length of 2ft. 6in. The track is adequately cross-bonded.

Overhead Line.—This system is worked throughout by means of the overhead trolley, and on account of the peculiar conditions existing, a part of the lines had to be equipped for the side-running type. Of the 23 miles of route, 20 per cent. is centre-pole construction, 30 per cent. is side-bracket construction, and 50 per cent. is span-wire construction. The poles used are made up of steel tubes varying in thickness and weight according to the requirements of their location. Each is built up of three sections, socketed into each other, giving the general appearance of a gradual taper. The average distance between the poles varies from 100ft. to 110ft. on the straight. All the poles are 27ft. 6in. high; the light poles weigh 673lb. and the heavy poles weigh 1,032lb. each. The brackets used on the side-running portions vary in length from 3ft. for centre-pole to 15ft. side-pole construction, the internal diameter of the tubes being 2in.

The trolley wire is of hard-drawn copper of 3/0 S.W.G. gauge, and is generally supported by double insulating hangers of the rigid suspension type, but flexible suspension has been substituted for these on that section of the Chowringhee lines where the speed attained is greater than the average, so as to lessen the effect of the blow on the cars. A similar improvement will be made on the Kidderpur line. The angle of the trolley pole varies considerably on the different side-running sections, the maximum outreach, which is on the Chowringhee line, being 4ft.

Feeder and Return Distribution.—The general arrangement of the feeder system, both positive and negative, is shown on Fig. 1, from which can be seen that the majority of the feeding cables are led to the central point of the city, where all lines converge. There are nine positive feeder cables, varying in cross-section from ·19 to ·6215 square inch, which emanate from the power-house and connected to 43 feeder and section pillars distributed over the various routes. The return or negative cables are three in number, one of them having a cross-section of ·7942 square inch and the other two ·3 square inch each. These are connected to points of the track, as shown on the map.

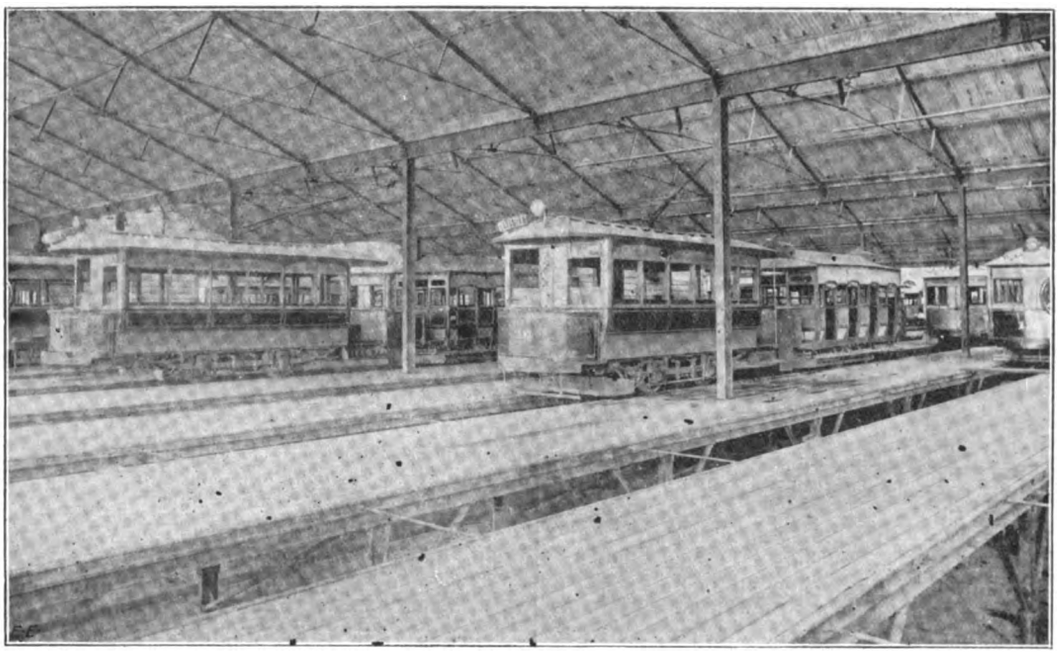

FIG. 8.—The Nonapukur Car Shed, showing the Raised Rails, which allow ready access to inspect the motors.

All cables are paper-insulated and protected by heavy lead sheaths, and were laid underground in cast-iron troughs on the solid system, the troughs as a rule being located along the outside margin of the tramway right-of-way. The cables are supported in the troughs by wooden bridges, and the whole trough is filled in with a special pitch compound. The troughs themselves are laid in a trench varying from 16in. to 24in. in depth, according to the nature of the ground. This system of laying has given rise to difficulties due to the cast-iron covers of the troughs being too thin and easily pierced by the picks of excavators. Several burn-outs of cables have been traced to this cause, and to obviate and eliminate this danger as much as possible, in all future cablelaying earthenware troughs are now being used with covers 1¼in. thick. It has been found that this thickness will withstand ordinary negligence in the digging up of the roadway. In order to forestall any difficulties which might arise due to the sinking of the soil, these earthenware troughs, especially in cases when they will carry high-tension cables in connection with the plant extensions, are embedded on a concrete stringer 6in. thick. The cables used for connecting from the feeder pillars to the trolley wires are $^{61}/_{17}$ S.W.G. rubber insulated, heavily braided, and lead covered. The feeder pillars themselves are made up of a cast-iron box, which is raised 2ft. from the ground in those places where there is danger of the pillar being flooded due to the rains. Each pillar contains

Digitized by Google

the usual standard switches and connections mounted on a marble or slate switchboard.

Rolling-Stock.—When converting from horse to electric traction, it was decided to adopt the train system, consisting of one motor and one trailer car, the former serving first-class passengers represented by Europeans and well-to-do natives who previously never made use of the tramways, and the latter providing accommodation for the old patrons. This system made it necessary to construct loops or triangles at various points of the lines for the turning of the trains. At present there are 171 single-deck motorcars, of which 96 are of the open type and 75 of the closed type. The motorcar bodies and equipments were made at the Preston works of Messrs. Dick, Kerr, and Co., and the trucks were furnished by Messrs. J. G. Brill and Co.

The car bodies (Fig. 5) are of plain strong construction, made to suit the climatic conditions, teak wood being used throughout, as being impervious to the ravages of white ants. The closed cars have a total seating capacity of 70. The open-type cars, which have a seating capacity of 40 passengers, are single-ended with the entrance from one side only, this being dictated by the loop system that was adopted.

The electrical equipment for each car, as manufactured by Messrs. Dick, Kerr, and Co., consists of two motors with one controller and all accessories. Each motor has a normal output of 25 h.p. under the standard rating. It might be pointed out that the motors have had to stand very severe operating conditions due to the heavy rains, which during the rainy season flood certain parts of the city to a depth of several feet, as already mentioned above. Heavy showers come on so rapidly, that the drainage system is incapable of satisfactorily coping with excess of water, which makes it difficult at times to get the cars out of the low-lying districts, which flood in remarkable short space of time.

Power Station.—The situation of the power station with respect to the tramway system can be seen on Fig. 1, and the general lay-out of the station plant on Fig. 6. The building is a brick structure, covered on the outside and inside with sand plaster, the usual form of building construction prevalent in India. The chimney is constructed of brick, and has a height of 150ft., inside diameter at top 7ft. 6in., and the base of the chimney is 36ft. square.

The equipment of the engine-room at present consists of three main engine-dynamo units of the same design, in addition to which there is a supplementary unit of smaller capacity, suitable for supplying current during the hours when the traffic is light, and likewise in working in conjunction with two of the large units to carry the maximum load in the station, thus leaving one large unit in reserve. The three large engines are of the horizontal cross compound condensing type, with dynamo and flywheel located between the high and low pressure sides of the engine. They are of the Yates and Thom type, and run at 90 revolutions per minute with a working pressure of 120lb. per square inch, and under these conditions the engines develop at their most economical operating point about 675 i.h.p. They are, however, capable of working satisfactorily up to 950 i.h.p., representing 25 per cent. overload. The cylinders are 21in. and 40in. in diameter, with a stroke of 3ft. 6in. The valve gear for working the admission valves is a well-tried release or trip gear of the improved "Dobson" type, consisting of hardened-steel catch plates attached to blocks which are connected by links to the steam valve levers, and have also spindles or rams coupled to the dash-pot pistons. The governor is of the quick-speed type with centre weight and cross arms, designed so as to give the necessary sensitiveness, combined with ample power to overcome the resistance of the tripper gear. A sensitive knock-off appliance is fitted to the governor arranged to disconnect the trippers and hold them in such a position as to prevent steam being admitted to the cylinders, in case the ergine should attain an excessive speed, or an accident happening to the governing gear. The flywheel is about 16½ft. diameter, constructed in sections, and has a weight of about 29 tons. The smaller engine is of the Robb-Armstrong automatic cut-off tandem compound side-crank D.C. type. The indicated horse-power is 250, with 135lb. initial pressure when cutting off at about one-third stroke in high-pressure cylinder at 200 revolutions per minute.

Each of the three large generators constituting part of the main unit is a standard direct-coupled continuous-current railway generator, as manufactured by Messrs. Dick, Kerr, and Co. The normal output of each of these generators is 500 kw., the normal current load rating being that with a working E.M.F. of 550 volts at the terminals of the machine. Each of these generators can safely carry 25 per cent. overload for an hour without injurious heating. The efficiency of each generator is about 95 per cent. full load and about 93¾ per cent. half load. The generator which is coupled to the smaller engine unit has a capacity of 150 kw., and is direct coupled to the engine, the general arrangement and mechanical and electrical features of this machine being practically the same as those for the larger units.

The switchboard is of the panel type, constructed of enamelled slate and supported by an iron framework, the whole placed on a gallery at one end of the engine-room and overlooking the same. The board consists of four generator panels, one main output panel, ten feeder panels, one lighting panel, one motor panel, three negative booster panels, and one Board of Trade panel. The general arrangement is shown in Fig. 7. For assisting the rail-return distribution, so as to comply with the regulations, which are that no part of the track return should show a greater drop than seven volts, three boosters have been installed, connected to the track by insulated return cables. These boosters have a respective capacity of 800 amperes at 80 volts, 300 amperes at 120 volts, and 300 amperes at 70 volts. The engine-room is spanned with the usual overhead crane, designed to lift 15 tons, the manipulation being accomplished by hand.

In the boiler-room there are at present six boilers of the Galloway (Lancashire) type, 30ft. long by 8ft. in diameter, the interior consisting of two furnaces joined into one Galloway flue, the furnaces being 3ft. 3in. in diameter, solid welded longitudinally and flanged transversely. To the present plant has just been added one Babcock and Wilcox boiler, which will not only help out the present installation, but will form part of the large extensions to the entire plant, which will be touched upon below. There are three Weir's patent direct-acting feed pumps, each having ample capacity to supply water for four of the boilers, thus leaving one in reserve for the present nominal output of the power-house. The pumps are 7in. in diameter by 9½in. steam-cylinder, and have a stroke of 18in. Each pump is capable of delivering 30,000lb. of water per hour. Ample cold storage is provided by bunkers immediately opposite the boiler fronts, it being possible to store sufficient coal to operate the plant for four weeks. In connection with the boiler plant a Green's economiser, consisting of 480 tubes, is provided.

The condensing plant is located in the basement of the engine-room, and consists of a surface condenser of sufficient capacity to deal with the exhaust from all three main engines, together with two steam-driven air-pumps (each having a capacity of two units), and two electrically-driven centrifugal circulating pumps, each pump being capable of discharging 72,000 gallons of water per hour through the condensers, and up to the water inlet on the cooling towers. The pumps are mounted on a self-contained bed-plate, with a 35-h.p. motor coupled direct. This plant, in conjunction with the cooling towers described below, is calculated for condensing 36,000lb. of exhaust steam per hour. When this amount of steam is being condensed, and the pumps are working at full speed, a vacuum of about 21in. to 22in. is obtained in the condenser during the cold season, when the atmosphere is dry. During the rains, however, the humidity in the atmosphere is large, and, in consequence, the efficiency of the cooling towers is very much reduced, making it possible to attain a vacuum of only 18in to 19in. with maximum load in the station. At present there are two towers with fan draught installed for the purpose of cooling the water from the condensers, one being of Klein's patent type, the other, which was recently installed, being of the Zschocke type. Both are rectangular towers 23ft. by 20ft. by 40ft. high, divided into two sections.

Digitized by Google

Four car-sheds, located at various extremities of the system, have been provided to house the present rolling-stock. The principal shed is that at Nonapookur, located on the same premises as the power station. Adjoining the sheds are the workshops, smithy, foundry, paint and wood-working shops, armature-winding department, etc., and it is here that all extensive repairs to car bodies, trucks, and equipments are carried out, the other three sheds attending to small petty repairs to controllers, lights, and miscellaneous equipments. The Nonapukur car-shed and workshop is shown in Fig. 8 Extensions are now being made to the existing building to accommodate the rolling-stock which has been and will be added to the present equipment, due to the increased service which will shortly be run.

Extensions to System.—To provide sufficient power for additional trains which will have to be run to cope with the steadily increasing traffic demands on the existing lines, and also for the tram service on Harrison-road and several new suburban lines which will be opened in the near future, the power station is being considerably increased, three-phase alternating-current generators being installed generating 6,600 volts direct, the current being transmitted to several rotary converter sub-stations in outlying parts of the city by means of duplicate three-core cable laid separately on the solid system in earthenware troughing. These extensions to plant will form the subject of a future article.

SWANSEA ELECTRICITY UNDERTAKING AND TRAMWAY DEPARTMENT.*

BY C. A L. PRUSMANN, M.I.E.E., A.M.I.M.E., BOROUGH ELECTRICAL ENGINEER.

BUILDINGS.

The buildings situate at the Strand generating station comprise the following: pump-room, boiler-house, economiser shed, engine-room, battery-room, test-room, mess-room, store-room, coal stores, joiners' shop, chief engineer's office, assistant and charge engineers' office, clerk's office, timekeeper's office, bathroom, lavatories, weigh-room, passages and corridors, yards, and chimney shaft.

Pump-Room.—The pump-room is equipped with (1) one three-throw pump by Messrs. Yates and Thom, driven by a shunt-wound motor by Messrs. the British Schuckert Company. The pump is capable of delivering 2,000 gallons of water per hour through an economiser against a boiler pressure of 160lb. per square inch. (2) One three-throw pump by Messrs. Yates and Thom, driven by a single-cylinder engine by Messrs. Yates and Thom. The pump is capable of delivering 2,000 gallons of water per hour through an economiser against a boiler pressure of 160lb. per square inch. (3) One steam-driven "Weir" pump, capable of delivering 4,000 gallons of water per hour through an economiser against boiler pressure of 160lb. per square inch. All the above pumps receive their supply of water from tank situated above the pump-room, which tank is constructed in two divisions; the whole having the following dimensions, 28ft. by 7ft. by 11ft. This tank is supplied with water from the town mains, passing through "Kennedy" water-meters. The steam supply to the pumps is in duplicate, and the arrangement of feed pipes is such as to admit of the pumps delivering boiler feed to the boilers, either direct into the boilers or through the fuel economiser.

Boiler-House.—The boiler-house is equipped with five "Lancashire" boilers by Messrs. Yates and Thom; each boiler is 30ft. long and 7ft. 6in. diameter. They are designed for generating steam at a pressure of 160lb. per square inch. The furnaces are arranged for hand firing, natural draught being employed. The fuel is tipped in front of the boilers through the iron doors adjoining the railway siding, along which the coal trucks are brought. Each boiler is fitted with duplicate water-gauges, duplicate boiler feed check valves, and a pressure gauge. The boilers supply steam to the engine-room by means of duplicate ranges.

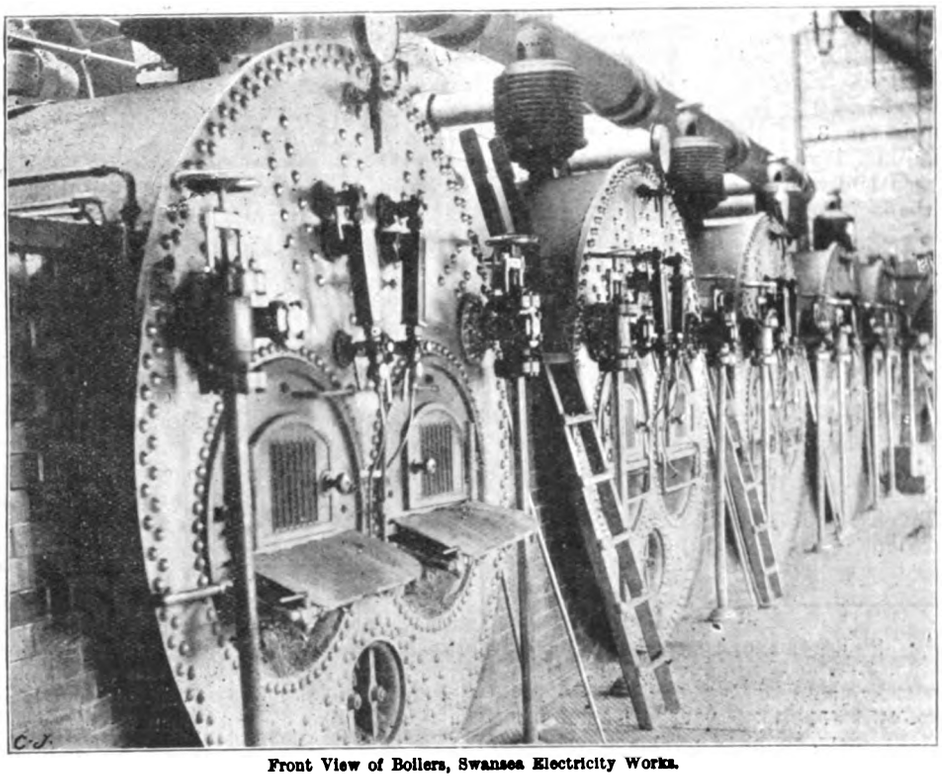
Economiser Shed.—The economiser shed is fitted with an economiser by Messrs. Green and Sons, consisting of 190 tubes, designed for working in conjunction with the aforementioned boilers. This economiser is fitted with full complement of valves, fittings, etc. The scrapers of the economiser are driven by a 1-h.p. motor, by Messrs. the British Thomson-Houston Company.

Engine-Room.—The present engine-room is equipped with the undermentioned machinery, plant, switchgear, etc.: (1) One 75-kw. shunt-wound multipolar British Schuckert dynamo coupled direct to a high-speed three-crank compound "Willans" enclosed-type engine, running at a speed of 450 r.p.m. This steam generator is suitable for lighting purposes only. (2) One 225-kw. shunt-wound multipolar British Schuckert dynamo, coupled direct to a marine triple-expansion open-type engine, by Messrs. J. and H. Maclaren, running at a speed of 150 r.p.m., and capable of developing 450 i.h.p. This steam generator is suitable for tramway and lighting purposes. (3) Two 600-kw. shunt and compound wound multipolar "British Westinghouse" dynamos, coupled direct to two marine triple-expansion open-type engines, by Messrs. J. and H. Maclaren, running at a speed of 125 r.p.m., and capable of developing 1,100 i.h.p. each. These steam generators are suitable for both lighting and tramways. The above engines are designed for a pressure of 160lb. per square inch at the engine stop-valves. All four engines are arranged to work either condensing or non-condensing. The 75-kw. steam generator is fitted with a three-throw jet condenser, by Messrs. Yates and Thom, which is driven by means of a 15-b.h.p. shunt-wound electric motor, by Messrs. the British Schuckert Company, coupled direct to the condenser. The 225-kw. steam generator drives, by means of four 1½in. ropes, a jet condenser by Messrs. Yates and Thom. Each of the two 600-kw. steam generators drive, by means of links worked off the intermediate cross-head, a surface condenser by Messrs. Maclaren. In all cases the circulating water for the condensers is obtained from the north dock. Before leaving the main steam-engines and dynamos, it may be of interest to note that when the destructor works engine and dynamo are in operation the condition of affairs will be as follows: One of the 500-kw. generators will be utilised for lighting. The 225-kw. generator at the destructor works will supply those tramways for which the Corporation have to find electrical energy, leaving at the Strand station one 600-kw. generator, to act as a stand-by to both lighting and tramways, and a 225-kw. and a 75-kw. generator to meet immediate future demands for lighting. It will, therefore, be seen that both the lighting and the tramways will be worked with a minimum of stand-by plant, which means an important reduction in the amount of capital charges. Leaving the main generators, and turning to the smaller electrical plant, this consists of: (4) One motor booster for the purpose of charging the batteries, the booster side having a capacity of 165 amperes at 185 volts. The motor side consists of a shunt-wound motor. The combined motor booster is by Messrs. the British Schuckert Company, running at a speed of 765 r.p.m. (5) One 40-kw. shunt-wound balancer, by Messrs. the British Schuckert Company. This machine is utilised for taking up the difference in load on either side of the three-wire system, and runs at a speed of 550 r.p.m. (6) One negative tramway booster, for the purpose of keeping down to within Board of Trade requirements the difference in pressure along the tramrails. This booster has a capacity of 250 amperes at 35 volts, and is by Messrs. D. Bruce Peebles and Co. (7) One milking booster. This is a portable booster for charging up individual cells of the battery, made by Messrs. the British Schuckert Company. (8) The main lighting switchboard. This is situated on the south wall of the engine-room, and is by Messrs. the British Schuckert Company, and comprises: three main feeder panels, one battery panel, one balancer panel, one total output panel, one motor booster panel, and eight main feeder panels. In addition to the above panels on the main lighting switchboard, there are two generator panels, and one feeder panel, by Messrs. the British Westinghouse Company. The whole of the above mentioned are fitted with the full complement of recording instruments, safety

*Paper read at a district meeting of the Incorporated Association of Municipal and County Engineers at Swansea, July 14.

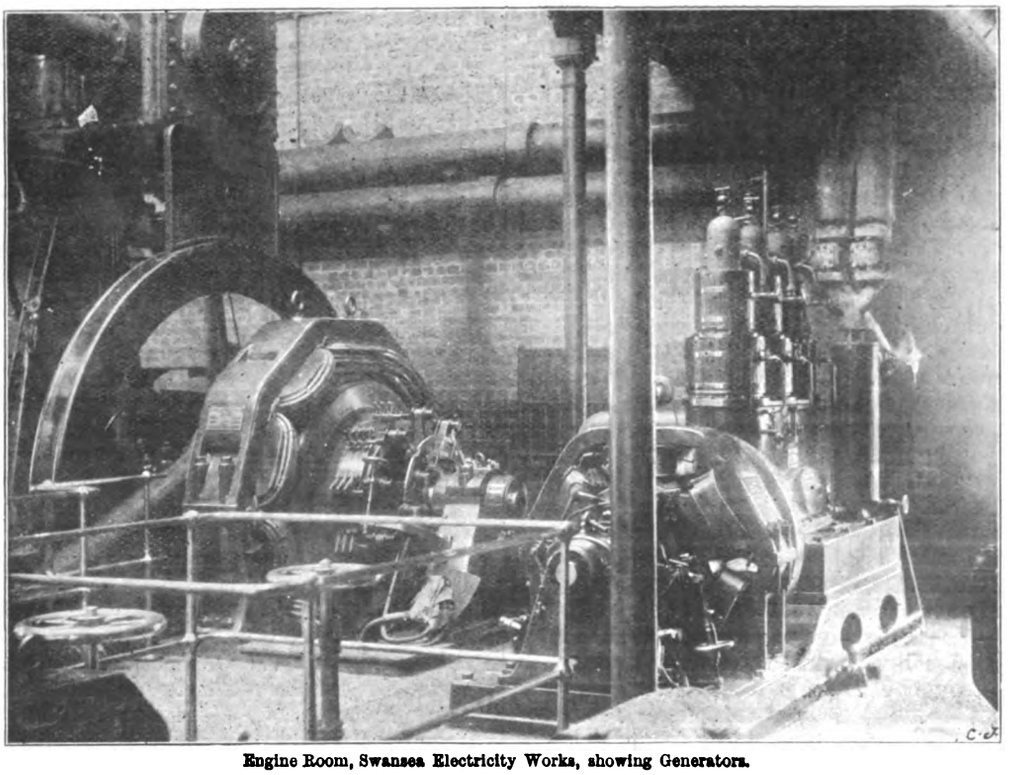
Digitized by Google

devices, switches, fuses, general instruments, and appliances. The street arc lighting board is distinct from the main board, and is arranged for controlling six series of arc lamps, consisting of nine lamps to a series. (9) The new tramway switchboard. This is situated on the east wall of the engine-room, and is by Messrs. Dorman and Smith. The whole of the switchgear, instruments, etc., on this board are mounted on blue marble. The board comprises one Board of Trade panel, one negative booster panel, one panel for the motor of the negative booster, one total output pane and two feeder panels, containing two feeders on each panel. The back of this board is particularly free to access, for inspection, overhauling, etc. (10) The steam to the engines is carried along the east and west sides of the engine-room by means of duplicate steel pipes on either side, fitted with full complement of valves, etc. (11) The engine-room is spanned by means of a 10-ton hand travelling crane, by Messrs. Carrick and Ritchie. It will be observed that a certain space of the engine-room has not been tiled. In this space it is proposed to fix the high-tension alternators, driven by continuous-current, low-tension motors for supplying electrical energy to the outlying districts.



Front View of Boilers, Swansea Electricity Works.

Battery-Room.—The battery-room is situated on the east side of the engine-room, and contains 258 cells, divided up in two halves on either side of the three-wire system. The capacity of the battery is 650 ampere-hours, and is by Messrs. the Tudor Accumulator Company.



Engine Room, Swansea Electricity Works, showing Generators.

Test-Room.—The test-room is situated on the ground floor on the south side of the engine-room, and is provided with numerous instruments for carrying out meter, arc lamp, mains installation, and dynamo tests.

Coal Stores.—The present coal stores are adjacent to the south side of the boiler-house and are capable of storing approximately 200 tons of coal.

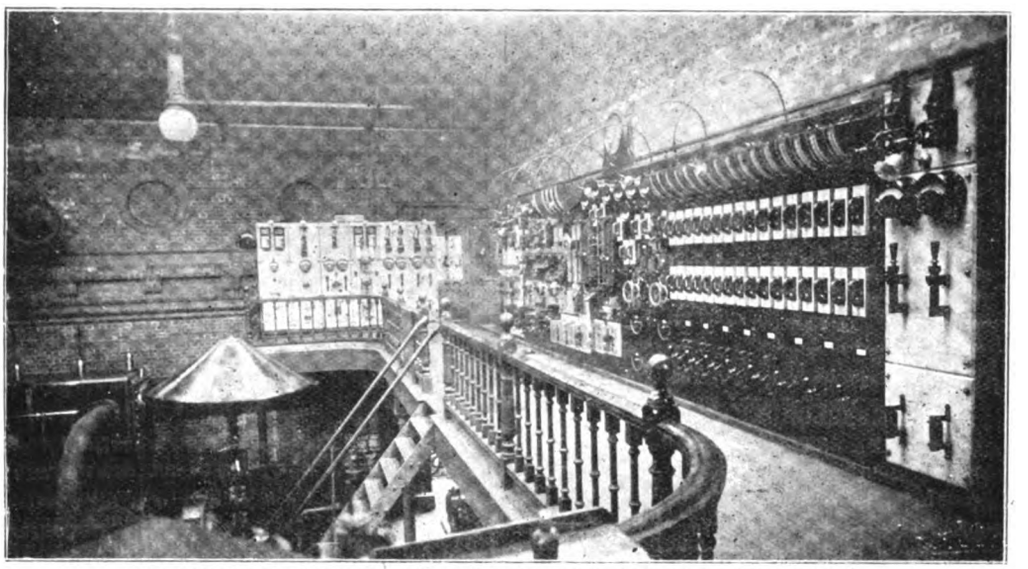
Feeders and Distributing Mains.

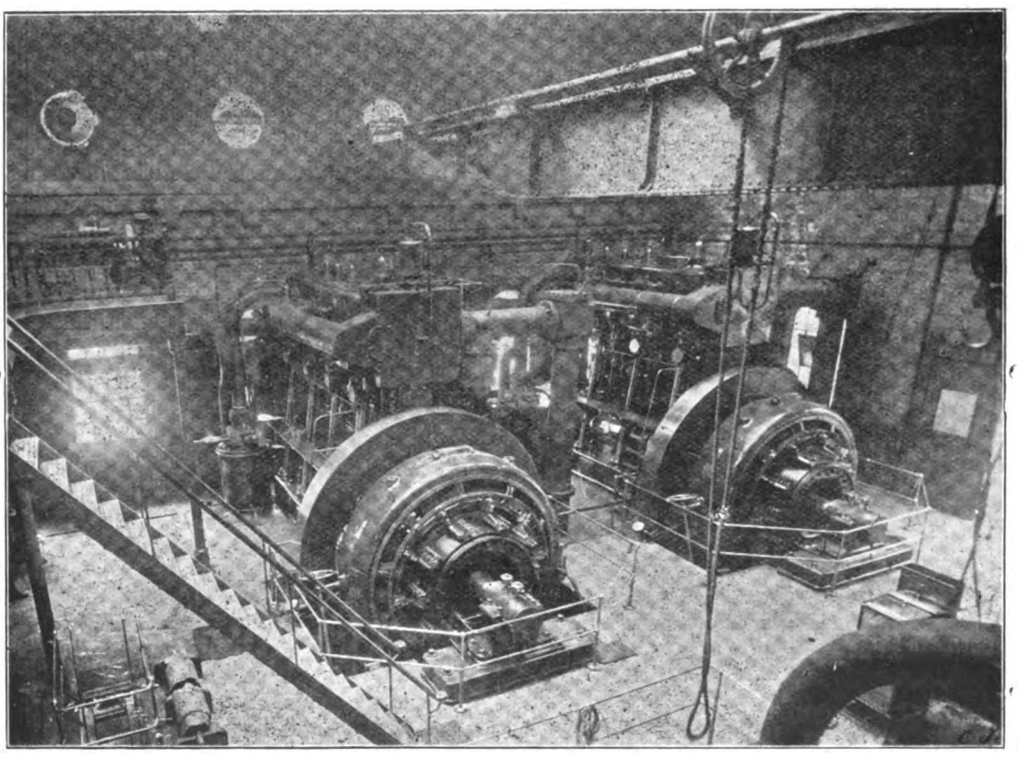
The supply of electrical energy to the town for lighting purposes is delivered by means of (1) Eight main feeders and six sub-feeders—The whole of these feeders are of the hygroscopic, triple-concentric, lead-covered type, and are drawn into 3in. "Albion Clay" and "Doulton" earthenware ducts. The cables are by Messrs. Callender's Cable and Construction Company, and vary in size from the largest, 0·4, 0·2, 0·4 square inch, to the smallest 0·2, 0·1, 0·2 square inch. (2) Main feeder cables crossing the north dock and the new cut—These are of the single-core, submarine, double-wire, armoured type, by Messrs. Callender's Cable and Construction Company, and are laid direct in the bed of the north dock and new cut. (3) Distributing cables—These are fed by means of the above-mentioned feeder cables, and are of the fibre insulation, hygroscopic, lead-covered type, laid in U-shaped earthenware troughs, filled in with bitumen, and finally covered by means of tiles. The cables have a sectional area of 0·1, 0·06, 0·1 square inch. (4) Service cables—The service cables are triple-concentric, and concentric, hygroscopic fibre insulation, lead covered, and laid in a similar manner to the distributing cables. The sectional area of the service cables used are 0·022 concentric and 0·05, 0·025, 0 05 triple concentric. (5) Feeder cables—These are connected to the distributing cables by means of feeder pillars fixed above the surface of the footways, and when these distributing cables are required to be disconnected, this is effected by means of underground disconnecting network boxes fitted with footway and roadway frames and covers. All feeder pillars and underground fittings are by Messrs. Callender's Cable and Construction Company.



Switchboard Gallery, Swansea Electricity Works, showing Lighting and Traction Boards.

Consumers' Meters and Indicators.

Consumers have fitted in their premises (1) meters made by one of the following: Messrs. Chamberlain and Hookham, Ferranti, Aron Meter Company, Reason Company, and the Bastian Meter Company; (2) indicators of the "Wright" type, made by Messrs. the Reason Company; (3) "Reason" fuse boxes are used in consumers' premises.



View of Engine Room from Switchboard Gallery, Swansea Electricity Works.

Equipment in Engine-Room at Destructor Works.

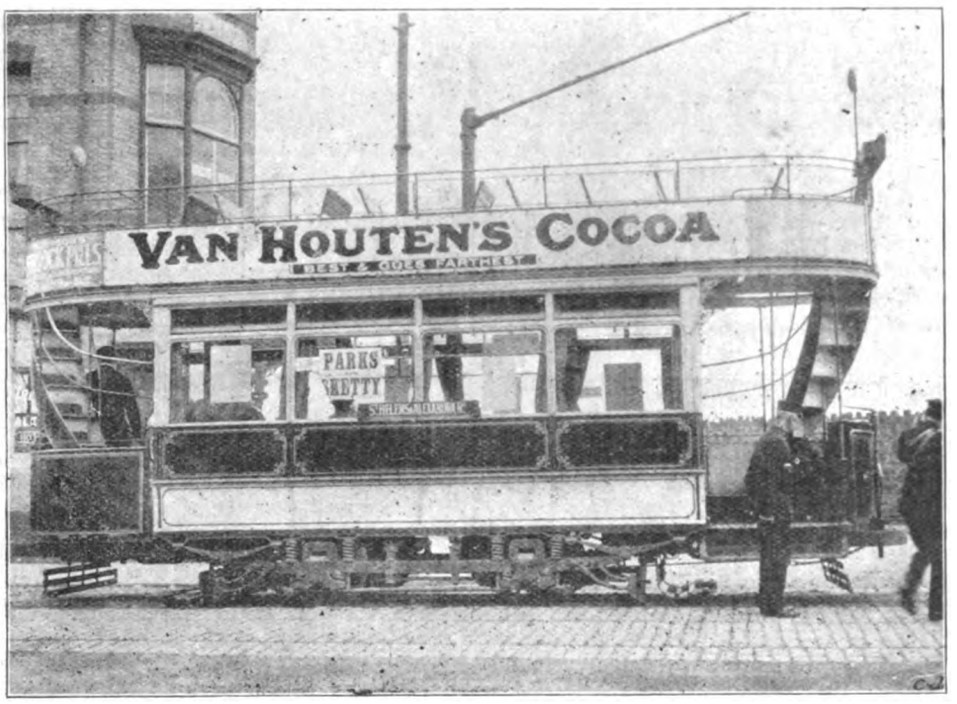
The equipment at the destructor works engine-room, which is to supply electrical energy to the new tramways and light railways, will consist of a 225-kw. engine and dynamo. This engine and dynamo have been removed

Digitized by Google

from the Strand generating station, and so altered to enable it to meet tramway requirements. A tramway switchboard will be installed, which is a duplicate of the one at present in use in the Strand station, also tramway booster. The steam to the generating set at these works will be obtained from the boiler, which in the ordinary way will generate steam by means of refuse, and the steam-pipes connecting this boiler with the steam-engine will be laid underground from the boiler in the destructor works to the engine-room. The engine-room at the destructor works is equipped with an eight-ton crane, by Messrs. Herbert Morris and Bastert. The building at these works, as far as the electricity department is concerned, comprises engine-room, offices, stores, and lavatories.

Tramway Overhead Equipment.

The Swansea Corporation have nearly completed some 12 miles of electric tramways and light railways. The bulk being now in operation, and the remaining section it is hoped will be open in the near future. The overhead equipment of these tramways and light railways has been carried out by span-wire and bracket-arm construction; no centre poles have been employed, and no bracket arms over 15ft. 6in. have been used. The line has been erected for straight under-running trolleys, with fixed trolley heads.



Electric Tramcar, Swansea.

Owing to the peculiar atmospheric conditions which prevail in Swansea on account of the various works in the neighbourhood, it has been deemed advisable to use only phosphor-bronze for span and guard wires, as against the usual practice of steel wire, as it has been found that the life of a steel wire under the conditions in Swansea is very short indeed. This course, undoubtedly, has added very considerably to the cost of construction, but it is hoped that the maintenance of the overhead equipment will be very much reduced on this account, and the life greatly prolonged. The size of the trolley wire used is 2/0 S.W.G. Double insulation is used throughout. The whole of the rails are bonded by means of 4/0 "Chicago" crown bonds. Two bonds being used at each fishplate. The track is cross-bonded, and clear way bonded every 40 yards. Special bonds are used at all points, crossings, junctions, etc. Every third tramway pole is earthed on to the rails. In accordance with usual practice, the line is divided up into half-mile sections, and is fed at a pressure of 550 volts. The tramways and light railways in Swansea are interesting from one or two standpoints. Prior to the laying down of the Corporation tramways and light railways, the electrical tramway system was entirely in the hands of Messrs. the Swansea Improvements and Tramways Company, who owned the whole of the overhead equipment, cables, etc., and who supplied electrical energy to the tramways from their own generating station. The new tramways and light railways are leased to the company under certain conditions existing between the company and the Corporation, the company supplying electrical energy to certain portions of the new lines, and the Corporation supplying the remainder, and a very considerable length of the old company's lines are now being supplied by the Corporation. It will, therefore, be seen that the tramways and light railways in Swansea are supplied by means of three distinct generating stations, two of which are owned by the Corporation, the third by the company. The two owned by the Corporation are the main generating station situated in the Strand and at the destructor works. In the ordinary course those sections of tramways which the Corporation have to supply with electrical energy will receive a supply from the destructor works. The main station will take up the supply on those occasions when the load on the tramways is too great for the destructor works to deal with or when the destructor works are shut down for repairs, overhauling, etc. As far as possible, arrangements have also been made to enable the tramway company's station to supply current to those sections, which in the ordinary course receive their energy from the Corporation works, in the event of a breakdown happening at the Corporation works, and *vice versâ*. By adopting this course, it will be seen that the amount of stand-by plant is reduced to as low as possible, as the spare machinery at the Strand station will act as a stand-by to both tramways and lighting. It is, of course, assumed, and the writer believes safely so, that a breakdown to lighting and tramways will not occur simultaneously. The remaining points in connection with the new light railways which should be mentioned are, namely, running cars over the drawbridge spanning the north dock lock, and the swingbridge crossing the River Tawe. In the case of both these bridges, the current is automatically disconnected and connected, when the bridges are open and closed, in such a manner as to make it impossible for a car to approach the dock or the river to within a dangerous distance while the bridges are open. The writer is not aware that a similar case has had to be dealt with in any town in the United Kingdom. The work of installing the overhead equipment has been entrusted to Messrs. Dick, Kerr, and Co. It is interesting to note that all the tramway poles have been made in the town—namely, by Messrs. the British Mannesmann Tube Company.

Tramway Cables.

The whole of the tramway cables for the Corporation's

Digitized by Google

new tramways and light railways consist of vulcanised, non-hygroscopic, unsheathed cables, laid solid in 2½in. earthen troughs filled in with bitumen, and finished off with tiles on top. Alongside all of these cables in every case have been laid a number of "Albion Clay" 3in. earthenware conduits, so that in the event of extensions being required in the future, cables will be able to be drawn into these spare ducts without the reopening of any roadway except at intervals of approximately 100 yards, where it may be required to build draw-pits. This, however, will cause very little, if any, inconvenience to traffic of any description. The reason that these draw-pits have not been put in during the laying of the spare ducts, is on account of the fact that possibly the spare ducts may not be required for a considerable time, and, therefore, in the meantime, the capital outlay of the draw-pits and frames and covers is saved, and if these are required at a future date, they can very easily be installed. It is interesting to note that the whole of the tramway cables, after entering the Strand generating station, are kept absolutely distinct from all lighting cables, and are laid in a separate trench very easy of access. It is, therefore, quite impossible to make the mistake, in the case of an emergency, either to lighting or tramway cables, of confusing the two sets of mains.

ELECTRIC TRACTION IN GERMANY.

According to the latest statistics published in the *Elektrotechnische Zeitschrift*, it appears that the towns and districts in Germany provided with electric tramways or railways numbered 138 on Oct. 1, 1904, an increase of four as compared with the returns for 1903. The length of route covered has increased about 100 km., amounting to 3,800 km. The number of motorcars employed has increased from 8,702 to 9,034. This increase is not in proportion to that of the length of route traversed, whence it may be deducted that the traffic on the older lines has increased in average density. The total output of the generating plant available for traction load has increased by only about 1½ per cent., while the total output of accumulators on traction load shows an increase somewhat greater in extent, the total accumulator capacity installed amounting on the date in question to 39,809 kw. The small increase in generator output is accounted for by the fact that the Hanover tramways return only 4,555 kw. as against 10,063 kw. in 1903. No material change has occurred in the system of working most in vogue. There is a strong tendency to abandon conduit and accumulator systems in favour of the overhead trolley throughout for street railways, principally for reasons of economy. Mixed working by trolley and accumulator cars is retained only in Dresden, while trolley working in conjunction with sections of conduit line exists in Berlin, Dresden, and Dusseldorf. The reliability of the conduit system as compared with that of the overhead trolley line leaves much to be desired, according to German experience, so that its entire substitution by the last-named is apparently only a question of time. Lead and return overhead conductors are provided over sections of the Königsberg lines. Accumulator traction pure and simple on tramways is retained only on a section 4·2 km. long in Bremerhaven, while the remaining portion of the system, comprising some 11·4 km. of track, is still worked by horses. It is, however, intended to equip the whole of the lines for the overhead trolley system of working. On the other hand, it is interesting to note that accumulator traction has held its own on railways proper, and even been extended in some instances. The Ludwigshafen-Mundenheim local railway still retains its service of accumulator cars after 10 years' experience of their working. This line has a length of 5·2 km. It maintains two cars, one being equipped with two motors of 12 h.p. each, and the other with one motor of 20 h.p. No figures are given as to the cost. Further, the Kgl. Bayer-Pfälz Railways have accumulator traction on 10 sections of line, with a total length of 288 km. In this case six accumulator cars are employed, each equipped with two 40-h.p. motors. These cars act as auxiliaries to the steam-hauled trains for local service on the main and branch lines of the system, ordinary passenger cars being attached to form trains when necessary. Similar services are being tried, more or less experimentally, on the main-line sections Augsburg-Gessertshausen, Karlsruhe-Graben, and Dresden-Cossebaude. A third rail is used on the main-line section Berlin-Gross-Lichterfelde, and on the Berlin elevated and underground railway; while an iron conductor rail is also employed on the Barmen-Elberfeld suspended railway. It is noteworthy that single-phase alternating current continues to gain ground. Due to the successful trials on the main-line section Niederschönweide-Spindlersfeld, this system has been adopted for the Hamburg-Altona Railway and its extensions, the work being already in hand. Moreover, single-phase has been substituted by the Siemens-Schuckert Co. for the three-phase system of working formerly employed on the Murnau-Oberammergau local line. Other traction plants of similar type have been installed by German engineers in Austria, Belgium, and elsewhere, and plans are in hand for the introduction of the same system on the Berlin town and ring railway. With regard to traction without rails, minor difficulties, it appears, have been overcome, and the system is now giving satisfaction in working. Experience so far also promises commercial success, but it is too early to speak of definite results. In all, there are six routes worked on this system, having a total length of 21 7 km., the carriage of goods being the principal use to which the cars are put.

It remains to add that the large volume of traction work in hand promises well for future returns from a relative point of view.

GRIMSBY ELECTRICITY ACCOUNTS.

In the accounts of the Grimsby Corporation electricity department for the year ended March 31. 1905, the total capital expenditure to that date is stated as £80,937. Abstracts of the revenue account, balance-sheet, and statement of electricity, sold, etc. are appended.

Revenue Account.

Dr. Expenditure.	£	s.	d.
To generation of electricity	3,014	3	9
Distribution of electricity	253	3	6
Attending and repairs to public lamps	354	5	2
Rents, rates, and taxes	317	8	4
Management expenses, salaries, etc.	835	11	4
Law expenses negotiating loans	172	17	3
Special charges—insurances, etc.	76	18	0
	5,024	7	4
Amount set aside for bad debts	68	0	1
Balance carried to profit and loss account	5,786	7	3
	£10,878	14	8

Cr. Income.	£	s.	d.
By sale of current by meter	10,446	11	0
Rental of meters and sale of lamps	277	6	7
Discount received	154	14	9
Balance from last account		2	4
	£10,878	14	8

General Balance-Sheet.

Dr. Liabilities.	£	s.	d.
Capital account—amount received	79,000	0	0
Sundry creditors	2,501	4	3
Balance at credit of net revenue account	895	5	9
Sinking fund account	6,841	9	6
Provision for bad debts	68	0	1
	£89,305	19	7

Cr. Assets.	£	s.	d.
Capital account—amount expended for works	80,937	15	6
Stores on hand	1,852	7	8
Sundry debtors for current supplied	2,910	12	4
Other debtors	208	4	11
Securities held (cost price)	1,390	17	10
Sinking fund on deposit	1,918	8	0
Cash in hand	87	13	4
	£89,305	19	7

Statement of Electricity Generated, Sold, etc.

Quantity generated in B.T.U.			1,159,144
Quantity sold: Private consumers by meter	458,224		
Public lighting	102,986		1,024,982
Traction	463,772		
Quantity used on works			58,087
Quantity unaccounted for			76,045
Total maximum supply demanded (kilowatts)			647

Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

Post Free, Payable in Advance.)

Bound Volumes of "The Electrical Engineer," containing half-year's copies, bound in Dark-Blue Cloth, Gold-Lettered, price 8s. 6d. New Volume, January to June, 1905, now ready.

"THE ACCOUNTANT" AND DEPRECIATION.

It is with a feeling somewhat akin to despair that we challenge the *Accountant* to make good its position with regard to municipal work, and especially in regard to depreciation of tramways. In its last issue it has a leading article on "Municipalities and Depreciation," the tenor of which is, if our memory serves us correctly, of the same character as of many a previous article in its columns. The *Accountant* aspires to the position of autocrat in the cult of accountancy. To venture to differ with its dogmatisms is to put oneself into jeopardy. A slip is serious, and will result in the one who slips being pilloried to all eternity as far as it is possible for the *Accountant* to do so. Still, the subject is of importance, and must not be left in the slip-shod position it holds, where every writer and speaker defines everything as it pleases him in order to make his own case good. At present there is no shadow of agreement anywhere, but on this point dogmatism. From our reading of the *Accountant* we gather that all municipal accounts are kept in a childish manner, while corresponding companies' accounts are flawless. Is it possible to get a common starting point—where all are agreed—then to see wherein we differ in the various divergencies from that point? Municipal action is open to enough adverse criticism without innuendo or variant definitions. Here is a problem for the *Accountant*. The B.E.T. is a company; the Brighton concern is that of a municipality. Both keep accounts. The accounts such as they are can be examined. Will our contemporary with its wealth of expert knowledge examine these sets of accounts and pronounce which treats depreciation in the best manner? We also want to know what really a compulsory sinking fund is if it is not compulsory depreciation? If, as we for the moment dogmatically assert, a sinking fund is depreciation, the minor question may arise, is it too small? So far as a municipality is concerned, the question of enough is settled by a higher authority; hence if the amount is in the estimation of the *Accountant* not enough, its work should be to prove its case to the higher authority. What exactly does the *Accountant* mean when it writes about depreciation? Till we get that definition we cannot tell how far the sneering suggestiveness of the phrase "certainly ought to be no difficulty in showing *very* substantial profits" is warranted. A large part of the article we have referred to merely discusses a verbal quibble. The *Accountant* says: "We altogether fail to grasp the point of the argument." If that be quite true, it means that the writer is incompetent to criticise; but is it? We feel grave doubts on this point. The committee criticised says that repairs are made out of revenue. The engineer says no extensive replacements will be required for five or six years, also that revenue is increasing. The suggestion of the committee is, rightly or wrongly, that the increasing revenue will be sufficient to meet any demands for repairs, etc., even at the end of five or six years; and, therefore, no further special provision is necessary. The so-called dead charge is surely partly or wholly met by the sinking fund, and does not need any separate fund unless the sinking fund is shown to be too small. The whole case may be summed up in a few words. Municipal affairs are to be condemned, and the mode of condemnation is to discuss "depreciation"—a blessed word like Mesopotamia—which nobody defines or understands. Nothing the municipalities can do in their accounts amounts to depreciation, and any lapse in the accounts is due to lack of depreciation, but what the change is to be in order to conform to abstract requirements neither the *Accountant* nor any of the opposition ever tell us. If the respected opponents to municipal trading will tell us that such trading is neither fish, fowl, nor good red herring,

Digitized by Google

and that trading of any kind involves risk, we will agree; but to be continually harping upon a string that only exists in the imagination of dreamers serves only to rouse the combative instincts of those who want to get at the truth, and only the truth. The one great question so far as accounts are concerned is, are they clear enough to show solvency or insolvency? Is there absolute certainty that assets are equivalent or more than equivalent to liabilities? The question of the rights or wrongs of municipal trading is another matter.

CORRESPONDENCE.

ADDRESS WANTED.

Will "W. J. H.," the writer of an article entitled "Notes on the Care and Management of Dynamos," recently published by us, kindly send his full address.—[ED. *E. E.*]

ROYAL COMMISSION ON LONDON TRAFFIC.

In our last issue we published a *résumé* of the report of the above Commission dealing specially with their recommendations as to tramway extensions and road improvements.

With respect to tube and other underground railways, the adequacy of the central urban facilities of transport for the distribution of passengers arriving at the main-line stations in London is discussed, with the conclusion that after the underground railways now under construction or in process of electrification are in operation, all the main-line terminals, with the exception of Paddington, Victoria, and Fenchurch-street, are sufficiently provided for. To meet the case of Victoria the Commission recommend the extension of the North-West London Railway from Marble Arch.

In regard to urban railways the conclusion is stated as follows: "We have come to the conclusion that, when the 'tube' railways already authorised have been completed, with the addition of the line we have suggested from Victoria to Marble Arch, the most pressing requirements of railway communication within the central area, as distinguished from the suburbs, will have been fairly provided for. We think, however, that greater attention should be paid to providing interchange stations wherever lines running north and south intersect those running east and west, and that wherever it is possible this accommodation for the public should be afforded."

The Commission then discuss the practicability of securing the construction of further underground railways in London. They express their reliance on private enterprise to provide any extensions needed. All that is necessary is to see that no discouragement shall be created for private enterprise by the system of procedure under which railway undertakings are authorised, or by the imposition of undue burdens proposed on, or exaction of impossible conditions from, promoters. If public assistance is inevitable, and the Commission think that neither the construction of unremunerative underground railway lines or the running of unremunerative trains should be laid on railway companies, the Commission suggest various methods of assistance—the remission of rates, direct subscription to capital or guarantee of receipts by local authorities, permission to railway companies to acquire large tracts of land before development, and, in cases, permission for construction underneath the parks.

The Commission then discuss the relative advantages of tubes and shallow railways under the four heads of (1) economy of cost of construction; (2) avoidance of interference with street traffic; (3) avoidance of damage to property; (4) ventilation, convenience of access, etc. But although they report in favour of the shallow railway as against the tube, they recognise that the construction of the former is in may cases quite impracticable.

The Commission state that all large systems of mechanical traction can be worked most economically and with the greatest advantage to the public when they are under one and the same management, and believe that amalgamation can be carried out in such a way as to be profitable to the shareholders and advantageous to the public, but they think that it should only be sanctioned on terms and conditions which fully secure the interests of the public.

The Powers and Duties of the Proposed Traffic Board.

The authority which the Commission recommend to be established should be a Traffic Board, and should discharge definite and practical duties. It should make a yearly report to Parliament on locomotion, transport, and traffic in "Greater London," dealing with the whole subject, including such matters as the control of traffic, the regulation of the statutory powers of breaking up the streets for various purposes, the removal of any special obstructions to traffic, the provision of new lines of railway or tramway, and calling attention to any errors or oversights in the maintenance of streets and roads on the part of local or street authorities. It would also deal with the question of street improvements, including street widenings and the construction of new streets, as well as the provision of alternative routes, and of facilities for dealing with cross traffic.

The most important function of the Board would be the preliminary examination, before consideration by Parliament, of Bills seeking statutory powers for the construction or extension of works affecting the means of locomotion and transport in "Greater London."

The Board would sit continuously, and Bills that required serious amendment could remain before the Board until the necessary antecedent formalities were completed. The Board would use its discretion as to suggesting amendments in Bills, in order to bring the particular proposals before it into harmony with any general scheme which might be approved for the provision of facilities for locomotion and transport in London. It would be at the option of the promoters of the Bill to accept or reject such suggestions. The Board could also with advantage settle, subject to the approval of Parliament, all clauses for the protection of public or private interests. On completion of their inquiry, the Board would pass on the Bill, with all amendments accepted by the promoters, to Parliament, accompanied by a report. The members of the Board, or any of them, or a representative of the Board, might be required to attend before select committees of Parliament to explain the grounds of their report or recommendations, and to give advice on any subjects referred to them. The Board would also deal with or report upon any questions which might be referred to them by a select committee of Parliament.

If required to do so by Government or by a local authority, with the approval of Government, the Board should prepare schemes for works for or in connection with or report upon the provision of means of locomotion or transport in any district. The Board might also hear and determine all disputes relating to through running or the interchange of traffic on or between railways and tramways, or as to by-laws, whether between local authorities or private companies; and could perform a useful service by facilitating and suggesting amalgamation or joint working under suitable conditions, which its position as preliminary examiner of Bills would afford it special facilities for so doing.

The services of the Board would be valuable in connection with the abolition of the "veto" in the case of tramways, because the existence of such a body would at any rate lessen the objection to such a measure on the part of the authorities now possessing the "veto." Though the nature of the duties which it is suggested the Board could perform have been indicated in general terms, the Commission strongly deprecate the idea that the list of duties is exhaustive. Experience and further consideration will doubtless show that other duties may, with advantage, be added to those which they have mentioned.

As regards the constitution of the Board, what is required for such purposes, in the opinion of the Commission, is a small number of specially qualified persons, selected solely on the ground of their competence, and holding office for a con-

Digitized by Google

siderable period, subject always to good behaviour. They suggest the Board should consist of a chairman and not more than four nor less than two other members; and prefer that there should be not more than three members in all. No member of the Board should engage in any business, or have any interests, which might conflict, or appear to conflict, with the proper discharge of his official duties; nor should he be a member of any local authority in London; or have any occupation which would limit the time which he could devote to the work of the Board. What appears, they think, to be really essential is that the members of the Board should be capable men of business, energetic, impartial, and able to devote, if necessary, their whole time to the work of the Board. The Board would keep in touch with all the local and other authorities in Greater London, and maintain a friendly attitude towards them and towards all companies and persons that work railways, tramways, or other means for facilitating locomotion and transport. The cost of the Board, with that of its establishment, in excess of the fees levied in connection with it, should be levied rateably from the local areas within its jurisdiction.

THE ADMINISTRATIVE COUNTY OF LONDON AND DISTRICT ELECTRIC POWER BILL.

(*Continued from page 97.*)

Amongst other witnesses for the Bill was Sir WILLIAM WHITE. As director of Messrs. Swan, Hunter, and Richardson, shipbuilders, he was convinced of the advantage of electric driving for shipyards. His firm took power from the Tyneside company. A similar movement was taking place in other Tyneside shipbuilding yards, and, indeed, among the industries of the district generally. This was owing to the success of the great system for supplying electric power established in that part of the country by the promoters of the present Bill. His firm paid $\frac{7}{10}$d. per unit for electrical power, and had found it profitable to abandon their own generating station. The experience of Tyneside convinced him that the scheme before the committee would be beneficial to London.

A number of manufacturers were also heard in favour of the Bill.

Mr. J. FALCONAR, as director of the limited company formed to promote the Bill, explained the financial side of the scheme. His co-promoters numbered 70, of whom 42 were London gentlemen largely interested in manufacturing enterprises, and the rest were gentlemen mostly connected with the Tyne. The amount first suggested as sufficient for promotion purposes was £12,000, but this amount was afterwards increased to £50,000, of which £47,000 had been subscribed. That was the actual cash which had been subscribed up to the present, but the witness had no doubt that the capital of five millions sterling would be raised without difficulty. The promoters and their friends would take up the whole of the first issue without appealing to the public. So far as the financial side of the scheme was concerned, the promoters had been advised by Baring Bros. The Newcastle Company had had no difficulty in raising a million, and recently had obtained £350,000 for the Durham power scheme. He had carefully considered the purchase clause, and thought that the 50 years' period was reasonable. The period recognised by Parliament under the Electric Lighting Act of 1888-89 was 42 years, and he had started with that as a basis, and having regard to the fact that one must expend one's capital in anticipation to a much larger extent when dealing with a supply of electricity for power purposes than when dealing with lighting. Some allowance should, therefore, be made on that account. Under the Electric Lighting Acts there was no sliding scale, the companies being at liberty to make as much as they could out of the public during their period of concession. In such a business as was contemplated under the Bill there must be very heavy initial capital expenditure, and returns would not come in for some years. Success depended upon liberal and prudent expenditure of capital as demands arose; there must be looking ahead, and the promoters must be prepared to undertake the risk. The terms of purchase would be the amount of capital expenditure at the date of transfer certified by a Board of Trade auditor year by year. There would be considerable advantage in definitely fixing the terms. Investors would know what the purchase price would be. Much injury had resulted in the past from the doubt as to what a company would receive in the event of purchase. Nobody knew the effect of the purchase clause in the Tramway Act until the first term of 21 years ran out, and then there was great difference in judicial opinion even in the House of Lords. The purchase clause had been submitted to the Board of Trade, and certain verbal alterations had been made. As regarded opposition from local authorities, the following had withdrawn their objections to the Bill: the Borough Councils of Chelsea, Greenwich, Stepney, and Wandsworth, the borough of Croydon, the Urban District Councils of Barking Town, Grays Thurrock, Wanstead, Woodford, Chislehurst, Bexley, Erith, and the Maldens and Coombe, the Rural District Councils of Croydon, Dartford, and Bromley, and the Essex County Council. The following companies had also withdrawn their opposition: the Kent Electric Power Company, the County of London Electric Supply Company, the County of Surrey Electric Power Distribution Company, and the Bromley Electric Power and Lighting Company.

The principal sub-section in the clause for the protection of Croydon reads as follows: "(1) The powers of the principal Acts and this Act and of the Acts incorporated herewith shall not be exercised within the county borough of Croydon, except (*a*) for the purpose of obtaining access through the said borough to places beyond; (*b*) for the purpose of supplying energy to railway companies whose lines pass through the said borough or to any dock, canal navigation, or Government department; and (*c*) for the purpose of supplying energy to the Corporation by agreement only for the purpose of any tramways, waterworks, electrical, or other undertaking. (2) Any electric lines proposed to be laid down by the company within the borough for the purposes mentioned in the preceding sub-section shall be laid down in such lines or routes as the Corporation and the company may agree, and such electric lines shall be laid in trenches of such reasonable dimensions as the Corporation in their discretion may direct in writing under their common seal, and the company shall be subject to any reasonable terms and conditions which the Corporation may from time to time attach to any such consent." The remaining sub-sections make the company responsible for moving mains in the event of street widening, and for any damage done by the construction of mains to Corporation property.

Under cross-examination, Mr. Falconar said that there was nothing in the Bill to prevent the promoters making a profit by the sale of their right. The reputation of the promoters was, however, at stake. Two million pounds would suffice to start the undertaking. There were no provisional contracts or undertakings or understandings with German firms or anybody else; the promoters were untrammelled by any conditions; manufacturers generally were their friends, and a good many local authorities and companies.

The CHAIRMAN asked if the Board of Trade, through its auditor, would enforce a reasonable allowance for depreciation of plant.

Mr. FALCONAR said there could be no doubt of that, and, in further defence of the purchase clause, said it would protect the public against a recurrence of what took place when the water companies were bought up. In some cases water companies got three times the amount of their capital expenditure. Negotiations were proceeding with other companies in addition to those mentioned, but no further actual agreements had been arrived at.

Mr. C. PELHAM, the secretary of the Board of Trade, made a statement as to the purchase clause, but would not express any opinion officially. He did not go into the witness chair. He said that the Board of Trade had seen the promoters and had suggested certain amendments to the clause which would make it workable. At the same time the Board was not prepared to express any opinion as to the policy of the clause, as they had heard no evidence for and against it, and, consequently, had nothing to guide them. The only guide which the Board had in the matter was

Digitized by Google

the recommendation of the Joint Committee that bulk undertakings should not be purchasable by the local authorities. That recommendation had been given effect to as regards power schemes generally. As to the price, the terms proposed by the promoters were certainly far more favourable than the terms of the 1888 Electric Lighting Act. He knew of no precedent for the price being fixed by the future expenditure, and mentioned the case of the purchase of the bridges by the old Metropolitan Board of Works, when the price was fixed by the capital invested. That principle had also been adopted in the Bill promoted by the Government in regard to the Port of London. The Board of Trade was not, however, prepared to express an opinion as to whether that was the right method of fixing the price. It ought to be made quite clear that the depreciation fund at the time of purchase should go over to the purchasing authority. It was certainly reasonable that a power distribution company should have a longer time than that given to an ordinary company working under the 1888 Act. As to the desirability of having the clause at all, he could not at present give any opinion.

After further evidence from Mr. FALCONAR and Mr. G. FARRER, of Messrs. Baring Bros., the case for the promoters was closed. The last witness said that his firm would be willing to finance the scheme.

Mr. FREEMAN, K.C., representing metropolitan borough councils, opened the opposition to the Bill.

Mr. C. H. WORDINGHAM was the first witness and criticised the Bill at length. He disputed the accuracy both of the capital outlay estimates and also those dealing with income and working costs. He contended that the assumptions on which the promoters' figures were based were incorrect. He did not think there would be an enormous demand for electrical energy at ½d a unit, and he considered that sufficient notice had not been taken of the development of the gas-engine as a source of power.

ELECTRIC WINDING MACHINES.*

BY PROF. PAUL HABETS, OF BRUSSELS.

(Continued from page 89.)

ELECTRIC MOTORS FOR HAULAGE: THEIR STARTING PROPERTIES.

The machines used for electric haulage are either three-phase asynchronous motors or continuous-current motors. The latter may be shunt-wound, or separately excited. Both types of machines possess a remarkable degree of self-regulation—*i.e.*, their speed only varies slightly with a considerable variation of load.† This property makes the machine very easy to manipulate. The driver need not trouble about the speed, as it never exceeds the normal speed much, even when the resisting torque is negative, in which case the motors turn into generators sending energy back to the station. Continuous-current series machines, although used for electric traction, are not suitable for haulage, as they run away when the load diminishes. The advantage of a better starting torque, which these machines can furnish, is, however, only relative, as motors of the other types can easily produce torques three or four times the normal one. Such torques are necessary, as the resisting moment at the end of the acceleration period is often double as great as the rate velocity moment. The starting of electric motors requires special contrivances, on the design of which the consumption of energy during acceleration depends. We have shown that during the acceleration period the motor must develop a torque given by curve A B′ (Figs. 2, 3, and 5) in the cases treated above. As the author wishes to discuss the starting properties of these motors more thoroughly, he thinks it would not be out of place to give a short account of their mode of working.

Three-Phase Asynchronous Motors.—The torque produced by a polyphase asynchronous motor is (1):

$$C = \frac{K^1 H^2}{r} \times \frac{\omega_1}{1 + \frac{\omega_1^2 L^2}{r^2}} = K^1 H^2 \frac{1}{\frac{r}{\omega_1} + \frac{\omega_1 L^2}{r}}.$$

K^1 is a coefficient; H the rotary magnetic field due to the inducing currents; ω_1 is the slip which is equal to the difference of the angular velocities (ω) of the rotary field and (ω^1) of the induced field or rotor; r the electric resistance of the rotor circuits; L their coefficient of self-induction. The angular velocity ω is equal to $\frac{2\pi f}{2p}$, where f is the frequency of the current and $2p$ the number of inductor poles. Under normal conditions, the velocity ω^1 does not differ more than 2 or 3 per cent. from ω, hence $\omega_1 = 0{\cdot}02$ to $0{\cdot}03\ \omega$. When the intensity of the field is constant, the torque will be a function of the slip only. In Curve I., Fig. 6, the ordinates represent the torque, and the abscissæ, which are reckoned positive to the left of the origin, O, represent the slip. When the slip is zero the torque is also zero; and if the rotor was driven at a speed ω^1 larger than ω, due to a negative resisting moment, the motor would become a generator and would oppose the resisting moment.

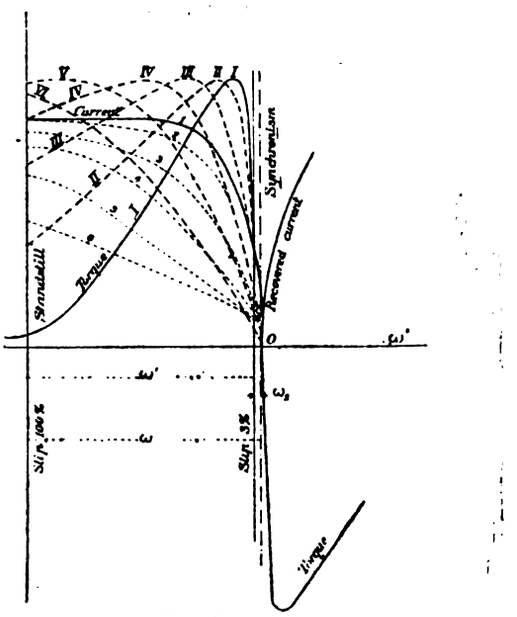

FIG. 6.

Curve I. also shows that in the neighbourhood of synchronism, the torque of the motor may vary between wide limits without causing much variation in speed. When ω_1 increases progressively from zero, the torque will also increase progressively, and becomes a maximum when $\frac{r}{\omega_1} + \frac{\omega_1 L^2}{r}$ is a minimum—*i.e.*, when $\frac{r}{\omega_1} = \frac{\omega_1 L^2}{r}$ or $\omega_1 = \frac{r}{L}$; the maximum torque will be $C_{max.} = \frac{K^1 H^2}{2L}$. The torque will now diminish as ω_1 increases progressively from $\frac{r}{L}$, and when ω_1 is equal to ω, then ω^1 will be zero and the motor will come to a standstill; we have then

$$C = \frac{K^1 H^2}{r} \times \frac{\omega}{1 + \frac{\omega^2 L^2}{r}}.$$

It will be noticed that the torque changes sign with ω_1—*i.e.*, it becomes a resisting moment when ω_1 is greater than ω. The maximum torque may attain a value three to four times greater than the normal torque corresponding to $\omega_1 = 0{\cdot}02$ to $0{\cdot}03\ \omega$. Curve 1 (Fig. 6) shows how the current varies with ω_1; it will be seen that at starting (standstill of rotor) the current is notably stronger than at the normal speed. In the case of powerful motors (above 5 h.p. or 7 h.p.) a current of such strength cannot be taken from the mains without causing an inadmissible fall of voltage, nor are the motors designed to carry such a current; the small torque which corresponds to $\omega_1 = \omega$ is not sufficient to start the rotor, especially if it has to drive a winding

* Paper read before the Institution of Mechanical Engineers (translated from the French).

† On condition that the difference of potential between the terminals of shunt or separately excited machines is constant.

Digitized by Google

machine. For this reason we must adapt some contrivance by which we can increase the torque and reduce the current.

Starting Rheostat.—The only method which has been used with three-phase motors for driving haulage machinery consists in inserting variable resistances, r^1, in series with the three circuits of the rotor. We must therefore substitute $r+r^1$ for r in the formulæ, if r^1 is non-inductive. The maximum torque may thus be produced when the slip is $\omega_1 = \frac{r+r^1}{L}$, and by giving r^1 a value which will make $\omega_1 = \omega$, we will have the maximum torque at starting. These conditions are represented by Curves VI., 6. The resistance, r^1, inserted in the rotor circuits prevents the currents from rising too much, notwithstanding the large slip, ω_1, and hence the currents in the inductors will not exceed the normal strength. By reducing the resistance, r^1, successively, the torque and current curves change respectively to V., 5; IV., 4; III., 3; II., 2; and finally to I., 1, when the last resistance has been cut out. The use of a starting rheostat causes considerable loss of power during the period of acceleration. The current will be proportional to the resisting moment given by curve A B', and as the voltage (?) (*tension du reseau*) is constant, the

Liquid Rheostat at Preussen II. and at Grand Hornu.

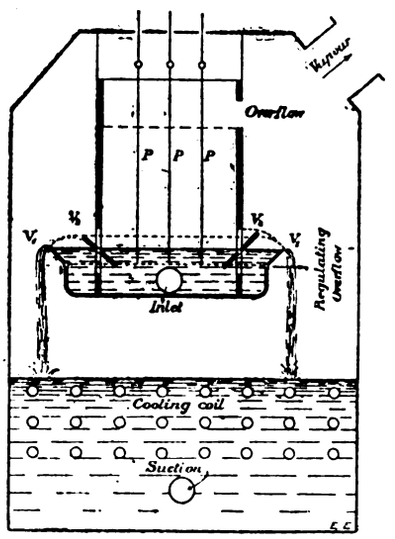

FIG. 7.

electrical energy absorbed will be equal to this moment multiplied by the angular velocity and the efficiency of the motor at such a charge. This loss will be less felt when the startings are less frequent; when the pit is very deep, the period of acceleration will be small compared with the period of constant speed. With regard to simplicity, this method is certainly superior to any other, and for this reason it is always adopted where three-phase motors are used for driving haulage machinery. The Allgemeine Elektricitäts-Gesellschaft of Berlin have designed a rheostat with liquid resistance, consisting of two vessels, the one above the other. The liquid is kept in motion by a small centrifugal pump driven by an electric motor of 2 h.p. to 3 h.p. The pump takes the liquid from the lower vessel and forces it back into the upper vessel, in which three metallic plates (one for each rotor circuit), electrically insulated, are suspended (Fig. 7). The upper vessel has an overflow, and the plates are only immersed to a depth corresponding to the required resistance. By manipulating the starting lever, which works the reversing switch and closes the inductor circuit, a stop-valve, V_2, will be closed; the level of the liquid in the upper vessel will therefore rise, and the plates will be more and more immersed. The rate at which the water rises can be regulated by a cock on the inlet pipe. The maximum speed of the machine is reached when the liquid has risen up to a second overflow, which is always open, and which causes the liquid to overflow continually from the upper vessel into the lower one. The circulation of the liquid prevents it from getting heated. When the lever of the reversing switch has been pushed home, to the right or left, according to the direction in which the machine is to turn, it may be moved back through a certain angle without breaking the circuit. In doing this the stop-valve is gradually opened so that the water can run out again, and the speed will be reduced as desired. The circuit will not be broken until the lever is turned back into its vertical position; as the level of the liquid is falling steadily, the current, as well as the speed, of the motor will be gradually reduced; the interruption, therefore, will not be sudden. The immersion of the plates may be further limited by an overflow, V_1, so as to reduce the speed when persons are carried up and down. When the pit or the ropes are to be examined, the speed may be still further reduced by regulating V_1. The conditions, when using starting resistances, are very unfavourable to the electric brake; one cannot count on recovering the energy, but one must try to utilise the energy stored in the moving masses as much as possible, and to let the cage arrive at the mouth of the pit with a much reduced speed which will only require the brake for holding the cage. The intermittent working of haulage machinery and the increased energy wanted for starting a three-phase motor with the rheostat causes sudden and irregular demands on the generators at the power station. The latter machines are to be designed accordingly large enough and supplied with sufficiently heavy flywheels. If this is not the case, the result will be a fall of speed and voltage which will be felt all over the area of distribution; this is the case at Preussen, and even at the coal mines at Grand Hornu, where the generating plant comprises engines, one of 2,100 h.p. with 75 tons flywheel, and one of 4,200 with 100 tons flywheel. This engine is to be worked with three winding machines. Only one is at work at present with the 2,100-h.p. engine. The electrical energy delivered varies from 300 kw. to 900 kw., and the fall of voltage is about 10 per cent. Direct driving of winding machinery by asynchronous motors requires generators capable of standing a considerable overload, and the installation of very powerful sets at the power station. This means an increased expenditure for extra boilers, steam-engines, and alternators; but, on the other hand, the use of three-phase machines is much simpler and much less costly than transforming alternating currents into continuous currents.

Continuous-Current Motors.—The fundamental equations for continuous-current motors are (1):

$$i = \frac{E-e}{r} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$p = i\,e = i\,n\,N\,\Phi \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$c = \frac{i\,n\,\Phi}{2\,\pi} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

$$\omega^1 = 2\,\pi\,\frac{N}{60} = \frac{2\,\pi}{60}\left[\frac{n\,\Phi\,E - 2\,\pi\,r\,C}{n^2\,\Phi^2}\right] \quad . \quad (4)$$

$$\omega^1 = \frac{2\,\pi}{60} \times \frac{E - i\,r}{n\,\Phi} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

where i is the current passing through the armature;
E the difference of potential between the terminals;
e the counter E M F.;
r the resistance of the armature;
p the mechanical power given off;
n the number of inductors on the armature;
Φ the total number of magnetic lines through the armature;
N number of revolutions per minute;
ω^1 the angular velocity of the armature.

Shunt motors and separately excited motors possess somewhat similar properties, at least, when they are supplied at a constant difference of potential. In separately excited motors the flux, Φ, is constant, save for the slight reduction due to armature reaction. The torque (3) in this case is proportional to the current, i. When the motor is supplied with a constant current, its torque is also constant, and its speed (4) is proportional to the difference of potential between the brushes. By varying the difference of potential we could work the motor with a constant

Digitized by Google

torque at different speeds, provided that the current through the armature is kept constant. Under these circumstances the mechanical characteristic of the motor—*i.e.*, the curve which represents the torque as a function of the speed—will be a straight line parallel to the axis of abscissæ (Fig. 8). The machine may then be started with any desired torque by progressively increasing the difference of potential between the brushes. If we maintain the constant difference of potential, the current in the armature will always be strong enough to produce a torque which can overcome the resisting moment (3); the speed varies with the torque; when the torque is zero the speed will be

$$\omega^1 = \frac{2\pi}{60} \times \frac{E}{n\Phi}.$$

This is the maximum theoretical speed which the motor can attain when running with no load; the current in the armature is then zero, and the counter E.M.F. is equal to the difference of potential between the bushes. On account of the losses of energy due to hysteresis, eddy currents, and mechanical friction, the torque of the motor will become zero before the current and at a lower speed. When the resisting moment becomes negative, tending to drive the motor at a speed greater than $\omega^1 = \frac{2\pi}{60} \times \frac{E}{\Phi n}$, then the counter E.M.F., e, will be greater than E; the current in the armature will be reversed and will flow from the motor back into the mains; and the motor becomes a generator and acts as a brake by transforming the mechanical

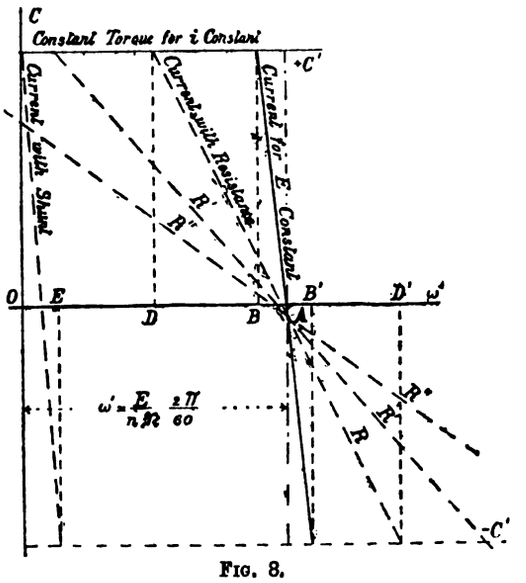

FIG. 8.

energy which it receives into electric energy. As soon as there is a resisting moment the speed will fall below $\frac{2\pi}{60} \times \frac{E}{n\Phi}$, and the current absorbed by the motor will be just sufficient to produce a torque equal to the resisting moment. The relation between ω' and C is represented by a straight line (4) passing through the point corresponding to $\omega^1 = \frac{2\pi}{60} \times \frac{E}{n\Phi}$, and inclined slightly towards the axis of ordinates (Fig. 8); the ohmic resistance of the armature, r, is small, and hence $\frac{2\pi r}{n^2\Phi^2}$ is also very small. The speed is therefore practically constant for all loads. It varies between the values O B and O B' for loads between + C' and − C' (Fig. 8). Separately excited motors supplied at constant difference of potential possess, therefore, the same self-regulating properties as three-phase motors. The same is the case with shunt motors, which behave, when supplied at a constant difference of potential, like separately excited motors. When a shunt motor is supplied at a constant voltage, the field current as well as the flux will be constant, and the motor will, therefore, behave like a separately excited machine. It is, however, not always possible to keep the flux constant; for instance, when starting the motor, the mains will be almost short circuited through the armature, whose resistance is very small, and this causes a momentary fall of potential across the terminals, resulting in the field current, and, therefore, also the flux, being reduced. For this reason a resistance must be inserted in the armature circuit to prevent the armature current from exceeding three or four times its normal strength. The field current, and, therefore, also the flux, will remain constant, as they are not affected by the resistance. We now reduce the resistance gradually, as the speed of the motor and, therefore, also the counter E M.F. increase, and in this manner a constant armature current as well as a constant torque may be maintained. Under these conditions a shunt motor will behave like a separately excited machine supplied with a constant current. Continuous-current motors may be started without much loss of energy, and we will now examine the different methods which have been used for this purpose.

1. *Starting Rheostat.*—This method is used when a shunt motor is connected across a pair of mains between which a constant difference of potential is maintained. A buffer battery may also be inserted across the same mains. The field current is thus constant. A variable resistance, R, is inserted in series with the armature. If the difference of potential between the brushes be E^1, the power absorbed in the resistance will be $(E - E^1)\ i = i^2 R$. During the period of acceleration, the resistance, R, is reduced progressively and the current, i, and, therefore, also the torque, C, may be kept constant; this requires that $E^1 - e$ must also be kept constant. The speed cannot be kept quite constant independent of the load with the resistance, R, inserted. This resistance increases the ohmic resistance of the armature. The relation between the torque, C, and the speed (4) will be found by substituting $r + R$ for r. This relation is represented by a straight line through the point corresponding to $\omega^1 = \frac{2\pi}{60} \times \frac{E}{n\Phi}$, and the inclination of the line towards the axis of ordinates will be the greater, the greater R is. The straight lines, A R, A R', A R'', etc. (Fig. 8), which correspond to increasing values of R, show that the greater the resistance is the more will the speed increase in proportion to the torque. This method of starting a shunt motor causes the same loss of energy as we found with three-phase motors.

2. *Series-Parallel Method.*—When using two motors for driving the winding machinery, the starting may be done by the series-parallel method, the same as used for regulating the speed of electric tramcars. It consists in starting the two motors by connecting them in series; the difference of potential across each armature, if no resistance is inserted, will be $\frac{E}{2}$. The normal speed will thus be reduced to half; when later on the motors are connected in parallel and the total difference of potential, E, is applied across the armature, the full speed will be attained. For the purpose of preventing jerks, while switching over from series to parallel, a kind of rheostat (controller) must be used. This method of starting gives a more satisfactory efficiency than the preceding methods, but the two motors together cost more than one motor of the same total power, and the circuit controller is complicated. This principle has been adopted by Messrs. Siemens and Halske at the Thiederhall Mines, at Thiede, near Brunswick. By using electric sources with variable pressure, the voltage between the brushes may be varied. For this purpose we may either use a battery of accumulators split up into sections, or a special generator, or an auxiliary dynamo.

3. *Batteries in Sections.*—A battery of accumulators, which is inserted across the mains, is split up into sections; the latter are, however, connected in series so as to make up a total voltage equal to the pressures between the mains. During the period of acceleration the brushes of the motor are connected across one or more sections of the battery, the number of sections being increased as the speed of the motor rises; the normal speed will be attained when all the sections are switched on. The motor may be reversed by reversing the connections between the brushes and the poles of the battery (the current in the armature will thus be reversed), and the different sections of the

Digitized by Google

battery will then be equally discharged, provided that their number is even. The motor will have as many normal speeds as there are sections—for instance, four sections will give normal speeds equal to quarter, half, three-quarters, and full speed. For the purpose of avoiding jerks when switching a new section into the motor circuit, a rheostat must be used. The total resistance, R, required for each battery section must be equal to the resistance of the armature; R is, however, subdivided into smaller resistances, which are cut out progressively as the speed of the motor increases. The economy of the system as compared with that of the armature rheostat is only obtained by great complications, which was shown only too clearly in the case of the winding machine at pit No. II. Zollern, installed by Messrs. Siemens and Halske.

4. *Special Generator.*—In this system the haulage motor is separately excited by a constant current, and the difference of potential is varied, and therefore also the speed, by regulating the E M F. of the generator which supplies the motor by means of a field rheostat; the loss of energy is almost nil. But as one cannot use a buffer battery, the generator must be able to stand all the variation of the load, and the engine which drives the generator will be running on no load during the stoppages. The work of the engine might be equalised by providing it with a large flywheel, which could store up the energy during the stoppages of the haulage machines, or the engine might drive another generator, which, in connection with a buffer battery, could supply a circuit at constant pressure. It is, however, always necessary to have reserve sets at the power station, and this makes the undertaking costly. The use of a special generator is not practical unless the haulage machinery is close to the supply station This system has been adopted by the Allgemeine Elektricitäts-Gesellschaft in 1895 at the Hollertzug mines, and recently for two machines at the Alexandre pits of the Arnim Collieries at Planitz, near Zwickau, in Saxony. The system of a special generator may be worked more economically by adopting high-tension three-phase currents. In this case, the special generator is driven by an asynchronous motor, and the two machines are installed close to the haulage machinery; by using high-tension currents, the distance from the power station is not of much importance.

(To be continued.)

OLDHAM ELECTRICITY ACCOUNTS.

The accounts of the Oldham Corporation electricity department for the year ended March 25, 1905, show a total expenditure on capital account to that date of £269,155. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc, are appended.

General Balance Sheet.

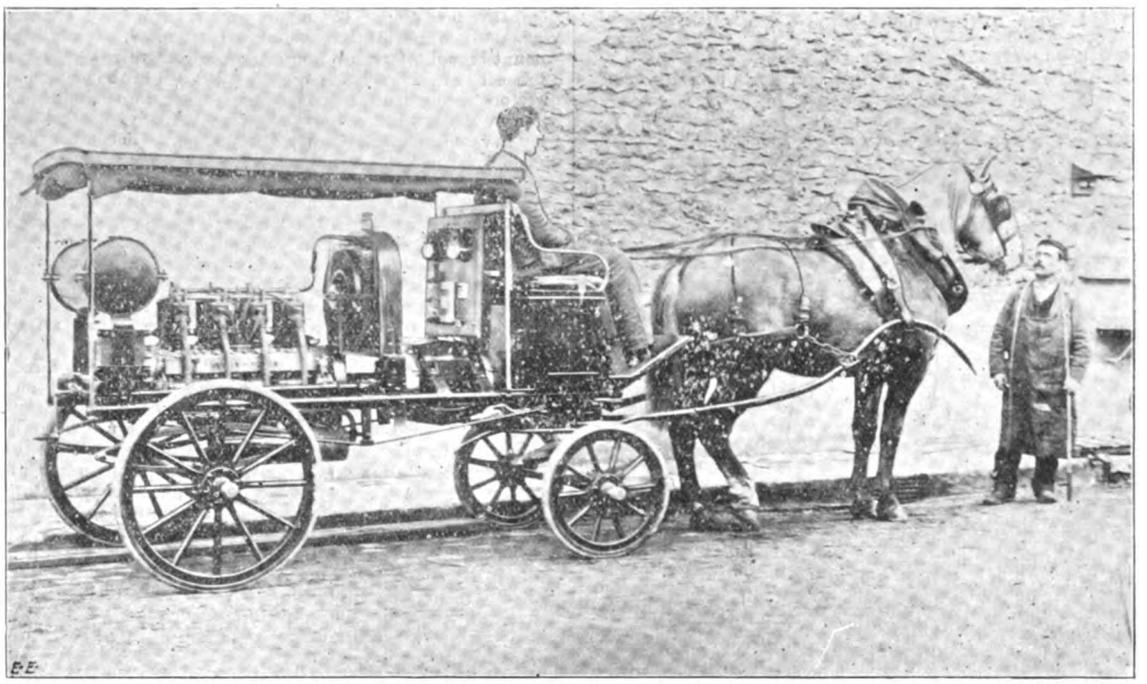
TRADE NOTICES AND NOVELTIES.

A Useful Motor-Dynamo Combination.

Through the courtesy of De Dion Bouton Limited, 10, Great Marlborough-street, Regent-street, W., we are able to illustrate herewith one of their compact motor-dynamo combinations. This is a 15-h.p. four-cylinder plant, replete with water and petrol tanks, radiator, fan and switchboard, and mounted on a horse-drawn vehicle made with tubular frame. The whole forms

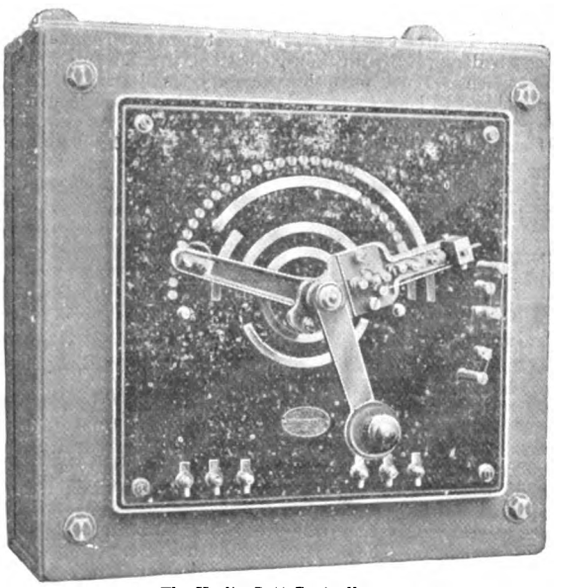


De Dion Bouton Portable Motor-Dynamo Combination.

a self-contained portable electric power installation developing 10 kw., specially suitable for use in connection with military work, travelling exhibitions, etc. The dynamo is specially light, aluminium parts being used wherever practicable. An electric department, where dynamos, motors, accumulators, dry batteries, etc., are made forms an important portion of the De Dion Bouton factory, a large demand being experienced, we understand, for motor-dynamo combinations for lighting country houses, motor-propelled vehicles, etc.

A New Controller.

Accompanying is an illustration of a new controller—the Verity-Gott—which Messrs. Veritys Limited, Deansgate, Manchester, are putting on the market. These controllers are

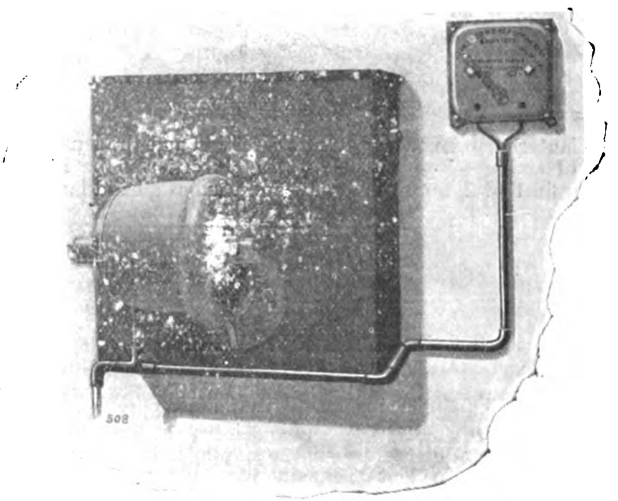


The Verity-Gott Controller.

made either for obtaining a long range of speed by supplying a motor with two voltages, or may similarly be used with series-parallel machines. They are particularly suitable for fine adjustment in the speed of boiler-feed pumps, machine tools, printing machines, etc. They give, it is claimed, a uniform increase of speed throughout a long range, and there is no excessive sparking at the change-over point. Both armature and field regulation on both voltages is provided, the change from one to the other being performed imperceptibly by the continuous rotation of the hand lever. The controllers are usually designed to give about 60 different speeds. A test recently made on a 30-h.p. motor gave the following actual speeds with the armatures in parallel: 180, 200, 230, 240, 250, 260, 270, 285, 300, 305. At the figure 305 the controller brought the armatures into parallel, and the speed then registered was 308, practically the same as the final speed on the series connections. The speeds then advanced in the same regular increments until the maximum speed (616) was reached. During the test there was no flashing at the brushes of the motor, or jumping in speed when changing from series to parallel or *vice versâ*, which operations were repeatedly carried out.

Electric Blower.

We note that James Keith and Blackman Company, Limited, 27, Farringdon-avenue, E.C., now supply a useful electric motor and blower combination for application to smiths' fires, furnaces, etc. The present system, it is pointed out, of arranging a smith's shop with one large blower for all the fires is very inefficient. The blower has to be large enough to blow all the fires at once, and to give the highest pressure required at any time on any fire, with additional pressure for blowing through a length of air-pipe. In consequence the power required to



Electric Motor-Blower Combina n

drive the blower is very heavy, and remains heavy even when a large proportion of the fires are shut off; also any repairs to the blower, motor, or engine driving means shutting down the entire shop. To meet these and other objections, the combination under notice has been designed for fitting direct to the tuyer of each forge. The power required is very small

Digitized by Google

being from 100 watts for light work to 300 watts for heavy work, and as no power is used when the fire is not being blown, the average power will be from 50 per cent. to 33 per cent. of above. Moreover, the blast being started, stopped, and controlled by a switch, is under much better control than when regulated by a valve. The general form of the apparatus is shown by the accompanying illustration. One casting forms the casing of the blower and the field of the motor. The air propeller is of aluminium, and the weight of the revolving part is very small. The motor is series wound to run at a speed of 600 r.p.m., and it will stand switching directly on to full speed without injury.

The "University" Lamp.

Credit must be given to Messrs. Mayer and Meltzer, 71, Great Portland-street, W., for the introduction of many useful

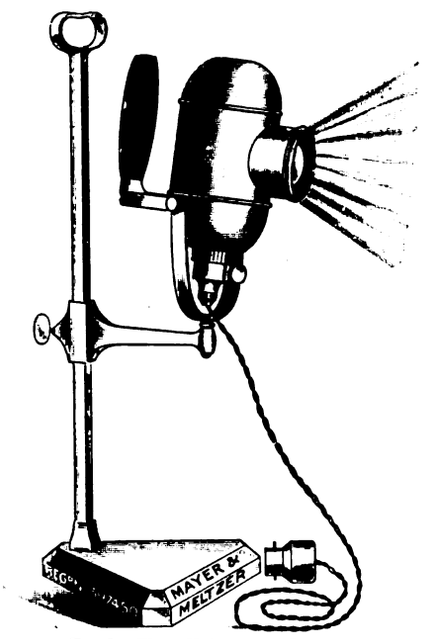


FIG. 1.—The "University" Lamp.

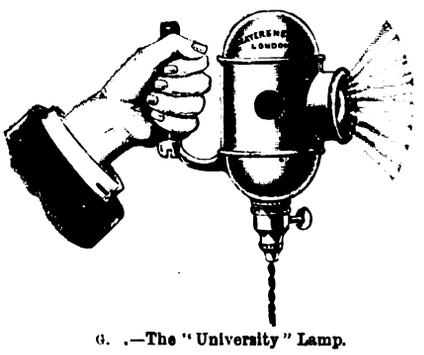
appliances for medical work. One of particular interest to us is their "University" examination lamp for hospital use and the consulting-room. This lamp, which we illustrate in Fig. 1, shows a clear disc of light without any image of the filament.



G. .—The "University" Lamp.

The lantern can be turned in any direction and the lens thrown out of action for ophthalmic work. It can also be lifted, as shown in Fig. 2, out of its cradle and used as a hand lamp.

LEGAL INTELLIGENCE.

UNDERGROUND WIRES.

Mr. Paul Taylor on Wednesday sat as arbitrator in a dispute between the Postmaster-General and the Borough Council of St. Marylebone in reference to the payment of certain costs incurred by the Council in making good certain roadways in their district, which had been broken up by the postal authorities for the purpose of laying underground telegraph wires. The Post Office authorities had applied for permission to lay down other wires, but this had been refused by the Borough Council pending the settlement of the latter's claim. The Postmaster-General thereupon availed himself of the powers conferred on him by the Telegraphs Act of 1878, and the disputed point was referred to Mr. Paul Taylor.

Sir Robert Hunter represented the Postmaster-General, and Mr. Bodkin appeared for the Borough Council.

Mr. Paul Taylor decided that the wayleaves applied for by the Postmaster-General ought to be granted by the Council, irrespective of any dispute as to the cost of previous operations. He also pronounced in favour of the Postmaster-General's claim in respect of the proposed erection of a pole for telegraphic purposes just outside Lord's cricket ground.

COMPANIES' MEETINGS AND REPORTS

BRITISH ELECTRIC TRACTION.

The ninth ordinary general meeting of the shareholders was held on Monday, Sir Charles Rivers Wilson, G.C.M.G., C.B., chairman of the Company, presiding. The report and statement of accounts for the year ended March 31 last, which were adopted, showed, omitting the amount brought forward from the preceding year, a net profit for the 12 months of £239,027, as against £219,818 in the previous year. The directors recommended the payment of the same dividend upon the ordinary shares as in the previous year—namely, 6 per cent.—although they have had to pay nearly £15,000 more debenture interest, and about £900 more dividend on preference share capital. This left £16,000 to be carried forward, as against £33,000 in the preceding year. The dividends and interest received upon investments amounted to £146,163, or about £10,000 more; but the investments amounted to £237,000 more. The balance-sheet shows a large reduction of liabilities. Last year the Company owed their bankers in respect of temporary loans sums amounting to £200,000, and they had had deposited with them by associated companies the total sum of £65,000. The whole of the loans have been repaid, and the deposits have been reduced to £19,250. The amounts due from associated companies have been reduced during the past year from £1,116,361 to £782,325.

The CHAIRMAN said satisfactory arrangements had been made for guaranteeing to the Bombay Tramways and Electricity Co. £600,000 of preference capital and £600,000 of debenture capital, and the transfer to the new company would be completed within this month. The Metropolitan Electric Tramways Co. was progressing favourably in the development of the tramway and light railway enterprise in the northern suburbs of London, and also in connection with the electric power supply business which was now controlled by the Metropolitan Tramways Co. The Company's Power Act covered over 300 square miles in Middlesex, Hertfordshire, and Essex, a district which would probably in the near future show a very considerable development for industrial purposes. The directors thought that well-designed electrical tramway undertakings had nothing whatever to fear from competition by motor omnibuses.

Mr. J. CHARTIER was of opinion that the dividend had not been fully earned, and he was surprised, he said, that the directors took £200,337 worth of consols at an average of over 98 per cent. He moved an amendment to reduce the dividend from 6 per cent. to 2 per cent.

The CHAIRMAN said that they had earned the dividend, and something more, enabling them to make a substantial carry forward.

The amendment was not seconded, and the report was adopted.

Sir Charles Rivers Wilson was re-elected a director of the Company.

GENERAL ELECTRIC.

The ordinary general meeting was held on Monday, Mr. G. Byng (the chairman of the Company) presiding, when the report, given in our last issue, was adopted.

The CHAIRMAN said they had received a fair amount of orders for large machines, such as contracts for Cardiff, South London, Woolwich, Fulham, Manchester, and Dublin. As regards the latter, the new 1,500-kw. set supplied during last year had turned out a great success, whilst the old contract had at last been satisfactorily completed. The Company had supplied with their generators, through sub-contractors, engines which did not pass the necessary tests, and, as main contractors, they had been compelled to undertake the reconstruction of these engines, and the plant had been taken over. As regards other manufactures, such as telephones and bells, electric light fixtures and accessories, there had been increasing output, but generally with lower prices and more difficult to sell. The payment of a dividend at the rate of 5 per cent. for the year was agreed to.

The retiring director, Mr. H. Bevis, was re-elected, and a vote of thanks to the chairman and directors concluded the meeting.

NATIONAL TELEPHONE.

The thirty-sixth ordinary general meeting of the National Telephone Co. was held yesterday week at Hamilton House, E.C., Sir Henry Fowler, M.P. (the president), in the chair.

The CHAIRMAN said that the last half-year had been a satisfactory one. The income had amounted to £1,086,507, against £985,274 in the corresponding half-year of 1904. The Post Office royalty was over £100,000. The working expenses during the half-year had been £630,251, as against £563,060 twelve months ago, which left a profit of £355,618, as against £331,472, showing a net increase of £24,146 in the half-year; adding the sum brought forward, an available sum of £365,759 remained. The debenture and other interests were £97,143. The directors proposed to pay the same dividends as before on the preference shares and preferred and deferred stocks, which will absorb £148,917, and to carry to reserve £110,000. The capital expenditure during the half-year had been increased. They had spent on construction of exchange and private stations and upon other capital expenditure during the half-year £477,156, on land and buildings about £6,000, or a total of £534,320. The staff had increased from 12,902 to 14,647, and the unexecuted orders from 9,706 to 10,842. The business was rapidly outstripping

Digitized by Google

their available capital. The number of telephone message in 1904 over the system recorded in the usual way had been 995,671,664, or 10 times the number of inland telegrams in Great Britain and Ireland during that period. The average receipt by the Company for those messages was 0·43d.

The report was adopted, and the dividends declared for the six months ended June 30 as follows: 6 per cent. per annum on the first and second preference shares, 5 per cent. per annum on the third preference shares, 6 per cent per annum on the preferred stock, and 5 per cent. on the deferred stock.

The retiring directors (Mr. Charles Swain Agnew, the Right Hon. Lord Harris, Mr. George Hunter Robertson, and Sir Albert Kaye Rollit, M.P.) were re-elected.

LISBON ELECTRIC TRAMWAYS.

The ordinary general meeting of the shareholders of the Lisbon Electric Tramways was held on Wednesday. Mr. Ludwig Breitmeyer presided in the absence of Sir Charles Euan-Smith.

The CHAIRMAN said that the favourable forecast of their chairman at the last annual meeting had been amply fulfilled. They had carried 3,000,000 more passengers, their cars had covered some 700,000 more car miles, and yet the cost of running the power-house remained at the same figure as before. The usual necessary provision of £20,000 for depreciation had been made, bringing this account to £40,000. The directors had also created a special reserve accident account, and a reserve account against the fluctuations of the exchange, with £10,000 and £5,000 respectively. After providing these sums, and paying the 6 per cent. dividend on the preference shares, the balance on hand amounted to £17,197, which sum it was proposed to carry forward to next year's accounts.

The report was adopted.

A motion was subsequently passed removing Mr. Alfred Parrish from the board of directors.

EAST LONDON RAILWAY.

Lord Claud Hamilton presided at Tuesday's meeting of the shareholders. He said that in the future the East London line would have to be electrified, but he thought they had done well to wait and see the results of experiments on other lines. In this they had followed the example of the Great Eastern Co., whose directors felt that there had not been sufficient experience to enable them to judge whether the best system of electrification had yet been found. Both were poor companies, and could not afford to risk expenditure until this had been settled.

NERNST ELECTRIC LIGHT.

At a meeting of the shareholders on Monday a resolution for a sale of the Company's patent rights for Nernst lamps, as well as the right to the British royalties, to the Allgemeine Elektricitäts-Gesellschaft for the price of £24,000 was passed. The resolution will have to be confirmed at a subsequent meeting, but we understand that there is every possibility of it being carried into effect.

BARCELONA TRAMWAYS.

An extraordinary general meeting of the Company was held on the 21st inst., Mr. J. B. Concanon in the chair. An agreement between the Company and the Société Financière de Transports et d'Enterprises Industrielles, Brussels, for the sale of the Company's undertaking, was confirmed. It was stated that ordinary shareholders will receive at least £14. 10s. per share.

DIRECT UNITED STATES CABLE.

The fifty-sixth ordinary general meeting was held on Tuesday at Winchester House. Mr. E. M. Underdown, K.C., presided. The report (given in our last issue) was adopted, and the payment of the dividend and bonus mentioned, both free of income tax, making, with the three interim dividends already paid, a total distribution of 3¼ per cent. for the year ended the 30th ult., was agreed to.

DEUTSCHE-UBERSEEISCHE ELEKTRICITAETS-GESELLSCHAFT.

Dr. Salomonsohn presided at the meeting on July 18 at Berlin. A resolution was passed practically doubling the capital of the Company to £7,050,000 in order to purchase the Chilian Electric Tramway and Light Co. at Santiago. The Company will receive in exchange for 9,768,000 marks in stock £598,738 in 6 per cent. preference shares of the Chilian Co. quoted at 80 per cent., and, in addition, £386,000 in ordinary shares of the same company gratis. Mr. Ludwig Breitmeyer, a partner of Messrs. Wernher Beit and Co., was elected a member of the Board of supervision.

EASTERN TELEGRAPH.

The report for the six months ended March 31 shows a revenue of £676,256. Deducting £179,330 for the ordinary expenses and £53,253 for expenditure relating to maintenance of cables, depreciation of spare cable, and income tax payable abroad, a balance of £443,662 remains, to which is added £35,631 brought from the preceding half-year, making a total available balance of £479,294. After providing for income tax payable in England, interest on loan, etc., and for two quarterly dividends on the preference stock, there remains a balance of £386,147, out of which £10,000 has been placed to the reserve fund for maintenance ships, £195,000 to the general reserve fund, and an interim dividend of 1¼ per cent. on the ordinary stock, amounting to £50,000, has been paid. The directors now recommend a final dividend on the ordinary stock for the year ended March 31, 1905, of 1¼ per cent., and a bonus of 2 per cent., amounting together to £130,000, free of income tax, and making, with the three previous payments on account, a total distribution of 7 per cent. for the year. It is proposed to carry forward the balance of £1,147 to the next account. As the receipts from Indian traffic for the three years ended June 30, 1905, have reached the average "standard revenue" stipulated for under the guarantee agreement with the Indian Government, it had been decided to reduce the rate between Europe and India from 2s. 6d. to 2s. per word, which reduction will be brought into operation on Aug. 1, and from the same date the tariff between Great Britain and Aden will be reduced from 2s. 6d. to 2s. per word. An arrangement has also been concluded with the Egyptian Telegraph Administration for a reduction of tariff between Europe and Egypt (1st Region) from 1s. 5d. to 1s. per word, which will also come into operation on Aug. 1.

The sixty-sixth half-yearly ordinary general meeting was held on Wednesday, Sir John Wolfe Barry, K.C.B., in the chair. The report was adopted.

CITY AND SOUTH LONDON RAILWAY.

The report for the half-year ended June 30, 1905, shows receipts from all sources amounting to £76,164, the cost of working was £35,134, leaving a profit of £41,030. Adding the balance brought forward, the net revenue account totals £42,924. After providing for debenture stock interest, and transfer to renewal fund, a balance of £30,199 remains available for dividend. The directors recommend a dividend of 5 per cent. per annum on the preference stocks (1891, 1896, and 1901), and a dividend at the rate of 2 per cent. per annum on the consolidated ordinary stock for the half-year, leaving a balance of £1,041 to be carried forward. The number of passengers (exclusive of season-ticket holders) carried during the period was 8,662,588, a decrease of 561,399; receipts (including season tickets) totalled £71,802, a decline of £4,585. The dry weather and the competition of the London County Council electric tramways has, it is stated, adversely affected the traffic. The directors determined in May last to make a considerable reduction in the fares charged on the railway to meet the London County Council competition, and an increase of passengers has taken place, but not sufficient so far to do more than compensate for the reduction made. The contract for the construction of the extension to Euston was let in March last, and the sites for the stations have all been acquired, the shafts for the lifts are down to their full depth and the tunnels have been commenced. The directors hope that the line will be opened for traffic before the end of next year.

BUENOS AYRES AND BELGRANO ELECTRIC TRAMWAYS.

The result of the working for the half-year ended June 30 last is as stated: receipts, £86,400, against £85,096 in 1904; and expenses, £51,500, against £45,624. Adding the amount brought forward (£2,085), the balance available is £36,986. The increased expenditure is due partly to the higher wages bill and partly to exceptional repairs to rolling-stock, etc. After allowing for interest on debenture stocks, preference dividends, and setting aside £4,000 to meet the half-year's contributions to the renewals fund, debenture sinking fund, and accidents insurance fund on the same scale as those made in 1904, a balance of £10,239 remains, allowing for the payment of the same interim dividend as last year (1s. 6d. per share), with a carry forward of £2,739. Considering the uncertainty as to the effect on the Company's traffic of the approaching electrification of directly competing lines, the directors have decided not to pay a dividend until after the final accounts for the year have been completed.

DISTRICT RAILWAY.

The report for the half-year ended June 30 last shows the total receipts for the half-year have been £206,601, against £212,771 for the corresponding half of 1904, or a decrease of £6,169. The working expenses have been £114,879, against £115,155 for the corresponding half of 1904, being a decrease of £276. The revenue account shows a profit of £91,722, against £97,615 earned in the corresponding half of 1904, being a decrease of £5,893. The report says the work of electrification is now practically completed. The power-house is in working order. The sub-stations are completed, and the whole of the cables are laid throughout the Company's system. Electric trains are now running between Ealing and Whitechapel, and from Harrow to Mill Hill Park, and from Hounslow to South Acton. A service is also running between High-street, Kensington, and Putney. Further electric trains will from time to time, as cars are delivered, be brought into running into substitution for the steam service. Satisfactory progress has been made with the reconstruction of the new stations at High-street, Kensington, and South Kensington. The widening of the Company's line between West Kensington and Hammersmith is practically finished, and an arrangement has been made to grant to the Great Northern, Piccadilly, and Brompton Railway Co. a joint user of such widened lines at a yearly

Digitized by Google

rental of £12,000 as from Jan. 1 last. The car-sheds and repairing shops at Mill Hill Park are completed. Extensive sidings have been laid down at Mill Hill Park and Gloucester-road. An arrangement, which it is believed will be for the mutual advantage of both companies, has been made with the Great Western Railway Co. for the construction of an interchange station at Ealing. With a view to provide the balance of the moneys required for electrical equipment and to meet other obligations, it is proposed to sell surplus freehold lands and properties of the Company to the value of £250,000. The directors propose to form a surplus land company, the capital of which will, in the first instance, be offered to the shareholders. Since the last meeting Mr. C. A. Spofford has retired from the Board, and the Right Hon. Lord George Hamilton, M.P., and Mr. W. H. Brown have been elected directors.

CENTRAL LONDON RAILWAY.

The report for the half-year ended June 30 shows receipts from all sources amounting to £185,876, an increase of £915, and the working expenses to £95,674, an increase of £549, leaving a balance of £90,202. The number of passengers increased by 68,038, and the number to whom cheap return tickets were issued, workmen and others, was 3,051,196, a decrease of 30,174. The average receipt per passenger was 1·86d., the same as in the half-year ended June, 1904. After providing for interest on debenture stock, etc., a balance of £94,886 remains, including £22,112 brought forward. The directors recommend dividends on the undivided ordinary and on the preferred ordinary stock at the rate of 4 per cent. per annum. After reserving £10,606 the proportion of dividend applicable to the deferred stock, which is not payable until the result of the year's working has been ascertained, there remains £34,886 to be carried forward.

BAKER STREET AND WATERLOO RAILWAY.

The accounts of the Company to June 30 show that during the half-year the capital expenditure amounted to £367,189. The estimated expenditure for the current half-year is £600,000. In view of all the circumstances, the progress made with the works during the half-year had been satisfactory. The Company's Bill, which was before the shareholders at the Wharncliffe meeting in February last, has passed through the committees of both Houses of Parliament.

LIVERPOOL OVERHEAD RAILWAY.

The accounts for the past half-year show a balance of £7,883, out of which the directors recommend the payment of the preference dividend, but nothing on the ordinary shares, leaving £4,336 to be carried forward. A year ago the ordinary shares received 1¼ per cent. per annum and £4,052 was then carried forward.

DUNDEE TRAMWAY AND CARRIAGE.

The last report notes a considerable diminution in the receipts of the Company, but owing to all-round economy the net profit is not much under the previous year's. The revenue amounted to £10,087 and expenditure to £8,227, making the net profit £1,860. An interim dividend of 1s. 6d. per share was paid in December, and a similar dividend is now recommended, making 7½ per cent. for the year. It is recommended that £500 be placed to contingent fund, making it £4,000, and that £270 be carried forward.

CHILIAN ELECTRIC TRAMWAY AND LIGHT.

The last report shows a net balance of £23,289, to which must be added the sum brought forward, £1,621. It is proposed to pay a dividend on the preference shares at the rate of 2 per cent., leaving £12,911 to be carried forward. The electric lighting department earned a net profit of 276,597dol. during last year, against 179,723dol. earned in the year 1903. The tramways earned 678,197dol., against 232,857dol.

DUBLIN UNITED TRAMWAYS.

The report for the half-year ended June 30, submitted at the ordinary meeting on 25th inst., showed a profit of £45,355, out of which it is proposed to pay a dividend for the half-year at the rate of 6 per cent. per annum, free of income tax, on the ordinary shares, leaving £5,000 to be added to the reserve fund and £5,255 to be carried to next account. Extensions of the tramways from Rathmines to Dartry-road and from Dolphin's Barn to Rialto Bridge, South Circular-road, were opened for traffic during the half-year.

BLACKPOOL ELECTRIC TRAMWAYS (SOUTH).

It will be remembered that at an extraordinary general meeting of the shareholders of the Blackpool Electric Tramways (South), at the beginning of this month, resolutions were passed that the Company be wound up voluntarily, and that the shares held in the Blackpool, St. Annes, and Lytham Tramways Co. be divided among the shareholders. The debenture holders object to this proposal. At a meeting of shareholders on Monday it was decided not to proceed at present with the winding up of the Company and the appointment of a liquidator.

NEW COMPANIES REGISTERED.

City and Suburban Motor Omnibus Co., Limited.—Capital, £10,000. Object: to carry on the business of motor omnibus proprietors, etc.

J. K. Conway and Co., Limited.—Capital, £1,000. Object: to carry on the business of dealers in gas and electrical appliances, fittings, accessories, and materials, machinery manufacturers, etc.

De Forest Wireless Telegraph Syndicate.—Capital, £120,000. Object: to adopt an agreement with S. S. Bojesen, and to carry on the business of owners of wireless and other telegraph systems, patents, and concessions, etc.

Peterborough Motor 'Bus Company, Limited.—Capital, £5,000 in £1 shares. Object: to carry on the business of proprietors of motor omnibuses, other public or private conveyances of all kinds. Registered office: 4, Orcas-street, Peterborough.

Chemin de fer Electrique d'Ostende-Blankenberghe et Extensions.—Registered at Brussels. Capital in 5,000 preference shares at £20 each, 25,000 ordinary, value not stated. Object: construction of electric tramway from d'Ostende-Blankenberghe.

Southend-on-Sea and District Motor Omnibus Co., Limited.—Capital, £10,000. Object: to carry on the business of proprietors of motor omnibuses and other public or private conveyances of all kinds. Registered office: 105, Broadway High-street, Southend-on-Sea.

Yates and Thom, Limited.—Capital, £240,000 in £1 shares. Object: to acquire and carry on the business as Yates and Thom of ironfounders, boiler makers, mechanical and electrical engineers, machine and tool manufacturers, etc. Registered office: Canal Engineering Works, Blackburn.

Bruné-Turchi Telegraphic Co., Limited.—Capital, £30,000. Object: to acquire inventions or rights relating to telegraphic or telephonic processes or instruments, or to the production, treatment, storage, application, distribution, and use of electricity, in particular; to acquire certain inventions and patents owned by E. Bruné and C. Turchi relating to simultaneous telephony and telegraphy, etc. Registered office: 31, Lombard-street, E.C.

Liens Registered.

Kent Electric Power Syndicate, Limited, London, E.C.—Charge registered, July 18, for £750. Secured on the undertaking and all the assets, present and future, including any uncalled or unpaid capital.

New General Traction Co., Limited, Westminster.—Particulars registered July 15, under Sub-section 4, Section 14, of the Companies' Act, 1900, relating to a series of 5 per cent. debentures, created Feb. 8, 1905, for £18,700. Trustees: Captain F. Pavey, Foley House, Portland-place, W., and Baron Emile B. d'Erlanger, 20, Bishopsgate-street Within, E.C. Charged on 19,070 fully-paid shares of £10 each in the Norwich Electric Tramways Co., 10,267 fully-paid shares of £10 each in the Coventry Electric Tramways Co., 12,262 fully-paid preference shares of £1 each in the Douglas Southern Electric Tramways, Limited, and by way of floating charge on the assets, present and future, other than the above-mentioned property.

United Electric Tramways of Monte Video, Limited.—A trust deed, dated July 12, 1905, to secure £500,000 debenture stock, created Oct. 28, 1904, has been registered. Property charged—90 debentures of 4,700dol. gold each, and 560 fully-paid shares of 1,000dol. gold each, in La Sociedad Comercial de Monte Video, any debt that may be incurred by the said company to this company in respect of moneys advanced to them out of the proceeds of the debenture stock of this company, issued or to be issued, in accordance with the terms of the said trust deed, etc. Trustees: Major W. E. E. Gordon, M.P., 4, Chelsea-embankment, S.W.; the Hon. C. G. Hay, M.P., Basildon House, Moorgate-street, E.C.; and H. A. Trotter, 7, Mincing-lane, E.C.

APPOINTMENTS VACANT.

Engineer-in-Charge, Bermondsey. Salary, £2.

Assistant Engineer about 25 years of age, with good knowledge of mechanical engineering. Applications to G M 532, Messrs. Deacon's, Leadenhall-street, London, E.C. See advertisement in last issue.

Practical Engineer to supervise the equipment of a complete electrical tramway in India. Applications to Box No. K 10, *Electrical Engineer* Office. See advertisement in last issue.

Assistant Buyer in electrical engineering works in Midlands. Applications to Box G 49, *Electrical Engineer* Office. See advertisement in last issue.

Youth (smart). Applications to the Electrical Co., 121-125, Charing Cross-road, W.C. See advertisement in last issue.

Mechanical and Electrical Engineer. Salary, 30s. per week. Applications to R. N., *Electrical Engineer* Office.

Junior Assistant Electrical Engineer, Burnley electricity works. Salary, £119. 12s. per annum. See advertisement.

Pupil, Stratford Urban District Council electricity department. See advertisement.

Chief Draughtsman, also Assistant Draughtsman. Applications to T. K., care of Davies and Co., advertising agents, Finch-lane, Cornhill. See advertisement.

Premium Pupil. Applications to Electricity Works, Canterbury. See advertisement.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Warrington. — Tenders are required for cables. Tenders by Aug. 11.

Florianopolis (Brazil).—The Municipality require tenders for the lighting of the town by Oct. 2.

Turnu-Severin (Roumania).—The Mayor invites tenders for the electric lighting of the town. Tenders by Sept. 10.

Olympia 1905 Exhibition.—The Executive Committee invite tenders for the loan or hire of 300-kw. direct-coupled steam set.

Brussels.—The Government Telegraph Department require tenders for 14,700 pine telegraph poles. Specification 76 may be obtained from their office at Brussels. Tenders by Aug. 9.

Paris.—The Post and Telegraphs Department require tenders for tubes for telephone and telegraph cables. Specifications from the above office, First Bureaux, 103, Rue de Grenelle. Tenders by Aug. 7.

Alicante (Spain).—The Harbour Board (Junta des Obras del Puerto) require tenders for two electric cranes, capable of lifting 10,000 ko. and 1,500 ko. respectively. Tenders by Sept. 15. Estimate, 107,010·10 pesetas.

Calanas (Spain).—The Municipality require tenders for the installation and working for 10 years from Jan. 1, 1906, of the electric lighting of the town. Tenders by July 27 to the Alcalde of Calanas, province of Huelva, Spain.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

Merthyr Tydfil.—Tenders are invited by the Urban District Council for the erection of refuse destructor plant capable of effectually burning 120 tons of refuse per day, together with all buildings and contingent works connected therewith. Tenders by Sept. 1.

Ebbw Vale (Mon.).—Tenders are invited for the following, for the Ebbw Vale Urban District Council: (Section A) cables; (B) overhead lines; (C) street lamps and fittings; (D) meters. Specifications, etc., may be obtained at the offices of the consulting engineer, Mr. Reginald P. Wilson, 66, Victoria-street, Westminster. Tenders to the Clerk of the Ebbw Vale Urban District Council by 12 noon on Aug. 5.

Erdington.—Tenders are required for the construction of Section No. 1 of the Erdington tramways, comprising the laying of the permanent way, including copper bonding, wood block paving, and other works incidental to the laying of about 2¼ miles of double-track tramway, for the Tramway Committee. Tenders to the joint engineers, Mr. Robert Green (of Messrs. Pritchard, Green, and Co.), of 37, Waterloo-street, Birmingham, and Mr. Herbert H. Humphries, engineer to the Council, Public Hall, Erdington.

Municipal Board of Mussoorie (India).—The Municipal Board invite tenders for the supply, delivery, and erection at sites, in complete working order, of the following plant: (*a*) steel power pipes; (*b*) water-motors; (*c*) alternators with exciters; (*d*) switchboards with instruments and apparatus; (*e*) transformers; (*f*) induction motors; (*g*) pumps; (*h*) workshop machines. Also for the supply and delivery of the following: (*a*) bare copper wire for overhead mains; (*b*) insulators and lightning arresters; (*c*) arc and incandescent lamps; (*d*) telephone equipment; (*e*) workshop tools; (*f*) general stores. Specifications, form of tender, and general conditions can be obtained on application to Mr. C. H. Shanan, municipal electrical engineer, Municipal Office, Mussoorie, India (telegraphic address, Shanan, Mussoorie), on payment of a deposit of Rs.75 (£5), which amount will be returned on receipt of a bona fide tender. Tenders by Oct. 23. See advertisement.

RESULTS OF TENDERS.

Watford.—The tender of Babcock and Wilcox, at £41, has been accepted for chequer plating at the electricity works.

Hampstead.—The tender of the St. Helen's Cable Co. has been accepted for the supply of high-tension, three-core house service and single cable for 12 months from Aug. 1.

Hackney.—The Borough Council have accepted the tender of Messrs. Le Grand and Sutcliff, of 125, Bunhill-row, London, E.C., for an artesian well and air-lift pumping plant, at £1,370. 16s.

Battersea.—The Lighting Committee recommend that the tender of W. T. Glover and Co. be accepted for the supply of the necessary cable to connect No. 8 turbo-generator set with the main switchboard for £88. 15s. 11d.

Stoke Newington.—The Council have accepted the tender of the Reason Manufacturing Co. for the supply of meters; and for the erection of an electrical transformer station the tender of Patman and Fotheringham, at £3,273.

Hammersmith.—The Guardians have accepted the tender of W. J. Fryer and Co., Bravington Works, Paddington, for a complete wiring installation for the electric lighting of their new workhouse and infirmary at Wormwood Scrubbs: electric wiring, £4,580; transforming apparatus, £1,051.

Acton.—The District Council have resolved to purchase an additional transformer from the British Transformer Co. at a cost of £136, and for the low-tension switchgear in connection with the motor-generators purchased from the Metropolitan Co. the tender of Messrs. Cowans, at £276, has been accepted.

Switchgear, etc.—Messrs. Ferranti Limited, Hollinwood, Lancashire report the following contracts: Cardiff, motor-generator switchboard; Burnley, and Newcastle and District Electric Lighting Co., continuous-current switchgear extension; Metropolitan Electric Supply Co., Willesden, 3,000-kw. 11,000-volt switchgear extension; 10 alternate-current and continuous-current switchboards for private installations; Heriot-Watt College, Edinburgh, three 10-kw. alternate-current transformers; Mauritius, two 20-kw. three-phase transformers.

Cardiff.—The Asylum Committee have accepted the tender of D. Firth and Co., Manchester, to do the wiring and general electrical installation work at the new asylum at Whitchurch. It will be remembered that the original tender was for £7,198, but on the suggestion of the committee a cheaper scheme was prepared, and all the firms who had tendered were asked to give fresh prices. Messrs. Firth were the lowest of 16 tenders. The nearest local firm to the successful tenderers were Clay Bros. and Co., of Cardiff, whose original price was £7,850, and whose second quotation was £6,964.

Loughborough.—The following tenders for a year's supply of stores, etc., have been accepted by the Committee: (1) oils, Valvoline Oil Co.; (2) engine-room stores, G. Hatch, Limited; (3) cables and (4) cable accessories, W. T. Henley's Telegraph Works Co.; (5) house service meters, British Thomson-Houston Co.; (6) switches and fuses, Marples, Leach, and Co.; (7) 440-volt motors and starters, Brush Co.; (8) 220-volt motors and starters, Crompton and Co.; (9) ironmongery, sundries, etc., W. Armstrong and Son; (10) house service fuses, W. T. Henley's Telegraph Works Co.; (11) turbine-generator brushes, Brush Co.

London, E.—The Stepney Borough Council have received the following tenders for supply and delivery of meters, etc.: Meters up to a capacity of 10 amperes—Reason Manufacturing Co., £320 (accepted); Chamberlain and Hookham, £320; Ferranti Limited, £326. 5s. Meters above a capacity of 19 amperes—Ferranti Limited, £297. 18s.; Chamberlain and Hookham, £306. 12s. 6d.; Reason Manufacturing Co., £314. Meters above a capacity of 10 amperes—Ferranti Limited (accepted). Combined meter and demand indicator—Reason Manufacturing Co., £770. 4s. 6d. (accepted); General Electric Co., £877. 12s. Demand indicators only—Reason Manufacturing Co., £347. 17s. Carbons—F. Henrion, 79, Mark-lane, E.C. (accepted). Storage tanks—Newton, Chambers, and Co., £687 (accepted).

Fulham.—The following tenders have been received for the supply and construction of extension of cables, feeders, etc.:

W. F. Dennis and Co.	£1,779	7	6
Johnson and Phillips's Electric Cable Works	1,780	4	8
Electrical Co.	1,905	7	6
British Insulated and Helsby Cables (stoneware ducts)	2,000	8	9
Ditto (fibre ducts)	2,064	18	9
Western Electric Co.	2,043	19	6
Ditto	2,115	19	6
W. T. Henley's Telegraph Works Co. (fibre ducts)*	2 075	3	0
Ditto (stoneware casing)	2,012	3	0
Callender's Cable and Construction Co.	2.104	2	6
W. T. Glover and Co.	2,132	8	0
St. Helens Cable Co.	2,209	0	0
Ditto	2,315	15	0
Siemens Bros. and Co. (fibre conduit)	2,362	10	0
Ditto (stoneware conduit)	2,295	0	0

* Recommended for acceptance.

Paris.—None of the tenders for copper wire covered with india-rubber and cotton dipped in paraffin, which were called for July 12, were accepted by the Post and Telegraphs Department. There were five lots, and no reasons are given except that in Lot 1, which probably holds good for the rest—namely, that the prices were above the maximum fixed. We give the results as they appear in the current number of *La Metallurgie*. The figures represent francs per kilometre: A 1 conductor, model 336, No. 1, 20 kilom.—De la Mathe 145, Sté industrielle des téléphones 139, Grammont 130, the India Rubber 129; Cie générale de constructions électriques 125 le kilom. A 2 conductors, model 336, No. 2, 100 kilom.—De la Mathe, 258·90, Sté industrielle des téléphones 259. Grammont 260, the India Rubber 259; Cie générale de constructions électriques 255. Ditto, 200 kilom.—De la Mathe 258, Sté industrielle des téléphones 249, Grammont 252, the India Rubber 256; Cie générale de constructions électriques 262. Ditto—De la Mathe 257·50, Sté industrielle des téléphones 249, Grammont 245, the India Rubber 256, Cie générale de constructions électriques 265·50. A 3 conductors, model 336, No. 3, 100 kilom.—De la Mathe 393, Sté industrielle des téléphones 389, Grammont 380, the India rubber 388, Cie générale de constr. méaniques 399, Alliot et Roi 400.

Metropolitan Asylums Board.—The tenders of the following firms for a year's supply of electrical accessories have been accepted: Pryke and Palmer; General Electric Co., 69-71, Queen Victoria-street, E.C.; Electrical Co., 131-125, Charing Cross-road, W.C.; Goossens, Pope, and Co., 5, Arthur-street, New Oxford-street, W.C.; McGeoch and Co.; Sunbeam Lamp Co., Park-road, Gateshead-on-Tyne; Veritys Limited, 31, King-street, Covent garden; Armourduct Manufacturing Co., 6, Farringdon-avenue, E.C.; Berliner Telephone Manufacturing Co., 200, Upper Thames-street, E.C.; Berry and Skinner, 75, Upper Thames-street, E.C.; British Insulated and Helsby Cables, Helsby, near Warrington; Johnson and Phillips, Electric Light Works, Charlton, Kent; London Electric Wire Co., Playhouse-yard, Golden-lane, E.C.; W. T. Henley's Telegraph Works Co., Blomfield-street, London-wall, E.C.; Edison and Son United Electric Light Co., 36 7, Queen-street, E.C.; Frankenburg and Sons, Greengate, Salford; Sun Electrical Co., 118-120, Charing Cross-road, W.C.; Tucker and Co., Sampson-road North, Birmingham; Baxter and Caunter, 86, Charing Cross-road, W.C.; G. Braulik, 217-218, Upper Thames-street, E.C.; Brush Electrical Co., 106-112, Belvedere-road, S.E.; Connolly Bros., Vale Mills, Blackley, Manchester; Davis, Kent, and Stewart, 17, Berners-street, W.; H. Greene and Co.; Siemens Bros., 12, Queen Anne's gate, Westminster, S.W.

London County Council.—The Highways Committee have received nine tenders for the supply of the high and low tension switchgear

Digitized by Google

required for the four sub-stations at Battersea, Clapham, Streatham, and Wandsworth respectively as follows:

Edison and Swan United Electric Light Co., London...	£8,427	0	0
General Electric Co., Manchester*...	10,129	12	0
Electric Construction Co., Wolverhampton...	10,317	10	0
Siemens Bros. and Co., London...	10,568	10	0
A. Reyrolle and Co., Hebburn-on-Tyne...	11,421	19	0
Dick, Kerr, and Co., London...	12,042	6	3
Kelvin and J. White, Glasgow...	12,335	6	0
British Westinghouse Electric and Manufacturing Co., London...	12,705	7	0
British Thomson-Houston Co., Rugby...	13,178	6	0

* Recommended for acceptance, with power to sublet to the undermentioned firms (or to such other persons or firms as might be approved by the engineer under the contract), as follows: (1) to Ferranti Limited, Hollinwood, the manufacture of the alternating-current ammeters, voltmeters, and wattmeters, (2) to the British Westinghouse Electric and Manufacturing Co., London, the manufacture of the starting resistances and pillars, and (3) to W. T. Henley's Telegraph Works, London, the supply of the cables. The Edison and Swan United Electric Light Co. withdrew because the sub-tenderers found it necessary to increase their prices.

The same committee have received 18 tenders for the supply of the low-tension switchboards required for the Battersea and Wandsworth sub-stations of the London County Council tramways, as follows:

Evered and Co., Birmingham*...	£1,347	10	0
Edison and Swan United Electric Light Co., London...	1,439	16	3
J. Fowler and Co. (Leeds), Leeds...	1,732	0	0
J. G. Statter and Co., Birmingham...	1,732	9	0
General Electric Co., London...	1,855	7	6
L. Robinson and Co., Thames Ditton...	1,982	18	0
J. E. Spagnoletti and Co., London...	2,008	10	0
Electric Construction Co., Wolverhampton...	2,053	10	0
B. Thomas, Manchester...	2,055	18	6
British Westinghouse Electric and Manufacturing Co., London...	2,101	1	0
C. Hodges and Co., London...	2,157	14	0
Consolidated Electrical Co., London...	2,226	0	0
Siemens Bros. and Co., London...	2,344	0	0
A. Reyrolle and Co., Hebburn-on-Tyne...	2,382	9	6
Walsall Electrical Co., Walsall...	2,564	4	6
British Thomson-Houston Co., Rugby...	2,701	14	0
Kelvin and J. White, Glasgow...	2,853	9	6
Baily, Grundy, and Barrett, Cambridge...	3,148	5	6

* Recommended for acceptance, with power to sublet to the undermentioned firms (or to such other persons or firms as may be approved by the engineer under the contract), as follows: (1) to Evershed and Vignoles the manufacture of the ammeters and voltmeters; (2) to Elliott Bros., London, the manufacture of the recording instruments; and (3) to B. Thomas, Manchester, the manufacture of the circuit breakers.

Tenders were also received for electric lighting service in the ranger's house, Blackheath:

Wright, Methuen, and Co.*...	£174	2	0
Ward Bros., London...	175	0	0
Tamplin and Makovski, London...	176	7	6
Hooper, Neary, and Co., London...	187	5	0

BUSINESS NOTES.

LIGHTING AND GENERAL.

Ashton.—The Guardians' new hospitals are to be lit by electricity.

Battersea.—The Council propose to extend the electric lighting to Nine Elms Ward at a cost of £15,000.

Croydon.—The General Post Office contemplate the opening of telephone exchanges at Purley and Kenley.

Sunbury.—The National Telephone Co. have obtained permission to place their wires underground in Thames street.

Islington.—The electricity department of the Borough Council visited Portsmouth for their annual outing last week.

Cardiff.—We understand that a loan of £600,000 is to be raised in which provision is made of £228,587 for electric lighting purposes.

Westminster Electric Supply Co.—The directors have declared an interim dividend for the half-year ended June 30 at the rate of 13 per cent. per annum.

Bedwellty.—A company is being formed for the purpose of making an application to Parliament to supply the urban district of Bedwellty with electrical power.

British Promotheus Co.—The works of this company will be closed from Aug. 2 to 12 next (inclusive) for the purposes of an annual holiday and stocktaking.

Metropolitan Electric Supply Co.—The directors have declared an interim dividend of 5s. per share on the £5 ordinary shares, being at the rate of 10 per cent. per annum.

Huddersfield.—During this month 15 new consumers and 874 lamps have been connected.

Malton.—The Urban District Council have decided to give the electric light a trial for street-lighting.

Johnstone Extension.—Strong efforts are being made by Howwood and Lochwinnoch residents to induce the Paisley District Tramway Co. to extend their system to these districts.

County of London Electric Supply Co.—The directors have declared an interim dividend on the ordinary shares at the rate of 4 per cent. per annum, less tax, payable on Aug. 21.

Durham.—The County Council will be asked at the next meeting to consider the promotion of a Bill in Parliament with the object of establishing a system of electrical service in the county.

Chertsey.—The engineers of the Chobham and Windlesham electric lighting scheme have decided not to place overhead wires along the public roads, and have completed their plans for laying mains.

Selby.—The Electrical Distribution of Yorkshire Co. intend to apply for a provisional order, under the Electric Lighting Act, authorising them to supply electric power within the urban district.

Hayward's Heath.—The Rural District Council have invited the promoters of the Hayward's Heath Electric Supply Co. to attend a special meeting of the Council and discuss the question of a supply.

Watford.—The electrical engineer's last report shows that the number of consumers connected to date is 410. It is proposed to construct and equip two sub-stations similar to those at present in use.

Case-Hardening.—We have received from Messrs. W. H. Palfreyman and Co., 17, Goree-piazzas, Liverpool, an interesting little pamphlet describing how the best results in case-hardening may be obtained.

Waterloo and City Railway Co.—The directors recommend a dividend at the rate of 3 per cent. per annum for the half-year ended June 30, carrying forward £658. The dividend at June, 1904, was at the same rate.

Llanelly.—A public meeting of ratepayers was held at the Llanelly Market Hall last week to discuss the Council's proposal to adopt a scheme of electric lighting. After discussion the meeting adjourned for a fortnight.

Diamond Cutting.—Mr. Leopold A. Claremont, managing director of Claremont Limited, in a letter to the *Daily Telegraph* says that it was a London firm who first applied electromotive power to the purpose of diamond polishing.

Rawtenstall.—The Board of Trade have approved the system to be adopted by the Town Council for the supply of electrical energy. Plans and estimate are before the Local Government Board, with an application to borrow £12,000.

Portland.—The National Provincial Electricity Corporation intend to apply for a provisional order to empower them to supply electricity for all purposes within the urban district. Steps are also to be taken for the purpose of applying for a provisional order on behalf of the Council.

Ossett.—A ratepayers' meeting was held on Monday to consider the advisability of erecting an electricity station, and a resolution was passed to the effect that if the Board of Trade refused to extend the time of the provisional order, a scheme not to exceed £4,000 might be promoted.

Retford.—The Town Council have been served with a notice by a London firm of intention to apply for parliamentary powers to supply electricity in the borough. In 1899 the Town Council received a provisional order to supply electricity within the borough, which has since been cancelled.

Torquay.—It has been arranged to accept the offer of the Dolter Co. for their engineers to consult with the borough electrical engineer as to the feasibility of carrying out the scheme of extension of the present station, the approximate cost of which it is roughly estimated would not exceed £6,000.

London Electric Supply Corporation.—The units sold for the half-year ended June 30 last amounted to 6,130,461, of which 4 039 970 units were for power purposes, producing a total revenue of £62,886, as compared with 4,494,220 units sold in the corresponding period of 1904, producing £64,776.

Queen's Hall Orchestra.—This year's promenade concerts at Queen's Hall will be held from Aug. 19 to Oct. 27. We have seen an attractive list of orchestral compositions which are to be performed for the first time in London by the Queen's Hall Orchestra, under the conductorship of Mr. Henry J. Wood.

Norton.—An agreement has been arrived at between the Urban District Council and the Northern Counties Electricity Supply Company whereby the Council agree to waive their right to the provision of a generating station in Norton, and the company undertake to at once commence to lay down a cable from Malton.

Leith.—Last week Judge Craig laid the last brick of the chimney stalk at the extension of the electric lighting station. Messrs. John Dennis and Co., Dalkeith, were the contractors. There are over 101,000 lamps connected with the station, which is now able to supply all the energy required for the working of the electric tramways.

Bridlington.—The Town Council propose to apply for sanction to borrow £4,500 (in addition to £1,500 for which application has already been made) for necessary extensions in connection with the electric lighting scheme, as the demand for current has been greatly in excess of anticipations, though ample provision has been made for extensions.

Anglo-American Telegraph Co.—The directors have resolved, after placing the sum of £5,000 to credit of the renewal fund, to declare an interim dividend for the quarter ended June 30, 1905, of 14s. per cent. on the ordinary stock and £1. 8s. per cent. on the

Digitized by Google

preferred stock, leaving a balance of about £1,250 to be carried forward.

West Ham.—The accounts of the Corporation tramways for the year ending March 31 last show a gross profit for the year of £23,198. Of this sum £9,020 is absorbed by interest on the undertaking, and the net profit is £14,418. Of this sum the Corporation has placed £7,418 to the sinking and renewal fund, and have carried £7,000 to the relief of the rates.

Sale of Plant.—The Aston Manor Corporation invite tenders for the purchase and removal of the following apparatus: 280 (approx.) Electrical Company's tariff clocks, mechanically wound, 30 days; 100 Aron time switches (Wilson system), electrically wound, with warning coil; and 25 Schuckert time switches, electrically wound. For particulars see advertisement column.

Wrexham.—The Corporation have again demonstrated that the combination of refuse destructor with electricity works can, under able management, be worked successfully. We are informed that Mr. Sillery, the electrical engineer, has reported that the Meldrum destructor had worked continuously for 12 months without stoppages and without incurring a cost of one penny for repairs.

Fulham.—Messrs. Allen and Norris are about to build some 400 flats in the vicinity of Woodlawn-road, and have arranged to have them wired for electric lighting. The Council having decided to adopt prepayment meters, and to make a charge of 4d. per unit for current consumed, 25 meters for penny-in-the-slot are to be obtained from the British Thomson-Houston Co. at a cost of £103. 2s. 6d.

Faversham.—The electrical engineer reported at the last Council meeting that, on the basis of the expenditure of last year, the cost of the street electric lighting for the ensuing year would be £22 for each of the 10 arc lamps and £4 for each of the other lamps. A notice was tabled to the effect that, owing to the cost of the arc lamps, the question of substituting for them some other kind of electric lamp be considered.

Stock Exchange.—Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to the Yorkshire (West Riding) Electric Tramways Co.'s £275,000 4½ per cent. first debenture stock, and to allow the Edmundson's Electricity Corporation's further issue of 10,000 ordinary shares of £5 each, fully paid, Nos. 70,001 to 80,000, to be quoted in the official list.

Grimsby.—Mr. W. A. Vignoles, the borough electrical engineer, in his last report states that as the result of the year's working the committee had made £895 profit, which could be voted to the relief of the rates. The undertaking is only four years old, yet the engineer estimates next year's profit at £1,500, while if a proposed agreement with a probable large consumer is completed, the undertaking would in about three years be able to repay the whole of the money received from the rates.

Loughborough.—The Town Council have decided on the recommendation of the electrical engineer, Mr. W. H. Allen, to reduce the price of current to the following: private house and shop lighting, 4d. per unit; factory and workshop lighting in bulk, 3d. per unit; current for motors, radiators, fans, and all heating and cooking apparatus, except between 5 and 11 p.m., 1d.; current for ditto between 5 and 11 p.m., 3d. per unit. These reductions will come into operation as from July 1, 1905.

Woolwich.—Application is to be made to the London County Council for an advance of £5 610 for a further scheme of street-lighting by electricity. An electric lighting scheme has been adopted, subject to an estimate being passed by the Finance Committee, and the sanction of the London County Council being obtained to the borrowing of the amount required—for Woolwich parish, £4,387. 11s 10d.; Eltham parish, £415. 16s. 6d.; estimated cost of side street lighting, £805. 14s. 6d.—a total of £5,609. 2s. 10d.

Lighting Big Ben.—In the House of Commons last week Mr. Lough asked Lord Balcarres what was the cost of lighting "Big Ben," and what was the estimated saving by colouring one or more of the dials green, as opposed to red. Lord Balcarres said the cost of lighting the dials of the clock electrically amounts to £242 for the year. The green light is incidental to the lamp used experimentally, and the cost of current, if it was adopted permanently, would be reduced some 35 per cent. A red colour, being impracticable, has never been used.

London Gazette.—A first and final dividend of 1s. 10½d. in the £ has been declared in the estate of James William Hunter, electrical engineer and motorcar dealer, 8, Norwood-road, Leeds, and trading with Albert Chapman as the Yorkshire Motorcar and Electrical Engineering Co. The partnership between Austin Isherwood and George Richardson Burnett, carrying on business as electricians, electrical engineers, and contractors, at 37, Surrey-street, Sheffield, under the style of the Sheffield Electric Bell and Telephone Co. has been dissolved by mutual consent.

Private Bills.—The following Bills have been read a third time in the House of Lords and passed: Metropolitan and Great Central Railway Companies, Gosport and Fareham Tramways, Hastings Tramways, South Lancashire Tramways, North Metropolitan Electric Power Supply, Metropolitan Electric Tramways, Dublin United Tramways, Charing Cross, Euston, and Hampstead Railway, Baker-street and Waterloo Railway, Edgware and Hampstead Railway, South Barracas (Buenos Ayres) Gas and Coke Company, Great Northern Railway (Ireland), Great Northern, Piccadilly, and Brompton Railway (No. 1), and the Shropshire, Worcestershire, and Staffordshire Electric Power Bills.

Burnley.—An inquiry has been held into the application of the Town Council for sanction to the borrowing of £16,194 for the purposes of electricity undertakings. Major Norton, the assistant town clerk, stated that the total amount sanctioned for the purposes of the undertaking was £85,844, the actual amount raised was £78,524, and the outstanding debt was £64,319. During the last three years the profits of the electricity undertaking, after paying interest and sinking fund charges, for the year ending March 31 last amounted to £8,307; for 1904, £5,123; and for the year 1903 to £3,552. The acting electrical engineer, Mr. Starkie, gave figures showing how the electricity works had developed, mentioning the electrification of the tramways. He considered that with the new extensions and additions the town would be fairly well equipped for some time to come.

London County Council.—At Tuesday's meeting of the Council tenders for the manufacture, supply, and delivery of one five-ton and one 2½-ton overhead electrically-driven travelling crane were referred to committee for consideration and report. It was agreed to lend the Poplar Borough Council £10,818 for electric light purposes. The Highways Committee recommended that expenditure on capital account, not exceeding £30,000, be sanctioned in respect of the construction of the foundations and the erection of the chimneys for the second portion of the Greenwich electricity generating station; and that the drawings, specifications, and estimate of £28,000 for the construction of the foundations and the erection of the chimneys for the second portion of the Greenwich electricity generating station be referred to the Works Committee with a view to the execution of the work without the intervention of a contractor.

Hampstead. — The Lighting Committee recommended last Thursday week that, with the commencement of the New Year, the charges for electric current to private consumers for lighting be 6d. per unit for the first hour's average maximum demand per day, and 1½d. per unit for all current consumed beyond that quantity during each quarter for the winter quarters, and a uniform charge of 1½d. per unit for the summer quarters, instead of 6d. per unit for the first hour and 2½d. for the remainder during the whole year as previously. They further recommended that the question of making any alteration in the meter rents stand over for the present, and that no alteration be made in the present charges for heating and power. An amendment, that the whole matter be referred back to the committee, with instructions to bring up the full reports of the officials and the whole of the information placed before the committee, was carried.

Wigan.—The Wigan Corporation Bill has passed the House of Commons after amendment in committee. Under it the Corporation sought, amongst other powers, to acquire provisional orders for electric lighting in the districts forming the Wigan Poor-Law Union. This district is already included in that of the Lancashire Electric Power Co., who accordingly offered strong opposition to the above proposal. After hearing evidence on both sides the Select Committee of the House of Commons allowed the Wigan Corporation to take over the electric lighting order of Ince, but refused the power sought to supply electricity elsewhere with the poor-law union. The evidence in opposition to the Bill showed that a good deal of power was likely to be required by the collieries within the area. The committee was evidently convinced that this class of work should be done by the Lancashire Electric Power Co. rather than by a municipal body.

Charing Cross Electric Athletic Association.—The members of the above association held their first annual sports on their ground at Acton on Saturday, July 22, 1905, before a large gathering of friends. The cup presented by the president (W. F. Fladgate, Esq.) for the highest number of points scored was won by Mr. W. B. Schroder, Mr. H. Davies being second. After the sports Mrs. J. Gatti presented the prizes, and a most enjoyable day ended with a dance on the lawn, in which a great many took part. Amongst the results we note: 100 yards—(1) H. Davies, (2) W. B. Schroder, (3) H. Miller; veterans' race—(1) J. Usher, (2) J. Eness, (3) H. J. Payne; 440 yards' handicap—(1) F. Wallington, (2) A. Nicholls, (3) T. Jones; long jump—(1) C. R. Oldfield, (2) W. B. Schroder; one-mile championship—(1) H. J. Henbrey, (2) W. Webb, (3) A. Patter; two-mile walk—(1) T. O'Gorman, (2) G. Connor, (3) F. Palmer, (4) E. Suffling; high jump—(1) H. Davies, (2) F. A. Smith.

Birmingham.—Mr. Ellaway, in moving the adoption of the report of the Electric Supply Committee, pointed out that while the probable requirements of energy for tramway purposes during 10 years was estimated at 7 500 kw., provision was only asked for the installation of 3 600 kw., leaving a margin of 4,000 kw. to be added as occasion arose. The additions proposed were necessitated by the scheme of the Tramway Committee for the extension of the tramways, involving the laying of about 31 miles of entirely new lines. The additional equipment at Summer-lane provided for the installation of 1,500 kw. of direct-current supply, and 1,500 kw. of alternating-current supply. With regard to the three sub-stations already sanctioned, the intention was to build them only at present to about half their ultimate size, but the committee were now satisfied that it was the wiser and more economical plan to now erect them to their full size. To the £10,500 for the building of the three stations they now added a further £16,000. The cost of the high-tension lighting cable connecting Summer-lane to Saltley was £6,000, and they asked for £10,000 for lighting mains and feeders for opening up the district. They would, of course, only spend the latter sum as they got applications for a supply. The total sum required for the extensions was close upon £100 000. The report was approved without discussion.

Newcastle.—Mr. Ernest Hatton in a recent report says the net receipts over the expenditure for the present 200 arc lamps, at an annual cost to the Lighting Committee of £2,980, amounted to £317, which sum allowed for ample depreciation on the equipment. The report shows that during the year ended March 31, 1905, 8,581,301 units were produced and distributed as follows: units used in power station, 273 325; at pumping station, 380,575; leaving a net balance for disposal of 7,927,401 units. The total cost of production was £33,541, including all capital charges, rents, rates, etc., or 1·015d. per unit; 328,393 units were now used for the present 200 arc lamps. It is proposed to increase the number for a further 160 arc lamps,

Digitized by Google

making a total of 360 arc lamps. This will necessitate a further expenditure on cables, etc., and new lamps of £4,500. The total cost of this additional supply, providing 8,194,008 units, will be £33,753, or a total cost of ·989d. per unit. As it is proposed to reduce the price paid per lamp from £15. 10s. to £12 per annum, the total revenue derived from the 360 arc lamps will be £4,320, and the expenditure, including additional maintenance on the increased number of lamps, together with the additional capital charges, will be £4,239 per annum, leaving a net balance of £91, in lieu of £317 now derived from the present installation of 200 lamps, at a total expenditure to the Lighting Committee of £2,960.

Govan.—In his report on the working of the Govan electricity department for the year ending May 15, 1905, Mr. Theodore Parsons states that nearly all the contemplated extensions are now completed. The new engine-room has been completed, and the overhead crane, 750-kw. steam dynamo and condensing plant and piping erected, and the 600-kw. steam dynamo shifted from the old to the new engine-room. Eighty-five long-hour arc lamps, with raising and lowering gear, have been erected, and various extensions to the mains have been made. The balance of profit is £411, which, with the balance carried over from last year, amounts to £727, which has been placed to the renewals fund account. The result is very satisfactory, as bad debts of £108 and buildings taken down, £407, were written off, and about £600 of income was lost due to the failure of one of the consumers, and £365 due to the new street lamps being late in erection. All the working costs show decreases except the oil, waste, etc., which have risen ·003d. per unit sold. The coal cost has gone down ·052d. per unit. The maximum load in kilowatts is only 100 higher than last year, which is due to the loss of a large consumer and to the fact that the new street lamps were not connected until after January, 1905. The cost of attending to street lamps has been reduced to ·555d. per unit, and should be still lower in the coming year. The applications for both light and power were higher than in any previous year.

Erith.—The annual report of the electrical engineer (Mr. G. E Heath) on the working of the electricity supply undertaking for the year ending March 31 last contains the following statistics: The connections made to the mains during the year were 3,771 8 c.p. lamps, 5,275 h.p. in motors, and the equivalent of 203 8 c.p. lamps in public lighting, the totals now being 17,359 8-c.p. lamps and 231·75 h.p. in motors. The street-lighting comprises 17 arc lamps, 34 32-c.p lamps, 458 two 8-c.p., and 84 half-ampere Nernst lamps. The total mileage of the cable laid during the year is 2 63 miles, made up as follows: ·44 miles of high-tension feeder, ·90 miles of low-tension distributor cable, and 1·29 miles of street-lighting cable, bringing up the total mileage of cable laid to 59 2 miles. Substantial reductions have been effected in each item with the exception of coal, resulting (notwithstanding an increased coal cost) in a net reduction of ·267d. per unit generated on the total costs, and ·323d. per unit sold. The standing charges have risen from £1,878 to £2 824. In view of the conditions above mentioned, a gross profit of £1,959 with a reduction in the generation costs of ·267d. per unit conclude a satisfactory year. The general statement accompanying the report shows the total capital expended to have been £51.648. 11s. 0½d.; gross revenue, £7,176. 3s. 9d.; gross expenditure, £5,151. 15s. 1½d.—gross profit, £2 024. 8s. 7½d. Average price obtained per unit: private lighting, 4 938d.; power, 1·586d.; street lighting, 1·669d. Interest and sinking fund, £2 821. 2s. 7d.; balance on year's working—deficit, £799. 13s. 11½d.—gross profit, £2,024. 8s. 7½d.

TRACTION.

Limerick.—An inquiry has been held into the proposed Limerick tramways scheme.

Dover.—The extension of the municipal electric tramways through the country district to River is expected to be opened for traffic in August.

Derby.—The extension of the electric tramway from the Market Head to the borough boundary on the Kedleston-road has been practically completed.

Colchester.—The Colchester electric tramways on July 28, 1904, complete their first year. Up to Thursday last week the total receipts had come to a little over £11,000.

Aberdeen.—All the tramway standards on the various routes of the city have been numbered so that the repairer can find the required posts easier, as most repairs are done at night.

Heywood.—The Tramways Committee have arranged that their proposed electric tramways, the construction of which is about to be commenced, will be worked at 4½d. per car mile.

Tramwaymen's Sports.—The annual sports in connection with the Southport Corporation Tramway Employés' Social and Athletic Society took place on Wednesday and Thursday of last week.

Auckland.—The Rural District Council will not oppose the application of the United Kingdom Tramway Syndicate for the prolongation of the time fixed for the commencement of the tramway scheme.

Wednesbury.—The work of reconstructing the tramways between Wednesbury and Darlaston is proceeding satisfactorily. It is expected that the cars will be running by the latter end of August or the beginning of September.

Ashton.—The Ashton Tramway Committee and the Stalybridge Joint Electricity Board have at last settled their difficulties, it is said, satisfactorily to both parties. On Monday through running commenced, the fares remaining as hitherto.

Brighton.—The Corporation have inaugurated a system of personally conducted touring cars, which twice daily leave the Aquarium terminus for a circular trip to the points of interest about Brighton. The journey covers about nine miles, and occupies nearly two hours.

Lewisham.—The Council have authorised the Special Tramways Committee to join with the committee of tradesmen in Sydenham and Forest Hill in a deputation to the London County Council to urge upon them the necessity for the early extension of the tramways in that district.

Watford.—The Herts County Council have sealed amended agreements with the Urban District Council of Watford and the Metropolitan Electric Tramways Co. with regard to the Watford light railways. We understand the Watford Urban District Council will supply the current.

The Edinburgh and Queensferry Tramways.—At the conclusion of the inquiry under the Private Legislation Procedure (Scotland) Act, 1889, into the draft provisional order on the Edinburgh and Queensferry tramways, the Commissioners intimated that they held the preamble not proved.

Cricklewood to Marble Arch.—Mr. B. B. Evans is making efforts to bring about a Marble Arch-to-Cricklewood tramway scheme. He will ask the Willesden and Hampstead Councils to have a conference to consider the questions of trams and widenings, and to test the feelings of neighbouring public bodies.

Wolverhampton and Cannock Chase Railway Co.—An inquiry has been held into the application of the Wolverhampton and Cannock Chase Railway Company for a light railway order. The chairman said the order would be recommended for granting, subject to the readjustment of clauses for the line to be run as a light railway.

Nelson.—The Burnley Corporation and the Colne and Trawden Light Railways Co. have agreed to cheap fares over their respective systems for parties of not less than 10, to be carried on ordinary service cars. The Nelson Council have approved of the arrangement, subject to the inclusion of cheap fares for similar parties between Nelson Centre and Townley, Manchester-road Summit, Rose-grove, and Padiham.

Liverpool Overhead Railway Co.—The accounts for the past half-year show an available balance of £7,883. 6s. 8d. The directors have resolved to recommend payment of a dividend at the rate of 5 per cent. per annum on the preference shares and carry forward a balance of £4,335. 11s. 6d. Last year at the corresponding period a dividend of 1½ per cent. per annum was paid on the ordinary shares and £4,052. 5s. 10d. balance carried forward.

Shildon.—The United Kingdom Tramways and Light Railways Syndicate propose to apply to the Board of Trade for a prolongation of the time limit in respect of the commencement and completion of the work of laying the proposed tramways. We understand that the Urban District Council have passed a motion to the effect that the proposed extension of time be objected to unless the syndicate were willing to pay the Council a wayleave of £50 per mile per annum.

Birmingham.—The Tramway Bill promoted by the Corporation relates to the building of depôts, the construction of new lines, etc., which will cost about £1,000,000. It is expected that all the existing lines, with the exception of the cable route, will be electrically equipped by the time the leases expire in 1906. The time-limit for the construction of the new lines is five years, as large street widenings are necessary. The electrical equipment is estimated to cost £600,000.

Falkirk.—Good progress is being made with the construction of the tramways, both in the burgh and in the county. A consignment of cars has arrived at Grangemouth per s.s. "Donavon" from Dunkirk. The cars are in parts, and on arrival in Falkirk will be put together and the motors connected with them fitted in. They are large, roomy, and comfortable looking, and artistic in design and finish. They have been supplied by Messrs. Bruce Peebles and Co., Edinburgh, the principal contractors for the tramway.

District Railway.—Electric trains commenced to run on the Putney Bridge to High-street, Kensington, section of the District Railway on Sunday last. For the present there will be no through electric service from Putney to the City, but passengers on the Putney line may, by changing at Earl's Court, complete the journey in one of the electric trains running between Ealing and Whitechapel. The Richmond section will be the next electrified section to be opened. The electric trains to Wimbledon will be started in a week or two.

Huddersfield.—The Council have adopted a report, in which the Tramways Committee recommended that the manager be given sole control over the employés of the tramway department, with power to dismiss or suspend, and that the manager be instructed to post up a notice that henceforth any motorman found abusing his equipment in definance of the regulations will be summarily dismissed. All ticket inspectors are in future to be fully qualified motormen, and their duties will include the supervision of the motormen as well as the conductors.

Poole.—The Railways Committee have reported the receipt of a letter from Mr. J. J. Norton calling the attention of the Council to the obligation resting upon them of constructing a light railway through Parkstone under the Poole and District Light Railway Extension Order, 1902. The town clerk will apply to the Board of Trade to extend the time for executing the works for a further period of two years; and after having obtained the concurrence of the Branksome Urban District Council, will ask the Bournemouth Corporation whether they are willing to undertake the construction of the line, subject to plans, etc., and method of construction being approved by this Council and the Branksome Urban District Council. Similar steps will be taken with regard to the proposed extension to the Sandbanks district.

Tramway Construction Contracts.—We understand that Messrs. J. G. White and Co., who are now making an issue of capital, have just secured a contract, amounting to upwards of £400,000, for the complete construction of tramways, etc., at Para, Brazil. If the report of the Traffic Commission is acted upon, it will, no doubt, give an impetus to tramway construction in London. Messrs. White were the

Digitized by Google

pioneers of the conduit system of electric traction in London, and they have carried out works amounting to over £400,000 for the London County Council during the last few years. They are at present carrying out a large contract for the London United Tramways, and will also be entrusted with the conversion to electric traction of the Bombay (India) tramways system. With the large amount of contract work already in hand, amounting to over two million pounds, and the bright outlook for the future, the continued success of the company appears very promising.

Portsmouth.—The balance sheet of the Corporation tramways for the year ending March 31 shows the undertaking to be increasingly prosperous. The total receipts amounted to £100,973, of which £91,705 was from fares, £1,093 from advertising on the cars, and £5,564 for the sale of current to the light railway company. The total expenditure for maintenance and repairs was £44,165, so that there was a gross profit of £56,807, equivalent to rather more than 8 per cent. on the capital outstanding. From this total £18,696 has to be deducted for interest charges, £15,930 for the sinking fund, and £934 for income tax. This brings the net profit down to £21,246, to which has to be added the sum of £712 dividends on investments, so that the available surplus is £21,959. The committee have spent £5,608 upon the Somers-road and Circle improvements, and £2,107 for workshop and other improvements, and for balancing various outstanding capital charges for which money was not borrowed. These two payments reduce the balance to £14 243, and the committee propose to add this to the reserve fund, which will then amount to £37,236.

Light Railways in the Potteries.—The Light Railway Commissioners have held an inquiry into an application of the North Staffordshire Railway Co. for an order authorising them to work certain mineral branches of their system as light railways. The lines in question were—(1) branch from Apedale Junction to Apedale Ironworks; (2) from Knutton Junction to Pool Dam Canal Wharf, Newcastle; (3) from Normacot to Adderley Green; (4) from Botteslow Junction to Adderley Green; (5) from Longport Junction to Tunstall Junction; (6) from Tunstall to Newfield; (7) from Chatterley Junction to Talk-o'-th'-Hill; (8) from Chatterley Junction to Chesterton; (9) the Grange branch at Burslem; (10) from Stretton Junction to Hawkins-lane Junction, Hornicglow; (11) from Congleton Lower Junction to Congleton Brunswick; and (12) from Wheelock Station to Sandback. The Potteries Electric Traction Co. opposed the application as regarded Nos. 1, 2, 3, 5, 6, and 9. Mr. B. C. Brough appeared for the railway company, and Mr. Tildesley Jones for the electric traction company. The Commissioners announced that they were prepared to submit an order to the Board of Trade sanctioning the working of all the lines as light railways except Nos. 2, 5, and 6.

Tramway Damages.—At the Manchester Assizes on the 25th two verdicts were given against the Salford Corporation. One man obtained £90 damages. From the evidence it appeared that when riding on the outside of a Salford tramcar, he was struck by a loose trolley pole. In another case the plaintiff obtained £225 compensation for his personal injuries caused by a collision which was due to one of those obstinate carters of whose objectionable tactics every user of a tramcar is well aware. In giving his evidence, a car driver said that two coal-carts appeared in front of him and monoplised the road, preventing his car from proceeding. The wheels of both carts were over the metals. The witness repeatedly sounded his gong, but although the carters might readily have drawn off to the left, the obstruction continued. The driver of the second cart at length drew away, but the one in advance of him not only maintained his position, but turned and jeered at the witness, putting his thumb to his nose—"as youngsters would"—and laughing at him from under his horse's head. The man persisted in this behaviour, although called to and warned by his companion, and when he did lead his horse out of the way it was to the right instead of to the left. This brought him into collision with the car on the down line. The near shafts of the coal-cart struck the front part of the car (after Tobin had applied his electric brake), pinned Tobin's left arm against the steps, and broke the arm below the elbow.

London County Council.—On Tuesday £50,000 was voted in respect of the acquisition of lands and easements in connection with the construction of the tramway subway from Southampton-row to the Victoria-embankment. Next week the Highways Committee will recommend: (*a*) That the estimate of expenditure on capital account of £59,394, made up of the undermentioned amounts submitted by the Finance Committee, be approved in respect of the equipment of the tramways from the Strand, *via* the tramway subway, to Theobald's-road, and the reconstruction and equipment of the tramways in Theobald's road between the present tramway terminus and the authorised tramways in Rosebery-avenue near Gray's-inn-road—namely: rolling-stock, £33,000; trackwork, £19,870; cables, switchboards, etc., £5,024; lighting, etc., £1,500. (*b*) That the Highways Committee be authorised to make any necessary arrangements with the North Metropolitan Tramways Co. for the electric working as a through route of the tramways in the tramway subway between the Strand and Southampton-row, and of the tramways between Theobald's-road and the Angel, Islington; that an agreement be entered into to give effect to the arrangements; and that the seal of the Council be affixed to such agreement. An expenditure of £4,500 is proposed for the construction of a junction line at St. George's-circus between the tramways in Borough-road and Blackfriars-road. The report of the Highways Committee on the accounts of the receipts and expenditure for the year ended March 31, 1905, in connection with the Council's tramways undertakings south of the Thames is as follows: The London County Council tramways comprise the undertakings transferred to the Council by (*a*) the London, (*b*) the South London, (*c*) the South-Eastern Metropolitan, (*d*) the London, Deptford, and Greenwich, and (*e*) the London, Camberwell, and Dulwich Tramways Companies. The net capital expenditure in respect of the whole of these tramways amounted on March 31, 1905, to £2,623,692. 19s. 2d., of which £208,363. 11s. 7d. has been repaid out of revenue, the amount of the outstanding debt on that date being £2,415,329. 7s. 7d. During the year 1904-5 the net expenditure on capital account amounted to £499,454. 3s. 5d. This amount includes £102 884. 15s. for the purchase of the undertakings of the London, Deptford, and Greenwich Tramways Company and the London, Camberwell, and Dulwich Tramways Company, the remainder being in connection with the reconstruction for electrical traction of certain sections of the tramways. The net capital expenditure up to March 31, 1905, in respect of the reconstruction of tramways for electrical traction was £1,470,018. 13s. 2d. The total receipts from the undertaking during the year, and the working expenses, were as follows: Total receipts—electric traction £548,296. 7s. 1d., horse traction £133 799. 2s., total £682,095. 9s. 1d.; working expenses—electric traction £365,497. 12s. 6d., horse traction £134,323. 1s. 6d., total £499 825 14s; making the gross surplus on working—electric traction £182 798. 14s. 7d., horse traction £523. 19s. 6d. (deficiency)—total £182 259. 15s. 1d. Debt charges, amounting to £136,953. 17s. 9d. (including £576. 2s. 3d. in respect of the widening of Harleyford-street), and a charge of £3 261. 7s. 6d. for income tax, have been set against the sum of £182,269. 15s. 1d. above referred to, and a sum of £35,000 has been transferred to the renewals reserve fund, leaving a net surplus of £7,054. 9s. 10d. to be carried to the appropriation account. This compares with a net deficiency of £8,283. 14s. 2d. in 1903-4, when no amount was set aside for renewals. The total receipts have been £145,856 more than in 1903-4, notwithstanding the fact that Streatham cable tramways were closed during their reconstruction for electrical traction. The exceptionally fine weather during the summer no doubt accounted to a considerable extent for the increased earnings. The total amount of the renewals reserve fund established in connection with the undertakings was, at the beginning of the year 1904-5, £30 772. 4s. 9d. Dividends on investments and interest on the bank balance of the fund amounted during the year to £834. 17s. 9d. The uninvested moneys of the fund were temporarily used to defray the expenditure incurred in the provision of the four temporary generating stations at Loughborough Junction, Deptford, Streatham, and Bankside. The expenditure incurred under this head is £35,203 12s. 3d., of which sum £2,895. 12s. 5d. was charged against the revenue of the year 1903-4, while the remaining £22,307. 19s. 10d., instead of being charged over the whole period during which certain of the temporary stations are to be used, as was originally proposed, has been borne by the revenue of the year 1904-5. The balance of the fund carried forward to the current year is £56,607. 2s. 6d., an increase in the year of £35 834. 17s. 9d. No comparison of working expenses can be made with those of former years owing to the different circumstances obtaining. It may be stated, however, that the total operating expenses for electrical traction were £340,987. 11. 9d., or 7·49d. per car mile run, while the addition of the expenditure in connection with the provision of temporary generating stations mentioned above and other special items increases the revenue expenditure to 8·03d. per car mile run. The total expenses in connection with horse traction work out to 10·23d. per car mile run. We would, however, point out that the working expenses for electric traction have been considerably higher than they are exected to be when the permanent generating station at Greenwich is completed, and when the use of temporary car-sheds can be dispensed with. On the whole, therefore, we regard the result of the year's working, which is considerably more favourable than was anticipated in the annual estimates, as being very satisfactory. The following further facts may be of interest to the Council. The tramways system extends over a total length of about 46⅞ street miles, inclusive of the lines of the London, Deptford, and Greenwich Tramways Co., acquired in July, 1904, but exclusive of the derelict lines purchased from the London, Camberwell, and Dulwich Tramways Co. Of this total length about 26⅝ miles of double track have been reconstructed on the underground conduit system of electrical traction. Electric services on the lines were first started on May 15, 1903, and during the year 1904-5 several further sections of lines were opened for traffic, including the Brixton and Streatham lines and several new routes. The total number of passengers carried and the car miles run during the year were 164,818,560 and 14,081,397 respectively, or 31,679,475 and 2,544,863 more than in 1903-4. The sub-division of these figures between electric and horse traction is as follows: Number of passengers—electric traction, 126,255,230; horse traction, 38,563,280—total, 164,818,560. Number of car miles run—electric traction, 10,931,396; horse traction, 3,150,001—total, 14,081,397. Of the total number of passengers, 35·97 per cent. were carried at ½d. fares, 47·10 per cent. at 1d., 9·12 per cent. at 1½d., 5·01 per cent. at 2d., 1·18 per cent. at 2½d., and 1·62 per cent. at 3d. The average fare per passenger was ·97d., as against ·93d. in 1903-4. During the year an innovation has been made by the use of roof-covers for some of the electric cars, 81 of which were equipped up to the end of the year 1904-5, while others are being fitted. These roof-covers have been much appreciated by the public, and the earnings of the cars have been considerably increased. The tramways stud at the beginning of the year numbered 1,872, and 295 horses were added upon the transfer of the London, Deptford, and Greenwich Tramways Co.'s lines. Owing principally to the institution of electrical traction on some of the lines, however, the stud has been reduced by 847 horses, which have been sold by auction at an average price of £21. 12s. 4d. each. The low average price realised is due to the fact that nearly 400 of the horses sold, which had been recently transferred to the Council from one or other of the companies, were of an inferior standard, and had to be replaced from the Council's own stud by a much better class of horses, which would otherwise have been disposed of. In addition to the horses sold, 20 horses have died and eight cart horses have been bought, so that the stud on March 31, 1905, numbered 1,300 car horses and eight cart horses. The average cost per week for provender and litter has been 7s. 6·28d. per horse, as against 8s. 3·09d. in 1903-4. The permanent way has been well maintained, and the machinery, plant, and rolling-

Digitized by Google

stock have been kept in thorough order and repair. In consequence of complaints as to the noise caused by the running of the tramcars on the Tooting section of the Council's electric tramways, it has been found that the rail joints have in many cases worked loose, and a trial is to be made of the Thermit system of welding rail joints. It has been arranged that 200 rail joints be welded on this principle at a total cost of about £240.

PROVISIONAL PATENTS, 1905.

JULY 17.

14660. Improvements in or relating to vapour electric lamps. Francis Harrison, 157, Grange Park-road, Leyton, Essex.

14663. Improvements for central battery telephone transmitters. Joseph Henry Scales, 94, Stockwell Park-road, Brixton, London.

JULY 18.

11970a. Improvements in electric couplings. The British Thomson-Houston Company, Limited, and Edmund Basil Wedmore, 83, Cannon-street, London. (Date applied for under Patents Rule 9, June 7, 1905.)

14713. Improvements in electric arc lamps. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

14714. Improvements in and relating to electric measuring instruments. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

14715. Improvements in vapour electric rectifiers. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

14736. New electric switch for recording, indicating, and controlling main switches by magnetic coils. Charles Isaac Adams and Walter Brand, 8, Crescent-gardens, Bath, England.

14749. Improvements in electric stop motions for looms. Pierre Vindrier, 6, Bank-street, Manchester.

14751. Improvements in electric dynamos and motors. Cenek Macku, 6, Bank-street, Manchesters.

14770. Improvements in and relating to telegraphic instruments and the like. Alberto Gentili, 27, Chancery-lane, London. (Date applied for under Patents Act, 1901, July 19, 1904, being date of application in Italy.) (Complete specification.)

14780. Improvements in or relating to apparatus for electric welding. Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (The Clinton Wire Cloth Company, United States.) (Complete specification.)

14785. Improvements in connection with frogs and switches and crossings for the overhead conductors of electric tramways and railways. Isaac Everson Winslow, 47, Lincoln's-inn-fields, London.

14788. Improvements in or relating to wireless telegraphy. Guglielmo Marconi and Marconi's Wireless Telegraph Company, Limited, 24, Southampton-buildings, Chancery-lane, London.

14803. Improvement in telephone shells. William Robert Sine and Jacob Sigmund Rosenthal, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JULY 19.

14837. Improvements in or connected with trolleys of overhead electric railway vehicles or locomotives. Robert Wilson Dunn, 15, Water-street, Liverpool.

14847. A continuous covering for electric tramway or railway conduits. Thomas Dewhirst and Robert Burn, 50, Old Broad-street, London.

14879. Improvements in and relating to safety devices for electric motors and the like. The Johnson-Lundell Electric Traction Company, Limited, and John Harper Robertson, 7, Southampton-buildings, Chancery-lane, London.

14889. Improvements in submarine electric cables. Paolo Coridori, 31, Bedford-street, Strand, London. (Complete specification.)

14898. Improvements in the manufacture of filaments for incandescing electric lamps. Jack Crawford Randell, Olun House, Surrey-street, Strand, London.

JULY 20.

11971a. Improvements in and relating to electric current rectifying systems. The British Thomson-Houston Company, Limited, 83, Cannon street, London. (The General Electric Company, United States. (Date applied for under Patents Rule 9, June 1, 1905.)

14905. Disinfector appliance for telephone transmitters. Erbine Curtis Phillips and Fred Earle Shedd, 20, High Holborn, London.

14955. Improvements in the production of long stable electric arcs. James Yate Johnston, 47, Lincoln's-inn-fields. (The Badische Anilin und Soda Fabrik, Germany.)

14959. Improved sparking coil with multiple winding for ignition and like purposes. Société d'Electricité "Nilmelior" and Auguste Michel, 322, High Holborn, London. (Complete specification.)

14964. Improvements in electric hoists and conveyers. Joseph Gershom Childs, Hawthorn-road, Willesden Green, London.

14971. Improvements in and relating to electric switches. Norman Hamilton, 83, Cannon-street, London.

14972. An improved process of obtaining a substance particularly adaptable for making incandescent electric lamp filaments thereof. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

14973. Improvements in mercury vapour electric apparatus. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

14978. Improvement in electric switch. Gustave Leopold Herz, 19, Holborn-viaduct, London. (Date applied for under Patents Act, 1901, Oct. 7, 1904, being date of application in United States.) (Complete specification.)

JULY 21.

15002. Improvements in and relating to electrically-controlled variable-speed gear. Henry Vincent James, 3, Brown-street, Market-street, Manchester.

15017. An improvement applicable to the trolley poles of electric cars. James Stewart Finney, 4, St. Anne's square, Manchester.

15022. Receivers suitable for use in wireless telegraphy or telephony. John Greene Balaillie, 143, Ham Park-road, Forest Gate, Essex.

15045. Improvements in electric train-control systems. August Sundh and Axel Magnusen, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Feb. 16, 1905, being date of application in United States.) (Complete specification.)

15055. An improved process for extracting metals from ores and other metalliferous material by electrolytic means and apparatus therefor. Ganz and Co., Eisengiesserei und Maschinen-Fabrike Act.-Ges., 6, Lord-street, Liverpool. (Date applied for under Patents Act, 1901, Aug. 26, 1904, being date of application in Germany.) (Complete specification.)

15067. Improvements in and relating to the regulation of alternating-current dynamo-electric machines. The Allgemeine Elektricitäts-Ges., 83 Cannon-street, London. (Date applied for under Patents Act, 1901, July 22, 1904, being date of application in Germany.) (Complete specification.)

15071. Improvements in protective devices for electric circuits. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

15074. Improvements in or relating to means or apparatus for regulating the difference of potential between portions of alternating electric current distributing systems. Arthur Francis Berry, 46, Lincoln's-inn-fields, London.

JULY 22.

15084. Improvements in means for enclosing electric switches and pushes, and other apparatus requiring manipulation in a medium from which they must be protected. Christopher Alvey Peck, 6, Bank-street, Manchester.

15091. An improved type of house service fuse-box for the supply or distribution of electricity. Thomas Henwood and Frank Camillo Norman Bergh, 14, Pelham-square, Brighton.

14101. Magnetic tubular hammer. Henry James Dale, 166, Pentonville-road, London.

15121. Improvements in and relating to electric sparking coils. Douglas Elyard Brown, 1, Queen Victoria-street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Aug. 10.

1904.

15703. Means for electrically controlling phonographs and cinematographs in combination. Soc. L. Gaumont et Cie. (Date applied for under International Convention, July 17, 1903.)

15942. Alternating-current electric meters. Union Elektricitäts-Ges. (Date applied for under International Convention July 18, 1903.)

17743 Trolley turners or devices for moving the trolley poles of electric cars. Bamber.

17869. Electric controllers British Thomson-Houston Company Limited. (General Electric Company.)

18012. Processes of oxidation and reduction effected in an electrolytic bath. Imray. (Farbwerke vorm. Meister, Lucius, und Brüning.

19478. Regulators for electric circuits. British Thomson-Houston Company, Limited. (General Electric Company.)

19885. Electric motor controllers. British Thomson-Houston Company, Limited. (General Electric Company.)

26527. Electric ignition apparatus for internal-combustion engines. Eckstein and Coates.

† And 98 miles of interlacing track. a Train mile. b Per mile of single track. A Half-year's figures.

Digitized by Google

NOTES.

Tramways and Light Railways Association.—The *Official Circular* for July contains some useful information concerning light railway orders and a copy of Mr. Bigwood's Vehicles Lights Bill regulating the carrying of rear lights by all vehicles, which Bill was only lost by one vote, and will be reintroduced at a favourable opportunity.

Miniature Electric Lighting Undertaking.—Bridgetown, situate a few miles from Dulverton, Somerset, claims to be the smallest village in England supplied with the electric light. A local wheelwright laid down a plant to supply his own premises. His neighbours expressed a desire for similar illumination, so the wheelwright added to his plant, and is now supplying electricity to others in the village. The population is less than 100.

The Institution.—The issue dated July of the *Journal* of the Institution of Electrical Engineers contains "Stand-by Charges and Motor Load Development," by Mr. A. M. Taylor, with discussion; "Telephone Traffic," by Mr. H. L. Webb, with discussion; "Wireless Telegraphy Measurements," by Messrs. W. Duddell and J. E. Taylor, with discussion; "Low-Tension Thermal Cut-Outs," by Messrs. A. Schwartz and W. H. N. James (Manchester); "Notes on Heating and Sparking Limits in Variable-Speed Motors," by A. H. Bate (Birmingham); and "Commutation in a Four-Pole Motor," by J. K. Catterson-Smith.

"Liberty" a Barrier to "Wireless."—Bartholdi's statue of Liberty, which is constructed of bronze, and surmounts the harbour at New York, is accused of being the obstacle to the reception of wireless messages. Considerable difficulty having been experienced in communicating with the American city, experts were deputed to investigate the cause, and they concluded that the statue acted as a mammoth receiver. If this be correct, it raises a curious position, for the statue at once symbolises the freedom of the Great Republic and imposes a barrier upon science and commerce. It will be remembered that the Eiffel Tower has been similarly regarded with suspicion.

The Metric System.—The secretary of the Decimal Association has received a letter from the general council of chambers of commerce of the Commonwealth of Australia stating that at a meeting of that body held in Sydney in June last the following resolution was passed: "That this general council of the chambers of commerce of the Commonwealth of Australia views with satisfaction the increasing public interest in the metric system of weights and measures, and expresses the hope that it may very shortly be adopted for England and the Empire generally, and recommends that such legislation may now be framed in the Commonwealth as will enable us to at once follow the home country in this change."

Electric Light v. Gas.—The latest contribution to this long-standing debate comes from Loughborough, where electricity has scored a decided success. Hitherto the Market-place has been illuminated by gas lamps of 640 c.p., which apparently have served to accentuate the darkness. Three arc lamps, aggregating 5,700 c.p., have now been substituted at a less cost for lighting than that of the supplanted gas lamps. The arc lamps are of the Union Excello type, giving about 1,900 c.p. each. Midway between the arcs and the ground two 25-c.p. tantalum incandescent lamps are installed on each post, the idea being to burn the arcs till about 11.15 p.m. and then the incandescents only until about daylight, when they will be automatically switched off from the generating station. A similar arrangement has also been installed in Derby-square. A great improvement in the lighting of the districts has resulted, and this is emphasised by comparison with the dismal-looking gas lamps.

Parcels Traffic.—The case of the Manchester Corporation's parcels traffic was mentioned in the Chancery Division on Saturday in connection with interlocutory proceedings in the action instituted by the Attorney-General, at the instance of Messrs. Sutton and Co., to restrain the Corporation from collecting and delivering parcels. The Corporation have statutory powers to carry goods on their cars, and they have adopted the practice of collecting the parcels and delivering them to the consignee's premises, charging a commission for this service. Messrs. Sutton and Co. contend that this extension of the Corporation's carrying powers is *ultra vires*, and the result of the proceedings will doubtless be watched with much interest now that tramway undertakers are paying more attention to goods traffic as a source of revenue.

State Cables and Cheap Telegraphy.—Sir Sandford Fleming, of Ottawa, gave an address at the United Empire Club, London, last week, in which he advocated the formation of an Imperial intelligence department. Sir Sandford said there was a widespread desire to secure a comprehensive means of cheap telegraphy between all the great self-governing British States throughout the world in the interests of trade, shipping, social, and commercial intercourse, and especially in the interests of Imperial affinity and union. No argument had been advanced against the public policy of completing without loss of time the trunk line of telegraph cables, of which the Pacific Cable constituted the first great division, forming as it did a large portion of the whole system of State-owned cables at present projected. He proposed that the cable should be used for a portion of each day to transmit news at a comparatively low rate—10,000 to 12,000 words each week—to be published simultaneously in the chief centres of the Empire. He was assuming the co-operation of the Press in this work. This proposal would be found to harmonise with the suggestions formulated by Sir Frederick Pollock and his friends in the appeal they had made in favour of an Imperial Council combined with an Intelligence Department.

New South Wales Mines.—The annual report of the Department of Mines, New South Wales, for 1904 has just reached us. The information contained, while of great interest to mining engineers, only affects our readers as far as the application of electricity to mining is concerned. We find from the report that coal-cutting machinery has been introduced to a considerable extent into the collieries of New South Wales during the past year. The returns show that seven collieries are now using such machines, and that there is a keen rivalry between electricity and compressed air as the driving medium. Out of the six mines now using mechanical coal-cutters, four have adopted electrical driving and two are using compressed-air machines. The actual number of coal-cutters is 25, and of these 15 are driven by compressed air. The Sullivan electric heading machine and the long-wall machine of the same name seem to find most favour. We should like to see English firms obtaining more orders for this class of plant. Reference is made to the report of the Departmental Committee on the use of electricity in mines issued in England at the beginning of the year, and it is advised that the precautions mentioned in this report should be adopted in the collieries. We notice that the department have instituted an examination for electric motor drivers, on the result of which they issue certificates of competency. The report contains the questions set during the last examination, which show that a good working knowledge of electric machines and of their usual faults is required.

Submarine Cables and Longitude.—The *Observatory* notes the result of a determination of longitude made by officers of the United States Coast Survey through the cable of the Commercial Pacific Company, which joins San Francisco to Manila in the Philippines. Since the laying of this cable completed the telegraphic circuit of the earth it became possible to measure by the ordinary method of telegraphic longitude the arc across the Pacific, and hence to complete the entire circle of the globe. Of necessity this must be equivalent to 360deg., or 24 hours of time, and the interest lies in noting how nearly the sum of the links which go to make up the whole approximates to this total, and thus obtaining some indication of the degree of accuracy which attaches to such operations. There are several routes across the Eastern hemisphere by which the ends of the Pacific cable might be joined, and taking one direct route, *vid* Madras, it appears that the "closing error" is less than a fifth of a second—that is to say, the sum of the various links exceeds 24 hours by only 0·174 second. Another interesting fact comes out. This Pacific cable consists of four sections divided by transmitting stations at Honolulu, Midway Island, and Guam, the total length of cable being 7,846 nautical miles. The time that a signal takes to traverse this length—excluding that occupied by reading and passing on the messages at the intermediate stations—is 0·648, not quite three-quarters of a second.

Test of a Curtis Turbine.—A test was recently carried out upon a 2,000-kw., 900-r p.m. Curtis turbine, built by the General Electric Company of America, the gentlemen entrusted with the proceedings being Mr. F. Sargent (Messrs. Sargent and Lundy, engineers, Chicago) and Mr. Lewis A. Ferguson (vice-president of the American Commonwealth Electric Company). All the instruments used were carefully tested and standardised during the trials, the electrical instruments being tested by representatives of the New York Testing Laboratory. The surface condenser showed practically no leakage. The following is a graphic summary of the results: Full load—Duration of test, 1·25 hours; steam pressure (gauge), 166·3lb.; back pressure (absolute), 1·49in. of mercury; superheat, 207deg. F.; load in kilowatts, 2,023·7; steam consumption per kilowatt-hour, 15·02lb. Half load—Duration of test, 0·916 hour; steam pressure (gauge), 170·2lb.; back pressure (absolute), 1·40in. of mercury; superheat, 120deg. F.; load in kilowatts, 1,066·7; steam consumption per kilowatt-hour, 16·31lb. Quarter load—Duration of test, 1 hour; steam pressure (gauge), 155·5lb.; back pressure (absolute), 1·45in. of mercury; superheat, 204deg. F.; load in kilowatts, 555; steam consumption per kilowatt-hour, 18·09lb. No load—Duration of test, 1·33 hours; steam pressure, 154·5lb.; back pressure (absolute), 1·85in. of mercury; superheat, 156deg. F.; steam consumption per hour, 1,510·5lb. It will be observed that a high degree of superheat was employed. The results taken all round are distinctly satisfactory, and go to confirm the claims made by the manufacturers as to the economy of the Curtis turbines.

Street Lighting in the City.—Our readers are acquainted with the general position of matters between the City of London Electric Lighting Company and the Corporation, and elsewhere in this issue some figures on the subject will be found. The company, who have carried out the illumination of main thoroughfares in the City for several years, were asked by the Corporation in March whether they would be willing to enter into a contract for lighting certain streets with improved lamps. The company asked for particulars of the improvements desired, to which the Corporation replied that a specification would be forwarded. This was not done, and on June 19 the company received an intimation that the Streets Committee had decided to substitute gas for the existing arc lamps, and requesting the company to have the latter removed. The unfairness of this proceeding, both to the company as a commercial concern and to electricity as an illuminant, is obvious. The company has incurred a substantial outlay for street lighting, and the change over to gas implies an annual loss of revenue amounting to over £1,200. As a test of the relative values of gas and electricity as illuminants, it is obviously fallacious to compare what may have been the best electrical apparatus at the time of its installation, nearly 15 years ago, with perfectly up-to-date gas plant. The company point out, moreover, that they did not have a free hand in the selection of either the standards, the lanterns, or the glass of the present electric arc lamps, all of which were settled by the late Colonel Haywood, the then engineer to the Commissioners of Sewers. Considering that the mains and other electrical plant are available, it would have been a comparatively small matter to substitute improved lamps, and as the company are showing a distinctly conciliatory attitude, it is to be hoped that the Corporation will reciprocate this sentiment by responding to the company's proposition for a conference.

The Embankment Scheme.—The ebullitions of public feeling at the actions of our legislators are not invariably a criterion of the sentiment of the community, as they are apt to prove but ephemeral outbursts on the part of a small, if noisy, section; but in the case of the London County Council's Bill to sanction the Embankment scheme the course adopted by the House of Lords in rejecting the measure appears to have aroused a widespread chorus of disapprobation both on the part of the public and the Press. In regard to the latter, this attitude is not confined to those journals which are accustomed to inveigh against every act of the Upper Chamber, but extends to the most Conservative organs. A meeting was held last week at the Surrey Masonic Hall, Camberwell, under the auspices of the local Conservative associations to protest against the course adopted by the Lords. A resolution condemning the action of the peers was altogether inadequate to meet the views of an irate section of the meeting, at whose instance a proposition that the Upper Chamber be abolished was submitted and carried. This step need not, perhaps, be taken very seriously, but it serves to illustrate how embittered the populace have become at the hasty action of the Lords. Had the measure been carefully gone through *seriatim*, and shown to be impracticable and inexpedient, the feeling of indignation might have been allayed; but to throw the Bill out after a brief discussion, when it had been extensively investigated and approved by a committee of the Commons, was rather in the nature of an affront to public opinion. Surely, when that conservative authority the City Corporation had felt constrained to yield its assent, if reluctantly, the scheme merited more detailed consideration than it received at the hands of their lordships. Accustomed to these rebuffs from Parliament in the matter of tramways along the Embankment, the County Council are still undaunted, and will probably bring up another Bill next year, when it will be interesting to observe how far the Lords will persist in their present course.

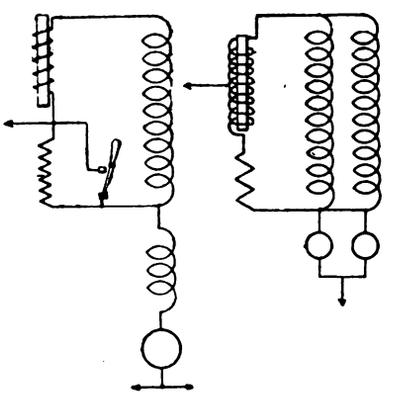
Hull Tramway Returns.—The balance-sheet which has just been issued for the electric tramway undertaking at Kingston-upon-Hull furnishes some valuable figures as to the cost of generation from the tramway station. In our issue for July 7 we reproduced a paper upon charges

Digitized by Google

for supply from combined lighting and traction stations by Mr. J. H. Rider, which showed the figures various tramway undertakings throughout the country have to pay for their current. The argument was in favour of such combined stations, but it is interesting to get figures like those from Hull to show the costs for tramway supply from separate stations. During last year at Hull 3,696,700 units were delivered from the station to the line, and the maximum load on the station was 1,150 kw., which shows a load factor of nearly 37 per cent. The actual figures of costs were as follows: coal, 0·26d.; oil, waste, and water, ·03d.; salaries and wages, ·09d.; repairs and maintenance, 0·08d. This gives a total works cost of 0·46d. as compared with 0·64d. for the year ending March 31, 1904, and 0·94d. for the previous year. In order, therefore, to compare the cost of electricity as supplied to tramways at Hull with the figures in Mr. Rider's paper it is necessary to add the charges for interest and depreciation on the capital expenditure on the station, and also a certain proportion of the management expenses. The accounts are not presented in a form which enables this to be conveniently done, but we see that the capital outlay on the generating station for land, buildings, and plant was slightly over £51,000. The interest and sinking fund charges in Hull average 5·05 per cent., which on the above sum works out at 0·17d. per unit. It will be seen, therefore, that with interest and sinking fund the cost per unit delivered amounts only to 0·639d., and ample provision can be made for management expenses at the generating station and for depreciation on the generating plant without bringing this figure up to that paid in other towns of a similar size. Elsewhere in the accounts we find evidence that the car mileage in Hull is being extended with a corresponding increase in the passengers carried. The total cost per car mile now stands at 7·04d., the income being 9·29d. The increase in the service has slightly reduced this last figure, but the working expenses have come down to a greater extent. The undertaking has paid £11,500 to the city funds for the relief of rates, which is against the policy advocated by strict municipal traders. The tramway engineer at Hull is to be congratulated upon the results obtained from the past year's working.

Air Friction on Trains.—Any information as to the friction which has to be overcome in propelling trains at high velocities is of interest to electrical engineers who have this problem now before them. The high-speed trials carried on near Berlin gave useful figures from actual measurements made at high velocities in the open air. Some experiments made by Dr. A. F. Zahm at the Catholic University of America, at Washington, are described in the *Scientific American*. The chief object of the experiments was to measure the tangential force of air flowing swiftly over even surfaces. The type of surface was varied in order to find what the effect of surface friction was. The experiments were carried on in a laboratory, and, therefore, it was more convenient to move the air at high velocities than to move the object experimented upon. The procedure adopted was to suspend the surface to be experimented on by means of two steel wires in a tunnel through which air was forced at a known velocity. Suitable precautions were taken to ensure that the velocity of the air should be the same at all parts of the tunnel. The length of the surface was then varied in order to divide end friction from the tangential force on the sides of the suspended planes. The results obtained have led to the following conclusions: (1) the total resistance of all bodies of fixed shape and aspect is expressed by an equation of the form $R = a\,v^n$, R being the resistance, v the wind speed, a, n, numerical constants; (2) for smooth planes of constant length and variable speed, the tangential may be written $R = a\,v^{1\cdot85}$; (3) for smooth planes of variable speed, l, and constant width and speed, the friction is $R = l^{0\cdot93}$; (4) all even surfaces have approximately the same coefficient of skin friction; (5) uneven surfaces have a greater coefficient of skin friction, and the resistance increases approximately as the square of the velocity. It will be found that these conclusions agree in general form with those obtained by Froude for water. It can be deduced from the experiments that the friction on a long railway train may equal or exceed the true head resistance, while on a short train or single car the friction is comparatively inconsiderable. Now, though the head resistance may be very greatly reduced by sharpening the front and rear, the skin friction cannot be reduced appreciably by any treatment Hence it is apparent that the total air resistance of a long train or hull cannot be reduced very largely by any treatment, whereas the resistance of a single coach, like a street car or automobile, may be reduced several per cent. by use of suitable prow and stern.

Alternating-Current Motor Used on Direct-Current Circuits.—Two patents have recently been granted in the States to Mr. B G. Lamme respecting alterations in the type of the energy supplied to series-wound motors. When a motor of this description is operated by alternating current, it is desirable that the ampere-turns in the field winding should be relatively low but when it is operated by direct current the magneto motive force of the field current should be much higher in value. In order to provide means for automatically changing the value of the ampere-turns in the field-magnet winding of the motor, Mr. Lamme places in combination with the field coils suitable arrangements of resistances and reactances so as to allow a greater value for the ampere-turns in the field-magnet winding when the motor is operated by direct currents than when it is operated by alternating currents. The methods employed are indicated in the accompanying illustration, which we reproduce from



the *Electrical World* of New York. In one of these methods the field winding is divided into two parts, in parallel with one of which is placed a series circuit containing resistance and reactance. The current is introduced in the series circuit at such a point that when the current is unidirectional the major portion of it flows through both field windings, while when it is alternating only a small part of it flows through the shunted section of the field coil, as shown in the illustration. According to another method, the inventor places in parallel with the whole of the field winding a series circuit containing a resistance and an inductive winding. The current is introduced at a point along the inductive winding so chosen that the proper proportion of alternating current is forced to pass through the resistance and directly to the armature, while the greater relative value of the resistance allows only a small part of any unidirectional current to flow therethrough and forces the greater portion to pass

Digitized by Google

through the field coil. The diagram indicates this arrangement when two motors are operated simultaneously, the field windings being connected in parallel with each other, and the armatures being also connected in parallel with each other.

The Electric Arc in a Vacuum.—In the June issue of the *Physical Review* (New York) Mr. C. D. Child describes some of his investigations at Cornell University on the electric arc in a vacuum and in hydrogen, using different substances as electrodes. The tests were of a somewhat extensive character, and it would occupy too much space to recapitulate them, but the author's conclusions are interesting. With graphite terminals it was found that with pressures less than ·7mm. the drop in potential at the anode became less than that at the anode, and that whenever a glow appeared at the anode the drop there increased from six volts to fifteen. Mr. Child states that there are reasons for believing that this glow is similar to that seen with "Canalstrahlen." At pressures of less than ·7mm. many of the ions appear to move along magnetic lines of force when in a magnetic field. With carbon terminals and with a pressure of ·1mm. the drop at the cathode was somewhat larger than that at the anode. With copper and iron it was found impossible to maintain an arc with pressures of less than about 1mm., unless there was an oxide of the metal on the cathode. Experiments were performed, using graphite for one of the terminals and various metals for the other. When the cathode was graphite the phenomena of the arc were practically independent of the nature of the anode. It was, however, impossible to maintain an arc on a 100-volt circuit with a pressure of less than 1mm. when the anode was graphite and the cathode any of the metals having a high melting point, such as platinum, iron, nickel, copper, or silver. It was very easy to do so when the metal was one having a low melting point, such as antimony, lead, or bismuth. With graphite terminals in hydrogen the drop at the anode was less than that at the cathode for pressures above 400mm., the total drop being much greater than with the arc in air. Between 400mm. and ·7mm. that at the anode was the greater. At pressures less than 10mm. the arc would start on a 500-volt circuit without bringing the terminals in contact, if they were comparatively warm. Under these conditions there were three distinct forms of the arc. With carbon in hydrogen the drop at the anode was much greater than at the cathode. With low pressures four forms of the arc were here observed. No current could be produced by an alternating E.M.F. of 220 volts between iron, copper, or graphite terminals at any pressures. From the experiments it would appear that no theory of the arc is complete which fails to consider the chemical action occurring in the arc. It would also appear that the temperature of the cathode does not alone account for the production of ions there, and their production depends very largely on the melting point of the metal used. The experiments also indicate that with pressures less than about ·8mm. the positive ions driven off from the anode ionise by impact the gas about the anode, while with less pressure this does not occur.

Trains and Tramway Competition.—At more than one railway company meeting during the last few days the wail has been heard that the electric trams are seriously diminishing the traffic on railway suburban lines. Presiding over the Great Eastern meeting, Lord Claud Hamilton stated: "The suburban passenger traffic, other than season-ticket holders, which they were accustomed to see increase by leaps and bounds, had gradually diminished, until in the past half-year they were faced with a falling-off of 1,674,000, representing £19,500, out of the total decrease in passengers of 2,050,014. The cause of this decline was partly bad trade, but it was attributable more to the competition of electric tramways and of the Great Northern and City 'Tube' Railway, and to the creation of additional railway facilities in other parts of London." His lordship proceeded to deprecate the introduction of the new tube to Waltham Abbey, urging, somewhat illogically, that it could have no prospect of success. No allusion was made to electrification. The South-Eastern Company are apparently reconciled to the loss of suburban traffic, and they, too, do not contemplate, at any rate for the present, a resort to the electrification of these lines. At the half-yearly meeting Mr. H. Cosmo-Bonsor announced that: "The number of third-class passengers had decreased by the large figure of 1,499,000, and in money of £13,000. They might attribute that entirely to what was called short-distance journeys, principally in the metropolitan area. The competition to which he had formerly alluded, electric tramways, had drawn a large number of short-distance passengers away from their line through the more convenient form of electric trams, and the principal districts in which they had suffered were Brixton, Peckham, and the neighbouring stations. They could not expect to compete satisfactorily with those electric trams. They, however, had a certain amount of consolation in the fact that the traffic was not particularly profitable, and they had also the consolation that when they came to appeal against the assessments in these particular districts they would be able to plead the competition that had been set up against them for a reduction in the amount of rates they have to pay." Reduced fares do not appear to have furnished a panacea in this instance, as, though the number of passengers shows an increase, the receipts are less. The London, Brighton, and South-Coast Railway also have to deplore a considerable falling-off in their suburban traffic, and the approaching electrification of their metropolitan line will afford an interesting example of the effect of this expedient. The East London Railway, who have also experienced the effects of tramway competition, maintain their policy of sitting on the fence, though the chairman intimated that the line would undoubtedly be electrified ultimately after there had been an opportunity of seeing how the third-rail system worked on the Metropolitan and District lines. The two latter companies, it may be noted, have informed the East London Company that they will cease running over the lines of the last-named company, their successors being the Brighton and South-Eastern Companies. At the meeting of the London, Tilbury, and Southend Railway it was stated that the electrical equipment of the section between the junction with the Whitechapel and Bow Railway at Campbell-road, Bow, and East Ham is finished, and that the District Company's electric trains will shortly be extended to East Ham. There is still a not unnatural disposition on the part of the railway companies to await events in the matter of electrifying their suburban lines, but indications are not lacking that a few years will witness a transition.

British Association.—The remaining contingent, which includes the official section, of the British Association are well on their way to Cape Town on the Union Castle Royal Mail steamer "Saxon" for the annual conference of the association, which, as our readers know, will this year comprise meetings at the chief centres of South Africa. The party includes Prof. G. H. Darwin (president-elect), Sir William Crookes, Sir Benjamin Baker, Sir William Wharton, Sir Richard Jebb, Mr. Alexander Siemens, Profs. J. Perry, W. E. Ayrton, Vernon Boys, D. H. Campbell, H. S. Carhart, and A. R. Forsyth, Major P. A. Mac

Digitized by Google

Mahon, and others, several of the members being accompanied by their ladies. The subjects discussed will cover practically the entire field of scientific research. Prof. Darwin will deliver two presidential addresses, one at Cape Town and the other at Johannesburg. He proposes to review the general principles of evolution, with special reference to inanimate matter. Lord Selborne, the High Commissioner for South Africa, has consented to become one of the vice-presidents of the meeting, and other distinguished South Africans who will co-operate include Sir Charles Metcalfe, Sir David Gill, and the mayors of the chief towns. Another token of the interest taken in the proceedings by the South African Governments assumes the tangible form of a grant of £6,000 towards the official expenses, while the various railways are making substantial reductions to the party in general. Altogether the visit is expected to occupy over 70 days, a good half of which will be spent in travelling, but the admirable method of organisation promises to reduce fatigue to a minimum. All sorts of excursions, scientific and recreative, have been planned. In Section A the subjects will include a paper upon "The Leak of Electricity from Certain Heated Substances," by Prof Beattie, and the same author, in conjunction with Mr. Lyle, will present some "Observations of Atmospheric Electricity in South Africa." Other subjects to be dealt with by the professor are "The Magnetic Survey of South Africa" and "Electrical Conductivity in Relation to Chemical Action." Prof. Perry will contribute a paper upon "The Teaching of Elementary Mechanics," and another upon "The Strength of Winding Ropes in Mines," which will doubtless be appreciated by the large mining industries of those regions. A "Form of Dry Daniell Cell" will receive treatment at the hands of Mr. J. Brown. Section B (chemistry) will be presided over by Mr. G. T. Beilby, whose choice of subject has fallen upon "Gold," and Dr. H. Marshall will discuss "The Experimental Basis of the Dissociation Hypothesis." Colonel Sir Colin Scott-Moncrieff will preside over Section G (engineering), and the chief subject of his address will be irrigation, a theme of much interest to those concerned in South Africa. Sir Colin favours the Italian system of irrigation, which will come in for a high measure of eulogy. Sir Charles Metcalfe's views will doubtless be listened to with great attention, the subjects being the Rhodesian railways and the bridge over the Zambesi at the Victoria Falls, which are to be visited by the party. A paper by Mr. Byles will deal with "Ocean Turbine Boats," and at Johannesburg there is to be a joint meeting of this branch and Section C (geology) for the discussion of important papers on mining, while Prof Ayrton will deliver a lecture upon "Distribution of Power." Section L (educational science) will be under the able presidency of Sir Richard Jebb, who, in his address upon "University Education and National Life," will deal with the growing importance of university education as a factor in national development. The other sections, with which we are not directly concerned, also intend to discuss a great number of momentous questions, and the general indications suggest that the conference will be most successful.

The Liverpool Accident.—In view of the letter written by the signalman Boote acknowledging that the accident was due to an error on his part, it is sufficiently clear that the lamentable tragedy on Friday last on the Liverpool-to-Southport section of the Lancashire and Yorkshire Railway was attributable to the fallibility of the "human equation." The precise manner in which the disaster occurred, as detailed at the inquest, shows that engineering matters had no connection with the fatality, and it was quite immaterial that electricity was the form of traction; a brief attack of mental aberration on the part of the signalman was the cause of the ill-fated passengers being hurried to their doom. When the train to Southport approached Hall-road Station it passed the outer distant signal, which was controlled by a lever numbered 40. It then came to and passed the inner distant signal, which was controlled by a lever numbered 39. After that it came to the outer home signal, which was controlled by a lever numbered 38, and after that to the inner home signal, which was lever 37. All these numbers were consecutive. Then the train came to the cabin and on to the station, and proceeding on the down line to Southport, it went to where the cross-over points back the train, if so desired, from the down line to the middle siding. These points were controlled by a lever in the box which was numbered 23. The signalman went to No. 23 lever and brought it over. When it was in that position he could turn any train that was travelling on the down line into this middle siding. That was the position of affairs. This train, coming from Liverpool, passed the outer and inner distant signals, and it was entitled to pass them whether they were against it or not. If they were not against it, it would come on at ordinary speed. If they were against it, it would come on cautiously. This signalman went to No. 38 lever, but it would not come over unless lever 23 was the other way. Instead of ascertaining that that was the cause, he thought something had gone wrong with the locking gear, and although the outer home signal was against the driver the signalman went to the window and with a green flag brought on the driver, who was bound to obey the order of the signalman, with the fatal result that he was turned into the middle siding, where there was a stationary train. A good deal of criticism has been directed to the influence of the type of coach on the extent of the fatalities. The coaches were of the corridor pattern, and the upper part of one of the coaches of the stationary train was completely separated from the bogie, and precipitated some feet into the air, descending upon the unfortunate passengers in the wreckage of their own car. It has been suggested that in the case of the older pattern of carriage, with its division of compartments and more substantial structure, danger of this kind would have been greatly reduced. Another view of the matter, however, is that in the latter case the peril simply takes a different form, as with the older type of car "telescoping" was almost inevitable. Moreover, it may be noted that in this instance the destruction was restricted to the first car of the express, the passengers in the rear vehicles experiencing nothing beyond a shaking. As remarked above, this deplorable occurrence is shown to be practically a question of the personal element, and this is a factor that can only be specifically regulated up to a certain point; but it seems from this case as if there is room for still greater stringency in rules for the guidance of signalmen in cases of doubt. A question was asked in the House of Commons on Tuesday as to whether, having regard to the damage sustained by the first car, the Board of Trade would consider the advisability of introducing a regulation that cars of this type should be fitted with "some sort of buffer, empty carriage, or other mechanical contrivance in the fore part." Mr. Bonar Law replied that the suggestion would no doubt be dealt with by the inspector in his report after the inquiry, and would be considered by the Board. Such an expedient would mean the consumption of additional power for carrying the dead weight, and a buffer vehicle would need to be placed at the back as well as at the front of every train to afford protection. We are afraid that the waste of power and the engineering difficulties attending a lengthening of the trains will prevent the adoption of any such suggestion unless it can be proved to give absolute safety.

A STUDY OF CIRCUITS CONTAINING RESISTANCE, INDUCTANCE, AND CAPACITY BY MEANS OF THE CIRCLE-DIAGRAM.

BY J. S DOW AND F CREEDY.

The method of the circle-diagram has within the last few years been found applicable to a very large part of the field of alternating-current theory. The following article is an attempt to apply this method to the study of circuits containing resistance, self-induction, and capacity. The constructions made use of do not appear to be given in text-books on the subject, and yet they allow of a treatment much more simple than the analytical one.

The symbols made use of will be as follows:

P.D., applied to circuit, in volts, E;
Capacity, in farads, K;
Self-induction, in henrys, L;
Resistance, in ohms, R;
Current, in impedance, capacity, and main circuit respectively, in amperes, I_1 I_2 I_0;
Frequency of supply, f. $p = 2\pi f$;
Inductive reactance, $x_1 = Lp$;

Capacity ,, $-x_2 = \frac{1}{Kp}$;

Total ,, $x = Lp - \frac{1}{Kp}$.

It may be advisable to begin by defining "reactance," an idea of which we shall make considerable use, but which is not universally employed. Just as the resistance of a circuit is the coefficient by which the current must be multiplied in order to get the P.D. consumed by it, and in phase with itself, so the "reactance" is the coefficient by which the current must be multiplied in order to get the P.D. consumed in quadrature with it. We will term the reactance positive when the P.D. consumed is leading, and the E.M.F. produced, therefore, lagging on the current.

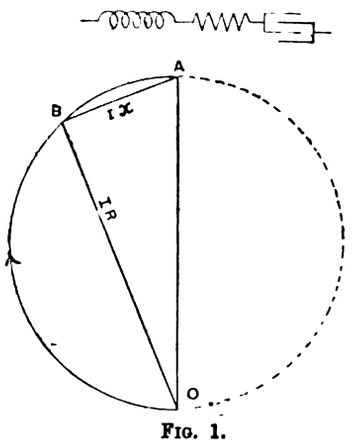

FIG. 1.

The E.M.F. produced by a current I in a self-induction L is ILp, lagging 90deg. on I. Hence a self-induction L produces a reactance $x_1 = Lp$ which is positive. Similarly, the E.M.F. produced in a capacity K is $\frac{I}{Kp}$, leading 90deg. on I. We, therefore, say that a capacity K produces a negative reactance,

$$-x_2 = \frac{-1}{Kp},$$

Thus the total reactance of a circuit containing both capacity and self-induction in series will be

$$x = x_1 - x_2 = Lp - \frac{1}{Kp},$$

which may be either positive or negative.

The circle-diagram is obtained immediately by considering the effect on the current in a circuit containing reactance and resistance in series of varying either of these quantities.

In Fig. 1, O A represents the P.D. applied, E. Then O B will represent in phase and magnitude the P.D. consumed in resistance, I R, and B A the P.D. consumed in reactance, I x, in quadrature with O B. Now, since O A is constant and O B perpendicular to B A, B will travel on the circle O A B however we vary the reactance and resistance, and B A will lead or lag on O B according as our reactance is positive or negative. We are now in a position to follow the change of the current in a circuit containing any combination of reactance and resistance produced by alteration of either of these two variables.

I. *Circuit Containing Resistance and Reactance in Series*—(*a*) *Constant Resistance.*—If we divide through by R, which is constant, the dimensions of Fig. 1 will be reduced R-fold, but the angles will remain the same. We thus arrive at

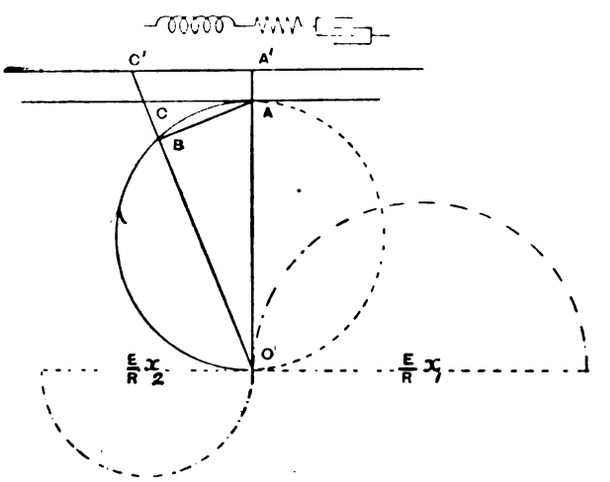

FIG. 2.

Fig. 2. O B is now the P.D. consumed in resistance divided by the resistance, and, therefore, represents the current I_1 in magnitude. Also the angle A O B will represent the angle of lag, for the tangent of this angle is still $\frac{Lp}{R}$. The *locus* of I_1 will, therefore, be the semicircle O A B, and its maximum value, corresponding to no reactance in the circuit, will be $\frac{E}{R}$, in phase with the P.D, which is represented by O A. (In the above we have assumed, for the sake of simplicity, that we are dealing with positive reactance only. If our reactance is negative, I_1 may also travel on the semicircle shown dotted.)

We can now deduce a simple construction, by means of which the current corresponding to any value of x may be found. Draw A C tangential to the circle O A B at A, and produce O B to meet it at C. Now, since the triangles A O C, A O B are similar,

$$\frac{AC}{AO} = \frac{AB}{OB} = \frac{x}{R}, \text{ and hence } AC = \frac{Ex}{R^2}.$$

A C is thus proportional to x, and the intercept A' C', on any line parallel to A C, will clearly be proportional to x also. We thus obtain the following construction: Set off the reactance along any line A' C' to a convenient scale. Set off the resistance from A' along a line A' O perpendicular to A' C', to the same scale. To *any* convenient scale set off O A, along O A', to represent $\frac{E}{R}$. Describe a circle on O A as diameter. Draw a line, O C', cutting the circle in B. O B will now represent the current corresponding to A' C', to the same scale as that to which $\frac{E}{R}$ is represented by O A. If, as assumed above, our reactance is entirely of a positive character, our construction enables us to find the current for any value of L if the frequency is constant, or for any value of p if L is constant.

Turning to the more general problem in which reactance may be either positive or negative, it is of interest to observe the variation in the P.D. across the self-induction and capacity respectively. If we have a constant inductive reactance and a variable capacity reactance, the P.D.

Digitized by Google

across the self-induction (equal and opposite to the E M F. of self-induction) will be proportional to the current, and lead it by 90deg. Thus it will move on a semicircle of diameter $\frac{E}{R} x_1$, as shown in Fig. 2. Similarly, if we vary the inductance, the P.D. across the capacity will travel on the semicircle of diameter $\frac{E}{R} x_2$.

(*b*) *Constant Reactance.*—Reasoning as before, we see that if we now take A in Fig. 1 as our origin and divide through by x, which is constant, A B will represent the current in magnitude, but now not in phase, for the angle of lag is the complement of the angle O A B. We must, therefore, rotate the vector O A through 90deg., thus arriving at Fig. 3, in which A T represents the P.D., E. Therefore the angle B A T (which is equal to 90deg. – A O B) may now represent the angle of lag, and thus A B will represent the current in phase and magnitude. The *locus* of I_1 is,

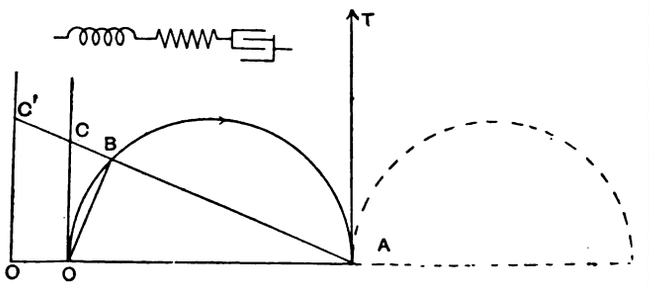

FIG. 3.

therefore, the semicircle A O B, and its maximum value $\frac{E}{x}$, corresponding to zero resistance, is represented by A O. Clearly an exactly analogous construction to that introduced in I.(*a*) may be applied here. If O′ C′ represent any resistance, R, A B, obtained in the same manner as before, represents the corresponding value of I_1 to the same scale as that to which O A represents $\frac{E}{x}$. A combination of these two constructions enables us to find the current for any resistance and reactance if both are varied.

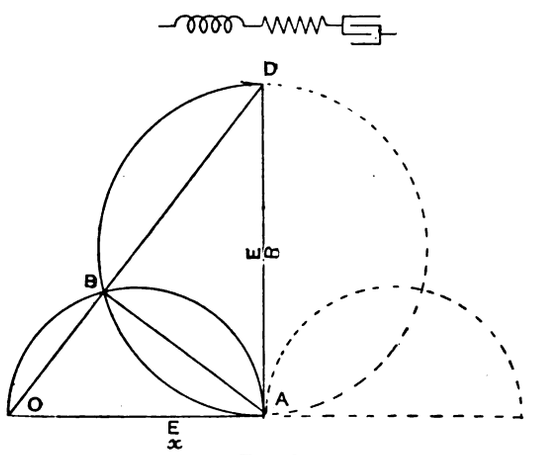

FIG. 4.

(*c*) *Resistance and Reactance both Variable.*—In Fig. 4 the current A B travels on the semicircle A B D, the diameter of which is $\frac{E}{R}$, for variable reactance, and on the semicircle A O B, the diameter of which is $\frac{E}{x}$, for variable resistance. Therefore, if both R and x have certain values given to them, the corresponding value of the current must be A B, which is drawn from the origin to the intersection of the two circles. This construction can be still further simplified.* O B and D B are both perpendicular to A B, and O D is, therefore, a straight line. The construction is, therefore, as follows: Set up A D = $\frac{E}{R}$. Draw A O = $\frac{E}{x}$ perpendicular to A D. Join O D. Through A draw A B perpendicular to O D. Then A B represents the current, corresponding to a reactance x and a resistance r both in phase and magnitude.

We now come to the consideration of circuits containing impedance and capacity in parallel. We shall find that the variation of self-induction, resistance, capacity, and frequency respectively give rise to four distinct cases

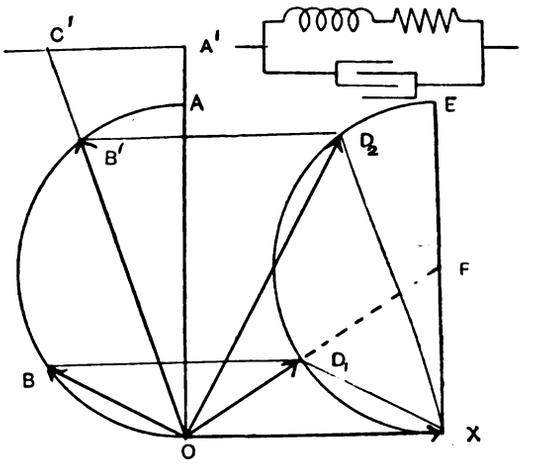

FIG. 5.

II. *Capacity and Impedance in Parallel.*—(*a*) *Variable Self-Induction.*—In Fig. 5, O A represents $\frac{E}{R}$ as before, and the *locus* of the choker current, I_1, is the semicircle A O B. O X perpendicular to O A represents the condenser current I_2 in phase and magnitude. Combining each value of I_1 with I_2, we get the *locus* of I_0, the current in the mains, which is

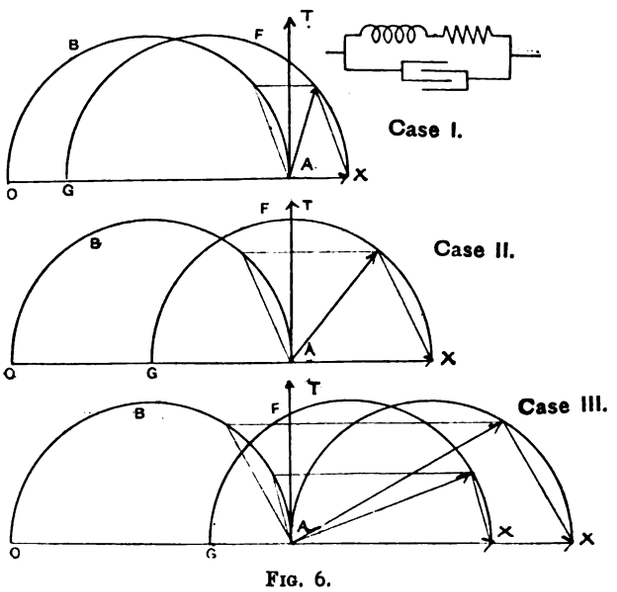

FIG. 6.

represented by O D_1, O D_2, etc. As O X is constant throughout, the *locus* of the points D_1 D_2 . . . is clearly the semicircle X E D, the diameter of which is $\frac{E}{R}$, and the centre, F, of which is removed a distance O X to the right of G, the centre of the circle O A B. From this figure it is evident: (1) That the main current will either lag, lead, or be in phase with the P.D. according as $I_2 = E K p$ is less than, greater than, or equal to $\frac{E}{2R}$. Therefore, if $2 K p R$ is greater than 1, the main current must always lead whatever value we give L. (2) That I_0 is a minimum when O D produced passes through F, and this is the case when the tangent of the angle of lead = $2 K p R$. The value of

* This simplification was pointed out to one of the authors by Mr. L. I. Solomon, a student at the Central Technical College.

Digitized by Google

L corresponding to this is easily deduced direct from the figure, and is given by the well-known relation

$$L = \frac{1 + \sqrt{1 + 4KR^2p^2}}{2Kp^2}.$$

It is interesting to note that the minimum value of the main current must always lead on the P.D. It might have been supposed that the main current which supplies the losses in the choker would be least when in phase with P.D, but it must be remembered that an increase of L, while it puts the main current more out of phase, also decreases the choker current, and hence the choker losses. An application of the construction previously described would enable the value of I_0 for any value of L to be found.

(*b*) *Variable Resistance*.—Our diagram is now a modification of Fig. 3, arrived at in a similar manner to Fig. 5. In Fig. 6, as before, the semicircle A O B is the *locus* of I_1, and A T represents the P.D., E, applied to the circuit. Then, if A X represents the constant capacity current, I_2, I_0 will travel on the semicircle A F G, the diameter of which is $\frac{E}{L\,p}$, and the centre of which is moved a distance A X to the right. Three distinct cases now occur, and these are tabulated below:

		Value of I_0.	
		R = 0.	R = ∞.
Case I.—			
$EKp < \frac{E}{2Lp}$	I_0 may lag, or lead, or be in phase with E	Max.	Min.
Case II.—			
$EKp = \frac{E}{2Lp}$	Ditto, ditto	$I_0 = EKp$	$I_0 = EKp$
Case III.—			
$EKp > \frac{E}{2Lp} < \frac{E}{Lp}$	Ditto, ditto		
$EKp = \frac{E}{Lp}$	I_0 always leads, except when R = 0, and is then zero and in phase with E	Min.	Max.
$EKp > \frac{E}{Lp}$	I_0 always leads		

The chief point of interest brought out in this table are that the maximum and minimum values of I_0 occur when the resistance is either 0 or infinity. It is also to be noted that in case II. we have a constant main current for all values of R. Here, again, the application of the construction given in I (*b*) enables us to find the main current for any value of R.

(*c*) *Variable Capacity*.—This case appears to be the most usually considered of the four, probably because it is the simplest. Following our usual nomenclature, it is clear that if I_1 is presented by O B in Fig. 7, and O X_1, O X_2

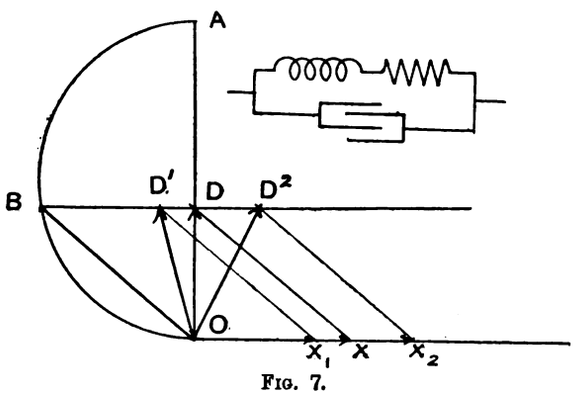

Fig. 7.

. . . represent the variable values of I_2, O D, representing I_0, must travel along the straight line B D_1. I_0 is, therefore, a minimum when O D is perpendicular to B D, and the condition for this is

$$\frac{E \cdot L\,p}{R^2 + L^2p^2} = EKp.$$

Hence the required value of K making I_0 a minimum is given by

$$K = \frac{L}{R^2 + L^2p^2}.$$

I_0 will then be in phase with the P.D. and equal to the "useful" current in the choker. Clearly, also, if K exceeds this value I_0 will lead, if K is less than this value I_0 will lag.

We now come to the last case—that of variable frequency. The problem is now complicated by the fact that a change of frequency affects capacity and inductive reactance in different ways.

(*d*) *Variable Frequency*.—As before, O A represents $\frac{E}{R}$, and A' C_1', A' C_2', . . . may now be taken to represent the frequency to any convenient scale. The *locus* of I_0 can now be found by the following construction: By joining C_1', C_2', . . . to O we get O B_1, O B_2, . . ., the corresponding values of I_1. Let O X_1 represent the value of I_2 corresponding to A' C_1'. Join C_1 x_1, cutting O A at P. Then the lines C_1' x_1, C_2' X_2, . . . drawn through

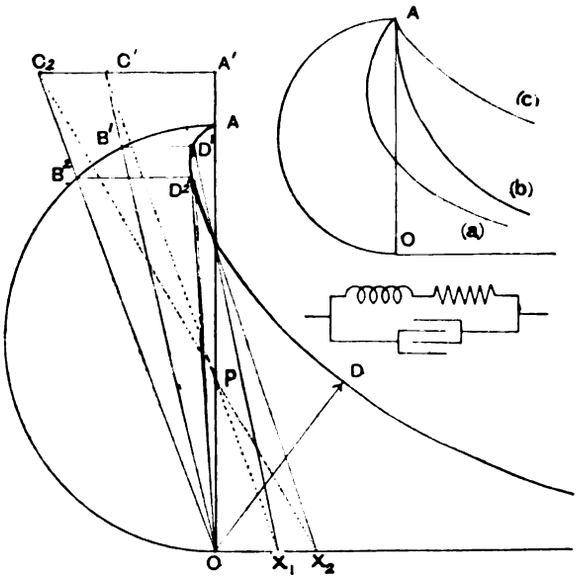

Fig. 8.

P_1 will cut O X in points X_1, X_2, . . . giving O X_1, O X_2, . . . , the corresponding values of I_2. Combining the corresponding values of I_1 and I_2 in the usual way we get the curve A D_1 D_n, which is the *locus* of I_0. The curve passes through the point A, and is asymptotic to the axis O X. The minimum value of I_0 will be O D normal to the curve, and this value of I_0 will lead on the P.D. The value of p for which I_0 is a minimum can be shown to be

$$\frac{1}{L}\sqrt{\frac{(L^2 + 2KLR^2)^{\frac{1}{2}}}{K}} - R.$$

This curve may, or may not, cut the axis O A. Clearly the same condition as in II.(*c*) will determine this. Hence I_0 will lag if $E\frac{Lp}{R^2 + L^2p^2}$ is less than I_2—*i.e*, if p is less than $\frac{1}{L}\sqrt{\frac{L}{K} - R^2}$. Now, if R is less than $\sqrt{\frac{L}{K}}$, this condition can be fulfilled, and we then get curve (*a*) in Fig. 8. I_0 will now lag for certain values of the frequency. If $R = \sqrt{\frac{L}{K}}$, we arrive at curve (*b*), which is tangential to O A at A. I_0 must now always lead except when the frequency is zero. Finally, if R is greater than $\sqrt{\frac{L}{K}}$, we arrive at curve C_1 and in this case also I_0 must always lead, for the only value of the frequency which brings I_0 into phase with the P.D. is zero.

We have now considered the alteration of the different variables for elementary combinations of reactance and resistance. In these constructions the usual assumption that we are dealing with sine waves has been adopted. The results would also require modification if iron losses in the choker, and dielectric hysteresis or leakage losses in the condenser, were taken into account.

THE JOHNSON-LUNDELL REGENERATIVE CONTROL FOR TRAMCARS.

On Thursday last week the latest Johnson-Lundell-Lang regenerative double series-paralleling, automatic braking control system for electric tramcars was shown to a party of engineers at the Southall works of the Johnson-Lundell Company. The apparatus shown is a further development of the compound regenerative control system tested on the Newcastle tramway system in 1902. It is similar to that in so far as the general construction of the motors is concerned, but the method of control has been improved.

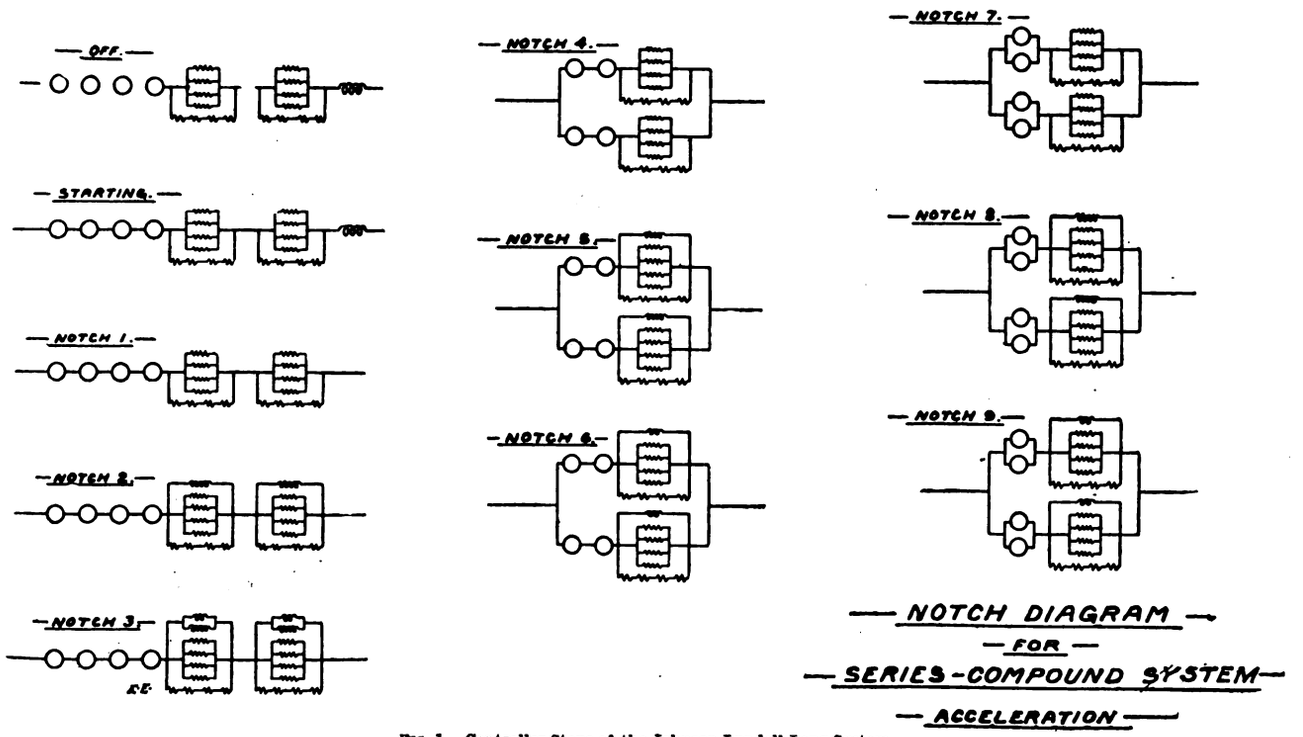

FIG. 1.—Controller Steps of the Johnson-Lundell-Lang System.

Coming now to the regenerative braking arrangements, it should be remembered that Mr. Lundell's original system was designed for compound-wound motors. In July, 1902, there was made in Newcastle elaborate tests of this all-compound regenerative system. These tests were made under the critical direction of Mr. H. F. Parshall, who, in

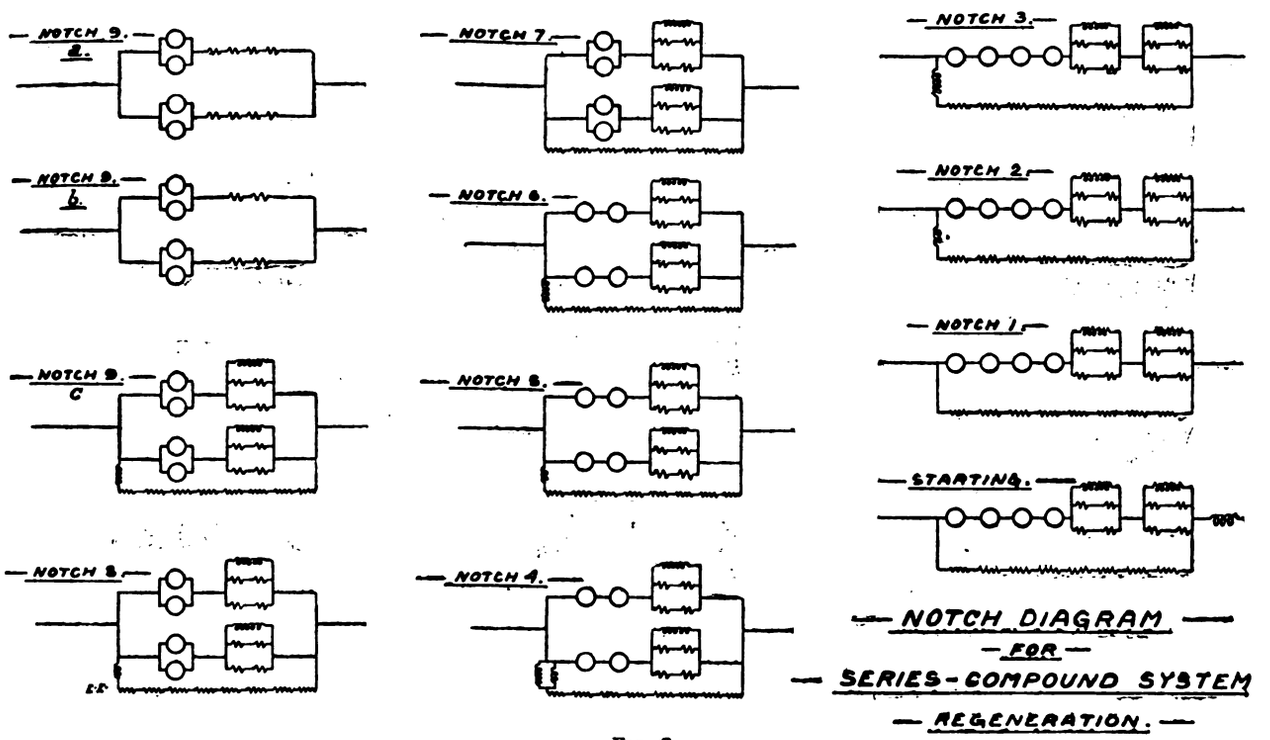

FIG. 2.

Thus there are still two motors employed per car, and each motor has a double-wound armature with two commutators. This enables the four armature circuits to be connected in series when starting, and all in parallel when running at high speeds. The advantage of this is that it increases the number of economical notches in the control and prevent loss of energy in resistance. As will be seen from the diagram of connections for the different notches of the controller, resistance is only used in series with the motors in the first position. This feature has been described before in our columns, and we shall not go into the details again except to mention that a saving of 15 per cent. is claimed from the abolition of main circuit resistances.

a subsequent explanatory note upon his report, observed that whereas the system was entitled to claim an input of some 15 per cent. less than that demanded by the single series-parallel system, and to a recovery through regeneration of about 25 per cent. of the input, the net saving over the standard system was, nevertheless, not more than 25 per

Digitized by Google

cent. Mr. Parshall gave as a reason for this apparent inconsistency the fact that the shunt losses during the time of accelerating and running were about equivalent to the 15 per cent. saved by double series-paralleling the circuits. In the new apparatus this shunt loss has been avoided by a device designed by Mr. G. Lang, the engineer of the Johnson-Lundell Company. This is done by connecting the motors as series machine for acceleration and running, and by switching over certain coils to act as a shunt circuit when regenerating. Other series coils are still retained, so that the machines act as compound-wound

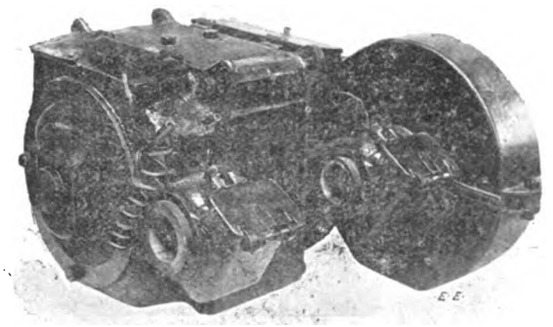

FIG. 3.—Tramway Motor with Laminated Field.

dynamos with the series coils opposing the shunt when they return current to the line. This is effected by suitably grouping the several windings in the required series or parallel relations through the medium of a third automatic controller, worked by pressing a button on the main controller handle. This third controller, or "field changer," is operated automatically by means of a solenoid so arranged as to oscillate its contact cylinder against the retractile force of a clock spring. The spring holds the cylinder in what may be termed its normal position, in which position it gives to the equipment its series or motor characteristic. When it is oscillated therefrom by the action of the solenoid, the

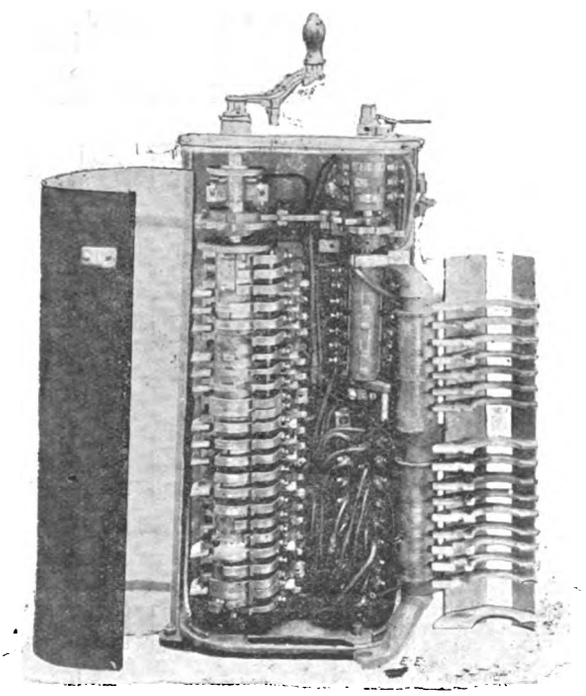

FIG. 5.—Controller.

equipment is given its compound or regenerative characteristic. The solenoid operating the field changer is controlled through contacts in the platform controllers, the circuit being closed by the driver's thumb pressing upon a button fixed in the top of the controller handle.

Fig. 1 shows the connections of the motors for the different positions of the main controller handle when accelerating. In studying these it must be noted that the zigzag lines represent field coils, the grouping of which can be altered, and the spirals represent resistances. Thus, while resistance is only put in the main circuit when starting, it is used to shunt the series field windings to regulate the speed on notches 2, 3, 5, 6, 8, and 9. If this controller handle is simply moved back after full speed is obtained, no regenerative action is set up by the series motor.

When, however, the button on the controller handle is pressed, the motors become compound machines, and the connections are as shown in Fig. 2. The motors are then caused to develop a braking effort from step to step as the handle is moved backwards, in the same graduated way as they developed the propelling effort in accelerating when the handle was moved forward. The compounding is so proportioned as to effect a gradual braking effort. The

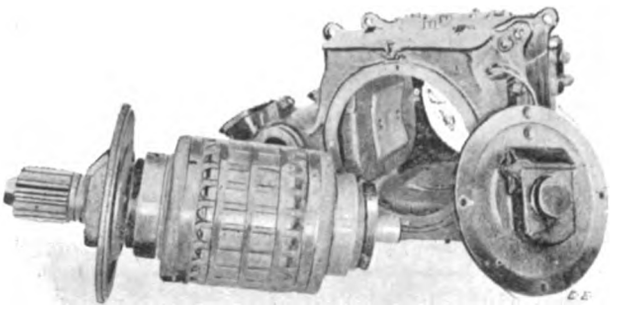

FIG. 4.—Motor with Armature Removed.

series ampere-turns acting in opposition to the shunt ampere-turns tend to decrease the braking capacity as the armature current rises, thus effectually preventing an excessive braking effort. The desired braking effort for each controller position is effected by varying the shunt ampere-turns; extra contact fingers on the platform controllers effect this variation of the ratio of series to shunt ampere-turns. These extra fingers are brought into play by means of the automatic controller; those effecting the changes of field strength for accelerating purposes being at the same time and by the same means put out of action. In this way not only has the efficiency of the system been materially increased through the elimination of the shunt losses indicated by Mr. Parshall, but there is also the advantage of having series-wound motors for acceleration. The confining of this compound working to the regeneration only enables the relative proportions of the shunt and series turns to be properly adjusted to give smooth braking which could not be done when the motoring was done with the same com-

FIG. 6.—The Johnson Brake Band.

pound machine. For the same reason it has now become practicable to operate the car with but one motor in case of need. A characteristic of Mr. Lang's method of field control of great value is that the field is always maintained by more or less series excitation, consequently the shunt coils are never subjected to the disruptive stress of an inductive discharge, and may be manipulated with as complete immunity from sparking as are ordinary series windings. This was apparent from the trials we witnessed, where no sparking whatever was to be seen on the automatic field-changing controller.

The motor used (Figs. 3 and 4) are of the usual four-pole

Digitized by Google

type, and are suspended in the usual manner. They are, however, as has been indicated, fitted with armatures having divided windings and two commutators. The field magnets are of the laminated type instead of the usual castings. The series and shunt windings are so arranged as to require but little more winding space than is usually allowed for series windings alone. The platform controllers (Fig 5) are of the standard series-parallel type, and differ therefrom only in that they are fitted with the additional contacts required for double series-paralleling, and have fitted into their handles a button lever switch for operating the contacts which control the "field changer." The automatic controller, or field changer, is located underneath the car in an accessible position between the motors.

The braking function of the regenerative motors we saw ceases when the car speed falls to about two miles per hour. It then becomes necessary to bring into action a mechanical or other brake to stop the car and to hold it

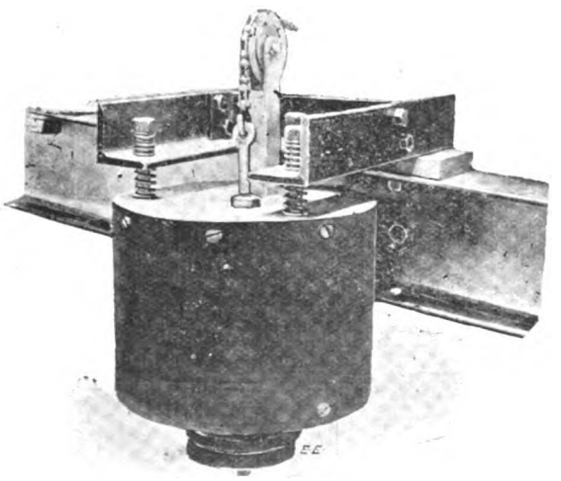

FIG. 8.—Solenoid for taking off Brakes.

when on a grade. This was done by a supplemental braking system, which has been invented and developed by Mr. Edward H. Johnson, and which, though purely mechanical, is, nevertheless, controlled electrically. The power to operate it is obtained from the car axle, as in the case of regeneration. Accurately speaking, this invention is not a brake, but rather a method of utilising the kinetic energy of the car to apply whatever brakes may be employed. It is equally applicable to wheel shoes or track slippers. The adaptation we illustrate is to the ordinary wheel-shoe system of a standard four-wheel tramcar, the entire braking mechanism of which is retained, and may, in addition to the special control to which it is subjected, be operated by hand in the usual way. To the end of the regular braking lever there is attached two stout steel-wire cables; these are led to one of the axles, and there attached to the respective ends of a specially designed resilient spiral friction band (Fig. 6), which band is given about five turns around a drum on the car axle. Normally this band is by its own resilience maintained in open form, and, therefore, free of the drum, and inoperative; but should a pull be exerted upon

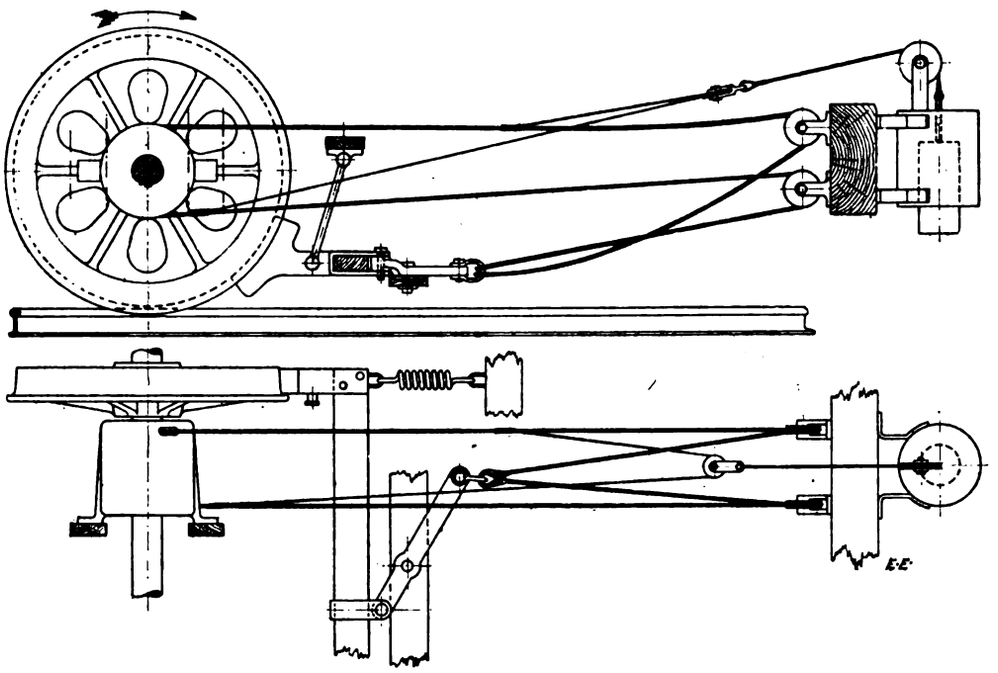

FIG. 7.—The Johnson Patent Braking System as applied to Ordinary Brakes on Car Wheels.

its two ends and its resilience overcome, it will wind up on the axle and exert a pull upon one or the other of the brake lever cables according to the direction of the axle rotation. The value of this pull will be the friction value of the five turns of the band derived from the pull or drag that is being exerted by the weight, or other force, employed to overcome the resilience of the spiral and initiate its winding action. Whatever excess this force may have over and above that required to overcome the spiral resilience becomes a drag on the "free" end of the spiral, and determines the value of the pull on the brake lever (Fig. 7). The form of force now employed for exerting this initial pull and subsequent drag is a weight; attached to this weight is a pulley, and around this pulley a small steel cable, the ends of which are attached to the respective ends of the spiral band. The weight becomes in turn the plunger of a solenoid which serves to hold it in suspense, thus relieving the strain on the spiral band and supplying the potential energising factor.

The solenoid (Fig. 8) is controlled by contacts in the platform controllers so located as to cause the weight to be lifted in advance of the starting moment of the motors, and maintained in suspense until the controller is again returned to the "off" position or should the current to the car be interrupted. In such event the solenoid, of course, loses its energising force and its plunger falls, thereby applying the brakes. In the event of the failure of the prime current supply from any cause, as, for instance, a stoppage of the power, a broken supply conductor, the loss of trolley contact, or any disablement of the equipment itself, the brakes promptly come on and the car is stopped. This is a valuable feature of the automatic braking system.

The results of the tests made on the circular track at Southall were satisfactory, everything working smoothly. It was admitted that a considerable amount of complicated apparatus was needed over and above the ordinary equipment. Commercial experience can alone decide whether the cost of maintaining this apparatus will be excessive. The working of the car is simple, and it is claimed that the failure of certain details will not prevent the motors being run as series motors. The regeneration is optional as far as the driver is concerned, but he obtains a braking

Digitized by Google

action readily, as the controller is moved back, by the pressure of a button in the handle he is already gripping. It would seem, therefore, that it will be easier for him to work the car on economical lines, and the car driver may be relied on to work his car in a way most convenient to himself. We understand that a commercial trial for the system is being arranged.

A TRACTION MOTOR FOR CONTINUOUS AND ALTERNATING CURRENT.

In a recent issue the *Elektrotechnische Zeitschrift* described a car supplied by the Allgemeine Elektricitäts-Gesellschaft for the Niederschöneweide Ostend (Cöpenick) tramways. This car is equipped with motors of the Winter-Eichberg type, which can be driven either by continuous or alternating current. For compact systems of town tramways continuous-current working has been found best adapted, but where outlying branches or connecting links are concerned the advantages offered by alternating current become apparent, enabling, as it does, economies to be effected in the initial outlay and a reduction of the transformer losses. By working such branches or connecting links with alternating current it is possible to convey high-tension current to the feeding points, and there

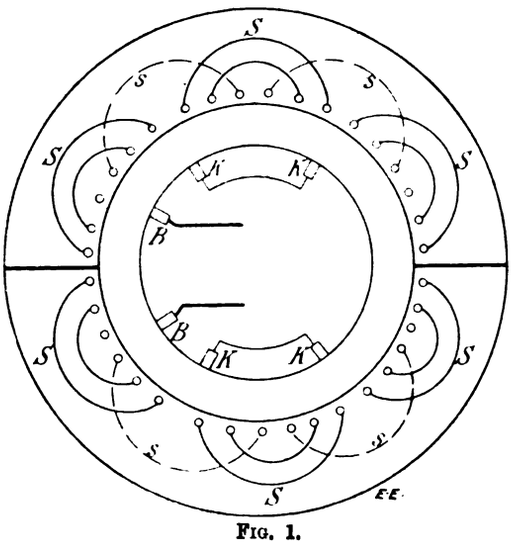

FIG. 1.

transform it down by means of static transformers to the pressure required for the motors. These transformers need no attendance, and have a considerably higher efficiency than converter stations. Or it is possible to convey the high-tension alternating current to transformers attached to the cars themselves.

On the tramways system in question continuous current was originally the only supply available, so that a transformer sub-station had to be provided. The line is usually worked with continuous current throughout its length. But to enable the experimental car to be driven also with alternating current, a small transformer station equipped with a motor-generator has been erected in a central position. The motor is supplied with current from the westerly portion of the overhead trolley wire, and drives an alternator which furnishes single-phase alternating current through transformers to the easterly half of the trolley line. The two halves of this line are divided by a short section of dead conductor. By regulating the speed of the motor-generator the frequency of the alternating current can be varied between 25 and 40 periods at from 400 to 640 volts pressure. The pressure of the continuous-current supply ranges from 500 to 550 volts. This experimental installation covers all the conditions which would obtain in the case of an interurban and urban tramways system, the small transformer station representing the town boundary, at which point the change from continuous-current to alternating-current working would take place in the ordinary way. In passing this point the driver has only to shift a lever on the controller from one position to another. Should he fail to effect the change at the right moment no damage would, however, result, the car in that case simply losing most of its driving force, and thus drawing attention to the omission. The car is equipped with two motors wound for a continuous-current pressure of 250 to 275 volts, so that with a line pressure of 550 volts they must be run in series. Hence for continuous-current working only series connection with resistance regulation at the controller is provided. The motors differ, however,

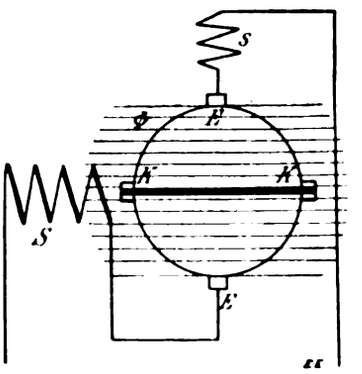

FIG. 2.

from ordinary continuous-current machines in that they have laminated fields to enable them to be worked with alternating current. They are six-pole machines of the Winter-Eichberg type.* The collector has six brushes, of which two are exciting and four short-circuiting brushes. The diagram of the winding is shown in Fig. 1, K being the short-circuiting and B the exciter brushes respectively. The coils S in the stator are the ordinary coils of the Winter-Eichberg motor, while the coils *s* constitute an auxiliary winding for the purpose of continuous-current working. Since the armature is provided with series drum winding, the compensating coils, *s*, do not require to be distributed uniformly over the whole circumference. This enables the casing to be arranged in the ordinary way for traction motors. Naturally it would be possible to dispense with the coils *s* by disconnecting the short-circuiting brushes when running with continuous current. But as this would introduce a further complication into the controller, Herr Eichberg preferred to compensate the action of the short-circuit current in the armature by means of the coils *s*. For the rest it may be observed that the turns in these coils correspond in number to those in the armature winding, but they carry a smaller volume of current, since less

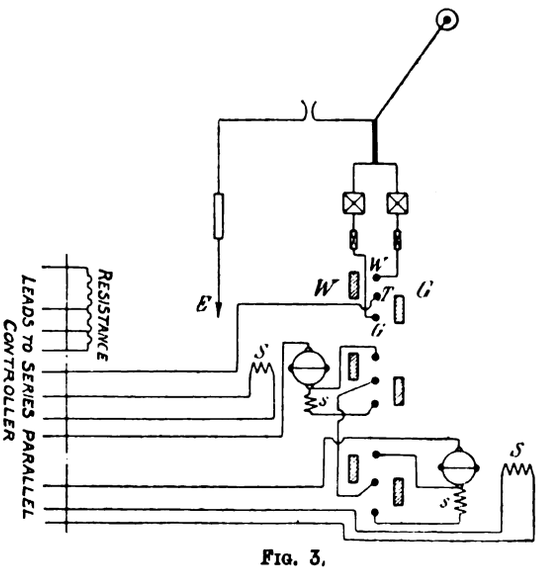

FIG. 3.

is taken when driving with continuous current than with alternating current. The effect of the coils *s* may be explained with the aid of the diagram (Fig. 2) which represents a two-pole arrangement. The only field which really passes through the armature is the active magnetic field, ϕ, represented in the diagram by horizontal lines. Were the coil *s* not provided, the armature would

* See full description, *Electrical Engineer*, vol. xxxiii., p. 357, etc.

Digitized by Google

generate a vertical field which would induce a current between K K. As in Fig. 1, K K are the short-circuiting brushes and the exciter brushes are marked E E. S is the main winding in the stator and s the compensating coil required for continuous-current working. When running with alternating current the compensating coils are cut out at the controller. With continuous current, on the other hand, the brushes, E E, are connected in series with the compensating winding, it being in this way ensured that the compensating field is always exactly proportional to the armature current. Commutating poles are not used, despite which fact commutation both with continuous and alternating current is as sparkless when starting and running as with an ordinary continuous-current traction motor. The speed of the car is from 15 km. to 20 km. per hour when the continuous-current supply is used and from 25 km. to 35 km. per hour according to the periodicity, when the motors are receiving alternating current. This is in accordance with practical requirements, since a higher rate of speed is permissible out of town. Fig. 3 is a diagram of the connections in the car. Each circuit is provided with an automatic cut-out. It is, however, intended in future cars of the type to employ only one such device to serve both for the continuous and alternating current circuits respectively. The controllers resemble those of standard series-parallel type. Combined with each is a two-way switch, W G, which serves to change over from one system to the other as required. The windings s are also cut in or out through this switch. The armatures remain in series at all positions of the controller, while the stators may be connected in series or parallel through the main lever. A mechanical attachment actuated through the lever of the switch, W G, ensures that the stators are in series when continuous current is being supplied to the motors.

LABOUR SAVING FORMULÆ.*

In the Design of Direct-Current Dynamos, especially with regard to High Speeds.

BY JULIUS FRITH, A.M.I.E.E.

The use of formulæ by the elementary student is indefensible; it is only when actually engaged in the commercial design of machinery that it is allowable to take short cuts as labour-saving devices. There is one other argument for the use of formulæ, and that is, that by representing the complicated conditions that arise in the design of electrical machinery in some simple comprehensive manner, a clearer idea is obtained of the mutual relation of the various quantities involved, a truer perspective is gained, and the wood sometimes ceases to be hidden by the trees. For the sake of clearness we shall take multipolar generators, with as many circuits as poles—*i.e.*, parallel, or "lap" wound—and as many commutator bars as armature convolutions.

Let D = diameter of armature in inches;
d = diameter of commutator in inches;
n = number of convolutions and commutator bars;
b = thickness of a brush in inches;
P = number of poles and armature circuits;
l = length of armature between end plates in inches;
C = current per circuit in amperes;
A = total current in amperes;
V = terminal volts;
R = revolutions per minute.

The chief constants of a generator are, after the volts, amperes and revolutions per minute.

The KW. per 100 r.p.m. $= \frac{V A}{10 R}$;

the armature ampere-turns per inch diameter

$$= \frac{C \times n}{D} = \frac{A \times n}{P \times D};$$

the armature ampere-turns per pole

$$= \frac{C \times n}{P} = \frac{A \times n}{P^2};$$

the average volts per commutator bar

$$= \frac{V \times P}{n};$$

the peripheral speed of the commutator

$$= \frac{\pi d R}{12} \text{ feet/min.};$$

the peripheral speed of the armature

$$= \frac{\pi D R}{12} \text{ feet/min.};$$

and the reactance voltage of coil under commutation.

All these, with the exception of the reactance voltage, can be expressed quite simply in terms of symbols in the above list, and require no proof.

The formula for the reactance voltage is obtained from the following considerations:

Number of convolutions under commutation at one brush

$$= \frac{\text{thickness of brush}}{\text{pitch of commutator bars}} = \frac{b \times n}{\pi \times d} = N.$$

In one gap there are conductors under commutation from two brushes; the magnetising force of which = 2 N C ampere-turns.

If K = the lines due to one ampere-turn for each inch of slot parallel to the shaft, then lines set up due to commutation

$$= 2 N C K l = F.$$

The direction of the current is changed once only ($= \frac{1}{2}$ cycle) whilst passing under one brush, hence the frequency of commutation

$$= \frac{1}{2} \times \frac{\text{peripheral speed of comm.}}{\text{thickness of brush}} = \frac{\pi d R}{2 \times 60 \times b} = \sim.$$

Volts induced in each turn $= 2\pi \sim F \times 10^{-8}$,
i.e., reactance volts of the coil under commutation
$= C . K . l . R . n \times 0{\cdot}105 \times 10^{-8}$.

Now the armature reaction in ampere-turns per inch diameter

$$= \frac{C \times n}{D}.$$

Putting this value into the above equation,

Volts reactance
$= A.T. \text{ per 1in.} \times R . l . D . K . \times 0{\cdot}105 \times 10^{-8}$.

Now, for a machine to stand, say, 25 per cent. overload with fixed lead, the armature ampere-turns per 1in. diameter should not exceed 1,000, and the reactance voltage should not exceed 5. K, for parallel slots, can be taken = 28. From these

$$R \times l \times D > 240{,}000.$$

N.B.—It is interesting to notice that this is really a limit to the area swept out by an active conductor per second, which

$$= R \times l \times D \times \frac{\pi}{60} \text{ sq. in.}$$

Now by simple arithmetic the diameter of the armature

$$= \frac{\text{volts} \times \text{amperes}}{\text{ampere-turns per 1in. diameter} \times \text{volts per comm. bar}}.$$

Now, the volts between adjacent commutator bars should not exceed, say 10, *i.e.*,

$$\frac{V \times P}{n} > 10;$$

taking this in conjunction with armature ampere-turns per inch diameter not exceeding 1,000

$$\frac{A \times n}{P \times D} > 1{,}000,$$

and putting in the two limiting values we have

$$D < \frac{KW.}{10}$$

That is, if the kilowatt output exceeds 10 times the diameter of the armature, either the armature reaction or the volts per bar, or both, will exceed the limits given above.

*Paper read before the Institution of Electrical Engineers

Digitized by Google

Putting these two results together we get

$$R > \frac{2{\cdot}4 \times 10^6}{KW. \times l}$$

and taking l as <10in., to be commercial, then

$$R > \frac{240{,}000}{KW.}.$$

From this expression can be drawn up a table of speeds for various kilowatts, beyond which that output cannot be obtained without overstepping one or others of the following limits:

Armature reaction, 1,000 ampere-turns per 1in. diameter.
Average volts per commutator bar, 10.
Reactance voltage of coil under commutation, 5.
Length of armature between end plates, 10in.

The numerical constants chosen are obviously merely arbitrary. Each designer can put in those values which he finds best accord with his own experience, without thereby altering the general conclusions arrived at.

This table would give 240 r.p.m. as the maximum speed for 1,000 kw. With these limitations the diameter for this would be

$$\frac{KW.}{10} = 100\text{in.}$$

The peripheral speed of the armature = 6,300ft. per minute. The machine would be 10in. long, it would have 1,000 ampere-turns per inch and 10 volts per bar, and volts reactance of 5, and would probably stand 25 per cent. overload with fixed lead if the design was in all other respects as perfect as possible.

The weight of copper on the armature, at 1,500 amperes per square inch and 1,000 ampere-turns per inch diameter,

$$= \frac{\text{diameter of armature} \times \text{length of 1 turn}}{47} \text{ lbs.}$$

The resistance of the armature

$$= \frac{D \times T}{10\ A^2} \text{ ohms,}$$

and the R C^2 loss in the armature

$$= \frac{D \times T}{10} \text{ watts,}$$

where T = length of one turn on armature.

So far the number of poles has been in the background, the diameter for a given output and speed being quite independent of the number of poles.

The total magnetic flux of the machine, however, is dependent on the number of poles, and with our assumption of 10 volts per commutator bar, the number of convolutions on the armature

$$= \frac{V \times P}{10}.$$

So that the total flux $= \frac{3 \times 10^{10}}{P \times R}$.

To accommodate this in round magnets at 15,000 lines per square centimetre and a waste field coefficient of 15 per cent., the diameter of magnet core

$$= \frac{45 \times 10^4}{P \times R} \text{ inches.}$$

Suppose we take 550 volts. As we have already taken 10 volts per bar, the number of commutator bars is $55 \times$ poles.

Now in practice what limits the number of poles is (*a*) the least permissible width of a bar, and (*b*) the greatest permissible peripheral speed for a commutator.

Just to fix our ideas let us take 0·2in. as the least *convenient* width for a commutator bar and 3,000ft. per minute as the greatest convenient peripheral speed for a commutator. Diameter of commutator becomes $3{\cdot}5 \times$ poles, and number of poles

$$= \frac{3{,}300}{\text{r.p.m.}}.$$

Taking our 1,000-kw. machine at 240 r.p.m., we find that it could have 14 poles as a maximum, and diameter of commutator would equal 49in.; say 50in.

Also the number of turns on the armature now first appears

$$= 55 \times 14 = 770.$$

The diameter of round magnets would be 11·5in.

Having now settled the diameter of the commutator, the next thing to settle is the length. This is ruled by considerations of heating.

The loss on the commutator results from two causes: (*a*) the contact resistance between the brush and the commutator and (*b*) the friction of the brush on the commutator.

The contact resistance of carbon brushes is in the neighbourhood of 0·03 ohm per square inch, and the coefficient of friction about 0·15. Allowing 2lb. per square inch pressure between the brush and the commutator, the total loss on the commutator for both these causes

$$= A\left(0{\cdot}06 \times \Delta + \frac{d \times R \times 3{\cdot}5}{1{,}000 \times \Delta}\right) \text{watts,}$$

where Δ = density in carbon brush in amperes per square inch.

The product of the current and the first term in the bracket gives the C^2 R loss, and the product of the current and the second term gives the friction loss, both in watts.

Next the density in the carbon brushes should be considered. As this machine is to stand 25 per cent. overload, this should not be more than 35 amperes per square inch.

The expression above then becomes:

$$\text{Total loss} = A\left(2{\cdot}1 + \frac{d \cdot R}{10{,}000}\right) \text{watts.}$$

At our assumed figure of 3,000ft. per minute peripheral speed, this expression becomes:

$$\text{Total loss} = 3{\cdot}24 \times A \text{ watts.}$$

We have now to consider the occult relation between the heat developed and the temperature rise. This can only ultimately be a matter of experience, as it depends entirely on the ventilation. For peripheral speeds of 3,000ft per minute with the armature revolving at 6,000ft. per minute near by, the figure of 15deg. F. rise per watt per square inch of commutator surface may be taken.

Allowing a temperature rise of 70deg. F. gives 4·7 watts per square inch.

And the necessary commutator surface = 3·24 A ÷ 4·7 square inches.

As we know the diameter, the length follows

$$= \frac{0{\cdot}22\ A}{d} \text{ inches.}$$

For our 1,000-kw. 550-volt generator the current = 1,800 amperes, the commutator diameter being 50in., the length is 8in., taking seven 1in. × 1in. brushes per pole.

The magnet winding is the next consideration. For the obtaining of the magnetising force required for the full load total flux, I have no short cut to offer; it must be done on the lines laid down by Dr. John Hopkinson.

The ampere-turns on each magnet pole required to compensate for the demagnetising effect of the armature are, of course, the armature ampere-turns per pole × sine half the angle of the gap (measured in electrical degrees). For a pole arc 75 per cent. of the pole-pitch this works out to

$$= 0{\cdot}383 \times \frac{A \cdot n}{P^2}.$$

If the total magnetising force required per magnet limb is = A T and the length of the mean turn = L inches, then the area for the cross-section of the wire for the shunt winding is given by the following (allowing the winding to reach a temperature of 60deg. C.):

$$\text{Area in mm.}^2 = \frac{A\,T \times L \times P}{V \times 2{,}000}.$$

Allowing 800 amperes per square inch, with the full volts on the shunt windings at a temperature of 60 deg. C., the convolutions per limb

$$= \frac{1{,}600 \times V}{P \times L}.$$

This gives a total length on all limbs of $45 \times V$ yards.

Digitized by Google

Total resistance at 15deg. C.

$$= \frac{1{,}400 \times V^2}{AT \times L \times P} \text{ ohms.}$$

Total weight of copper $= \frac{AT \times L \times P}{2{,}500}$ pounds.

Total magnet loss at 60deg. C.

$$= \frac{AT \times L \times P}{1{,}600} \text{ watts.}$$

The winding space required—*i.e.*, the winding length on the spool × depth of winding (allowing 15 per cent. on the diameter of the wire for insulation, *e.g.*, No. 16 B.W.G., covered to 10 mils, single cotton).

$$\text{Space required} = \frac{AT}{480} \text{ square inches.}$$

Allowing a depth of 3in., winding length of spool

$$= \frac{AT}{1{,}440} \text{ inches.}$$

which = 0·7in. per 1,000 ampere-turns.

The sub-title of this paper would suggest turbo-generators, but the design of these falls under quite a different head from the ordinary "high-speed" steam-driven generator. The results arrived at in the present paper may, however, form a useful starting point for turbo-generator design, for it has been shown that the speed for a given kilowatt output is given by :

$$R = \frac{240{,}000}{KW.} \times \frac{\text{A.T. per 1in. diam.}}{1{,}000} \times \frac{\text{volts per bar}}{10} \times \frac{\text{reactance volts}}{5} \times \frac{10\text{in.}}{\text{length of arma.}} \times \frac{20}{\text{lines per A.T. per 1in.}}$$

Suppose we wish to make a 1,000-kw. generator to run at 1,500 r.p.m.; we know that if we keep the value of the constants at the figure associated with them in the above expression, then the speed can only be 240 r.p.m. If we wish the speed to be higher than this, some or all of the above constants must be sacrificed.

By the use of compensating windings and commutating poles, the armature reaction may be increased to, say, 1,200 ampere-turns per inch diameter; both the volts per commutator bar and the reactance volts will have to be doubled (hence the consumption of copper brushes so often referred to); the length of the armature parallel to the shaft will have to be increased to at least 15in.; the self-induction of the winding on the armature can be reduced to about half, or 10 lines per ampere-turn per inch of conductor, by the use of a smooth-core armature instead of a slotted core.

Summing up now what we have gained, we find the new speed for 1,000 kw.

$$R = \frac{240{,}000}{1{,}000} \times \frac{1{,}200}{1{,}000} \times \frac{20}{10} \times \frac{10}{5} \times \frac{10}{15} \times \frac{20}{10} = 1{,}536 \text{ r.p.m.}$$

so we have 36 r.p.m. in hand.

The diameter of the armature equals

$$\frac{KW. \times 1{,}000}{\text{A.T. per 1in.} \times \text{volts per bar}} = 38\tfrac{1}{2}\text{in.,}$$

making the peripheral speed 15,000ft. per minute.

I think I need not give further examples of how I mean these formulæ to be used; the purely labour-saving ones will commend themselves to those who require their use, and, I think, require no further explanation, but I shall be pleased to further elucidate any of them in the discussion.

ELECTRIC WINDING MACHINES.*

BY PROF. PAUL HABETS, OF BRUSSELS.

(Continued from page 132.)

For the purpose of storing the energy during the stoppages of the winding machinery, M. Ilgner uses a large flywheel mounted on the shaft of a motor-generator, the latter consisting of an asynchronous motor and a continuous-current generator. As the motor-generator is running continuously, the current from the supply station will not vary much. The mean power is also less than in the case of an asychronous motor driving the winding machinery direct. The continuous-current generator, as well as the haulage motor, are excited by a small continuous-current machine driven by an asynchronous motor. This system has been adopted by the Allgemeine Elektricitäts-Gesellschaft at the pits of St. Nicolas, at the collieries of Espérance and Bonne-Fortune, Montegnée, near Liége. The installation, together with the results of some trials, will be described in the following part of this paper. Messrs. Siemens and Schuckert have adopted the Ilgner flywheel system to the machine at pit No. II. Zollern. In this case the motor is a continuous-current machine.

5. *Auxiliary Starting Dynamo.*—In this system the armature of the haulage motor, M (Fig. 9), is connected in series with the armature of an auxiliary dynamo, D *a*, across the mains of a constant-pressure circuit, and a buffer battery can also be inserted; the fields of both machines are connected direct to the mains. The auxiliary dynamo is driven at a constant speed by the steam-engine, G G, working a set of dynamos. The field is regulated by a rheostat, and the E.M.F. generated in the armature opposes the pressure between the mains. When the difference of potential, E″, between the brushes is equal to the pressure between the mains, no difference of potential will be available at the brushes of the haulage motor, M, which will, therefore, be at a standstill. By reducing the resistance,

Auxiliary Starting Dynamo.

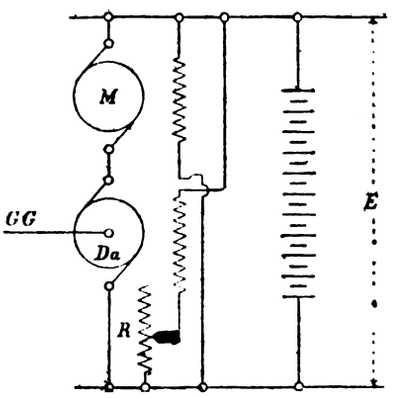

FIG. 9.

R, the difference of potential, E″, between the brushes of M will be E′ = E − E″; a torque will now be exerted by M which will be increased by reducing E″. When the motor, M, has attained its full speed, the counter E.M.F. in the armature of D *a* should be as near zero as possible, and E″ should only be sufficient to overcome the resistance of the armature. The dynamo, D *a*, works therefore as a motor, aiding the steam-engine; but when the resisting moment becomes negative, then the auxiliary dynamo will work as a generator, taking energy from the engine. The current will now flow against the pressure of the mains, and the energy generated by M, which has also become a generator, will increase, and therefore cause M to go slower. In this manner the auxiliary dynamo will keep the speed of M almost constant. The speeds as well as the startings are obtained without other losses than those due to driving the auxiliary dynamo. It is, however, inconvenient to have to regulate the field of the dynamo if this machine cannot be placed near the haulage motor. The auxiliary dynamo may be driven by a motor. The two machines mounted on the same shaft constitute a booster, which may be connected with the mains and the haulage motor in different ways, but can be placed close to the winding machine. This arrangement makes the winding machine more independent of the power station, which may be at a considerable distance from the pit.

6. *Starting Boosters.*—The booster, which we have just described, consists of an auxiliary dynamo with a field rheostat driver by a shunt motor which receives current from the mains. With regard to economy, the booster is

* Paper read before the Institution of Mechanical Engineers (translated from the French).

Digitized by Google

inferior to an auxiliary dynamo driven by an engine, because the efficiency of the booster is less on account of the double transformation of energy. The cost of installation is higher, as the motor and the auxiliary dynamo of the booster must both be of the same power as that of the haulage motor. The speed of the booster may, however, be high, whilst the haulage motor, being direct coupled to the winding machine, cannot have a speed exceeding 50 r.p.m. to 60 r.p.m. By reversing the field current of the auxiliary dynamo, the booster will work as a booster proper—*i e*, will raise the voltage of the mains. We might, therefore, arrange matters so that the pressure of the circuit will be doubled when the haulage motor is running at full speed. Under these conditions the power of each of the booster machines need not be more than half of that of the haulage motor, thus making the booster less costly. For this purpose the voltage of the haulage motor must be twice that of the mains, and we must, therefore, either reduce the pressure of the distributing system or design a high-tension motor, which with continuous-current machines is difficult when the tension exceeds 500 volts. The problem may also be solved by driving the winding machine by two motors connected in series, each of which will, therefore, only receive half of the total voltage. The latter system, which was brought forward by the Union Elektricitäts-Gesellschaft, has been adopted by Messrs. Schuckert and Co. in the case of the winding machine at the Friederich-Franz mine at Lübtheen (Mecklenburg). Fig. 10 is a diagram of connections. An Ilgner flywheel may be mounted on the booster shaft. This solution has been applied by W. Lahmeyer and Co. to the winding machine of the Tremonde pit of the Mining Company of Liguy-les-Aira. For the purpose of bringing the flywheel into proper play, a second booster is connected in series with the armature of the starting booster in such a manner as to vary the speed of the latter automatically, and also inversely as the strength of the armature current of the haulage motor. M. Creplet reduces this group to a single dynamo, the shaft of which carries a special flywheel. As it is possible to allow a great variation of speed for this dynamo, the flywheel can be much reduced. A machine on this system has been installed by the Compagnie Internationale d'Electricité de Liége for the Fléron pit of the Hasard Collieries at Micherot, near Liège. Very few trials on electrically-driven winding machines have been published up to the present time; the trials made on the machine at pit No. II. Preussen afford the only account we possess of the working of a machine driven by a three-phase motor. We have made a great number of trials on the machine installed at St. Nicolas, at the collieries of Espérance and Bonne-Fortune, Montegnée, and will now give a detailed description of this installation, together with the results we have obtained.

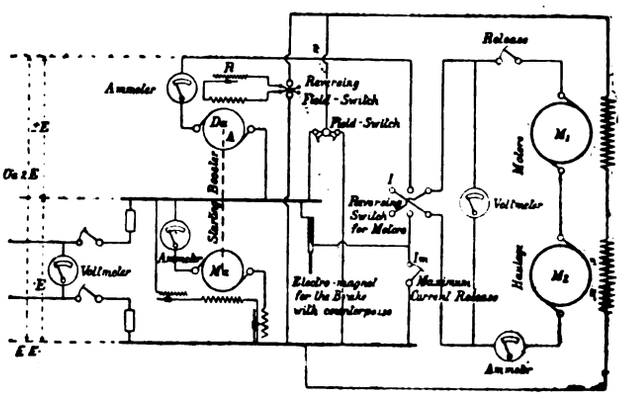

FIG. 10.

IV. *Electrically driven Winding Machines at the Pit of St. Nicolas at the Collieries of Espérance and Bonne Fortune, Montegnée*

1. *Description of the Installation* (Fig. 11).—The machine was supplied by the Société Belge d'Électricité A.E.G. It is designed to draw 500 tonnes (492 tons) from a depth of 800m. (2,625ft.) in eight hours. The loads are four tubs holding 535 kg. (1,102·3lb.) of coal or 750 kg. (1,653·4lb.) of stone; each tub weighs 250 kg. (551·1lb.), and the cage weighs 1,800 kg. (1¾ tons). The electric energy is supplied from the power station, which was constructed in 1899, at the pit of Espérance, and which contains three sets of three-phase generators working at 1,000 volts and with a frequency of 44; the output of each machine is 200 kw. Two of the sets also supply current for pumping, ventilation, picking, etc., at the pits of Espérance and St. Nicolas; the third is a reserve set. The coal is drawn from four underground landing stages at depths of 368m. (1,207ft.), 342m. (1,122ft.), 288m. (945ft.), and 185m. (607ft. On account of the nature of the deposition of the beds and the extent of the field of exploitation, it may eventually be necessary to draw simultaneously from several seams, which will require one or two stoppages

(See also Fig. 12, page 35.)

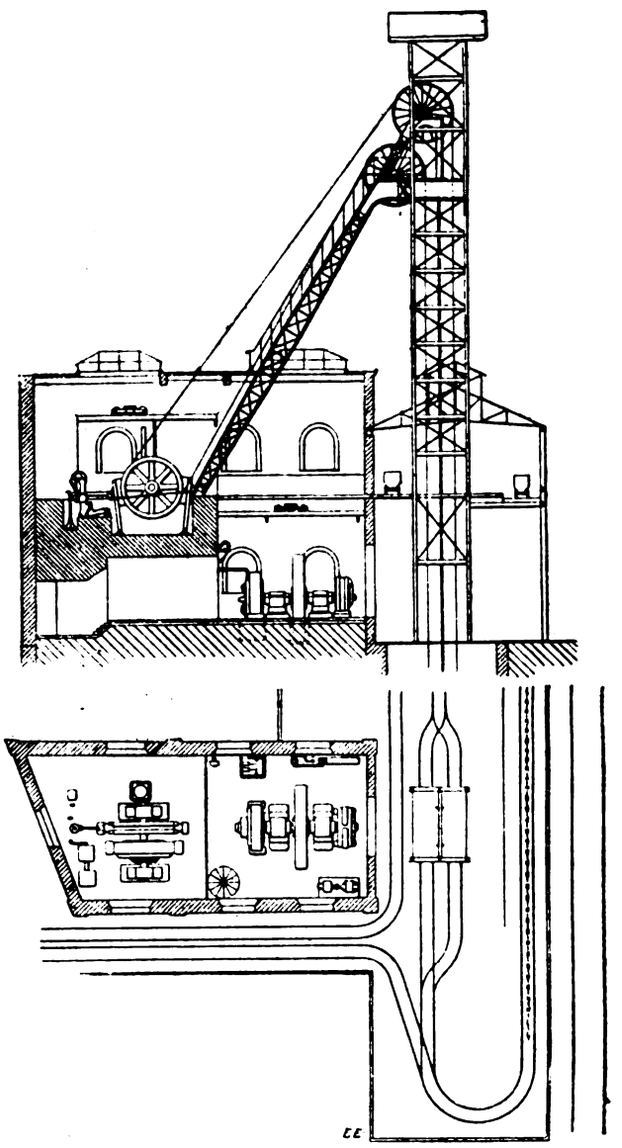

FIG. 11.

during each lift. The time spent in unloading the cage at the bank of the pit, and simultaneously loading the cage at the bottom landing place, is 30 seconds, and loading the cage at intermediate landing stages takes 20 seconds. Under these conditions the maximum haulage speed need not exceed 12m. (39ft. 4¼in.) in order to draw a total of 500 tonnes (492 tons) from a depth of 800m. (2,625ft.). When the depth is less or the tonnage is smaller, the speed may be slower. Local circumstances have led to the adoption of a Koepe pulley with a central groove for a flat-wire rope, and two brake rims, one on each side of the groove. The motor and the Koepe pulley are mounted on the same shaft; the diameter of the pulley is 3m. (9ft. 10⅛in.), and requires, therefore, only a medium size motor. The haulage speed is 10m. (32ft. 9¾in.) when the motor makes 64 r.p.m. Notwithstanding the high

Digitized by Google

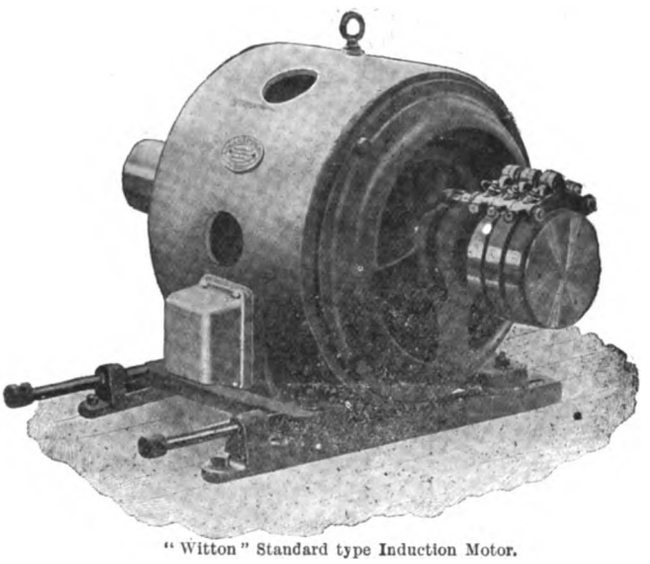
frequency, a three-phase motor might have been designed for this slow speed. Preference has, however, been given to a continuous-current motor; and a motor-generator of the Ilgner type, consisting of a three-phase motor and a continuous-current generator, has been adopted for the following reasons. During the period of acceleration the three-phase motor would have absorbed 615 h.p., a power which the central station would not have been able to supply with the present plant. Besides, a three-phase motor with a starting rheostat is very wasteful, and the loss of power in this case would have been still higher on account of the intermediate stoppages. Notwithstanding the conversion of the three-phase current, the motor-generator is in this case more economical, as it almost entirely prevents any losses during acceleration, and the slow speed, which must be adopted when the haulage is reduced, and also during the night shift. A motor-generator with an Ilgner flywheel will also equalise the demand on the power station, no matter how the load varies. The power station will then be able to supply the other motors if the pumping is done during the night.

(To be continued.)

TRADE NOTICES AND NOVELTIES.

"Witton" Single and Polyphase Motors.

The General Electric Company, Limited, Queen Victoria-street, E.C., have issued a new catalogue of their single and polyphase induction motors, which includes a full specification and a mass of useful data. Accompanying is an illustration of



"Witton" Standard type Induction Motor.

the company's standard-type induction motor on slide rails. It is well known that they have of late made rapid strides with their single and polyphase machinery. There is absolutely no need to go to the Continent for such plant now. That is proved, if proof be required, by the many important contracts entrusted to the company, amongst which reference may be made here to orders from South London, Hastings, and Reigate for single-phase and from Dublin and Cardiff for three-phase plant.

Motorcar Troubles.

The subject of the troubles which motorists have experienced in the past with electric wires on motorcars is dealt with on a card, which includes lighting-up tables, published by Messrs. W. T. Glover and Co., Limited, Trafford Park, Manchester. Those who have had to do with internal-combustion engines, arranged for electric ignition, are well aware of the troubles and expense that arise from the insulation of the leads breaking down, but few persons, we are told, know what causes the same. Messrs. Glover having had their attention drawn to the matter, discovered that the causes are two-fold. The static discharge set up between the conductor and the outside sheathing of the cable is partly to blame, and the destruction of the rubber insulation by vagrant oil is the other cause. As a preventive they now recommend their specially-designed, oil-proof, and static discharge proof cables. The oil-proofing is achieved by covering the insulation with a closely-woven fabric sheath, which is impregnated with an oil-resisting compound. The further feature is the metallic sheathing, which prevents chance of shock and deterioration of the cable by the static discharge induced by the high potentials used for electric ignition. This sheathing is arranged for connecting to the metal work of the car or engine itself, which is at earth potential. Messrs. Glover will be pleased to forward one of these cards to any reader who may apply.

Electric Lighting Accessories.

Messrs. J. H. Tucker and Co., of Sampson-road North, Birmingham, and London, have just issued a new catalogue of the electric lighting accessories which they manufacture. Tumbler switches are listed in great variety, including a special pattern with locking ring to prevent the removal of covers by unauthorised persons. This switch should certainly prove useful for asylums, schools, and public buildings. Fig. 1

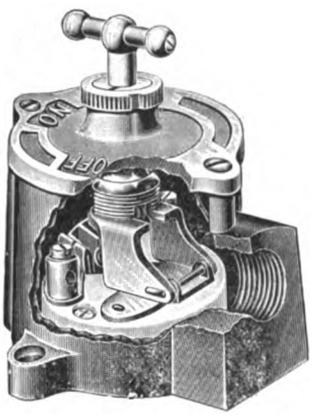


Fig. 1.

herewith illustrates a pattern introduced by the firm to meet the demand for their patent tumbler switch enclosed in a cast-iron case. The handle is in the centre of the cover, and has a "turn" action, being connected in such a manner that the movement is very easy. The "on" and "off" positions are indicated upon the cover. The spindle carrying the handle works through a stuffing box and gland. An indiarubber ring is placed between the cover and box to ensure a watertight joint. Both handle and cover are nickel-plated. Considerable space is also given to wall sockets. The iron-cased two-pin type (Fig. 2) consists of a china interior fitted into a cast-iron box.

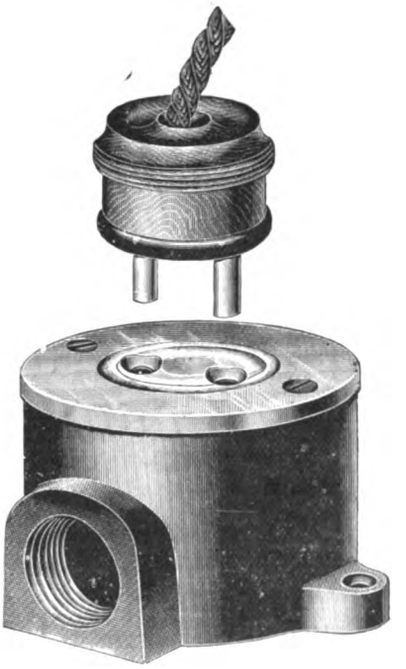

Fig. 2.

The metal parts carrying current are sunk in the china, and the poles are well separated by a wall of china. We notice that a watertight pattern of wall socket, very similar in general construction to the above, is also supplied by the firm. Among the further contents of the catalogue are some well-designed distributing switch and fuse boards, ceiling roses, counterweight sets, cut-outs, lamp-holders, switches of various useful types, and main switchboards.

Aron Meters.—"Notes on Meters and Useful Data" is the title of a little pamphlet just issued by Aron Electricity Meter, Limited, 114, Union-street, Borough, S.E., and we find it faithfully describes the contents, which should be valuable for reference purposes.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

Post Free, Payable in Advance.)

Bound Volumes of "THE ELECTRICAL ENGINEER," containing half-year's copies, bound in Dark-Blue Cloth, Gold-Lettered, price 8s. 6d. New Volume, January to June, 1905, now ready.

THE TELEPHONE COMMITTEE.

The report of this committee has been issued, though the minutes of evidence are not yet ready. However, the former is the important part, the latter merely assisting to decide how far the former is logical and justified. The committee was appointed to consider the agreement between the Postmaster-General and the National Telephone Company, whether it should become binding or be modified, and whether the interests of the employés of the company had been duly considered. The telephonic policy of the various Governments of this country since telephony has been proved practical has been of such a character as not to be understanded of the multitude unless it be summed up in the phrase, "Don't bother; let things slide, and see what turns up." That state of things continued until the matter became acute, and then came an agreement about trunk lines. Subsequently came the London agreement and municipal licenses. Finally, the agreement upon which the report is made. The history of telephony can be written in ten lines. First, doubt as to practicality, Government afraid to risk a few pounds on experiment, private enterprise proves the matter, and the National gradually gets a monopoly; agitation for Government to take what was legally certified to be telegraphic, and hence, under the Telegraphic Acts; finally, get rid of the enterprising company, which has done most of the pioneer work, at the least possible cost, thus the agreement under consideration. In the opinion of every one who is not biassed the Government throughout has acted in the most contemptible manner, and any private individual so acting would long since have been given the coldest possible shoulder in business circles. The final agreement was made under the ægis of expediency—something that will go down with the electorate. The Government always held the whip-hand because of the legal decision; and, much as we dislike the methods of the National, they have been infinitely superior to those of the Government. The agreement ought never to have been required. There ought never to have been a company with a practical monopoly, which has in equity to be bought out at the nation's expense, and which deserves all that it can in a legitimate manner demand. The text of the committee's report is given elsewhere in full, and, as will be seen, is not a very robust document, dealing more with a summation of details than anything, merely giving a qualified general assent to the agreement and suggesting certain modifications which, if adopted, will leave things pretty much as they are. Clause 27 is the important one. It reads: "On a careful review of the bearing of the agreement as a whole upon the interest of the public, we find that the policy of purchase is to be preferred to the other alternatives; and that if safeguarded as we recommend in paragraph 28, it will leave the position of the municipalities unprejudiced as regards the period succeeding the cesser of the company's rights in 1911. We are of opinion that in order to make it clear that municipal licenses can be granted between Aug. 31, 1905, and Dec. 31, 1911, without giving the National Telephone Company rights to compensation under the Telegraph Act of 1899 in respect of licenses granted after Aug. 31, 1905, it is desirable that the agreement should be modified by omitting on p. 6, paragraph 2 (1) *b*, line 6, the word 'whether' and the words 'or after.' After allowing due weight to the criticisms that have been passed upon details, we think that the agreement provides on balance the best security available in the circumstances that the property purchased shall be good and suitable in quality, and that no more than a reasonable price shall be paid." The succeeding clause recommends the "House of Commons

Digitized by Google

should not disaprove of the agreement," but should accept it and the modification suggested. So far as we can judge, therefore, municipal enterprise, be it good, bad, or indifferent, has received a set back, for we cannot believe that any municipality will proceed to trouble and expenditure with the indefinite prospect of in 1912, or some not far-off year, having to consider, agree, or arbitrate as to the then value of their property for sale, or of terms under which they shall be allowed to continue operations. The whole matter, if justness and honour are to reign supreme, is very simple. So far as it concerns the National Company the two parties are agreed—let the agreement stand. So far as the municipalities are concerned the question is not quite so simple, as it depends upon the determination of the Government to work all exchanges or to permit under certain conditions of local control over local areas. When this matter is decided, the really just solution of the problem is, as we say, simple. The report deals satisfactorily with the question of the company's employés.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

PUBLIC LIGHTING.

The following letter has been addressed to the town clerk of the city of London, Guildhall, E.C., by the City of London Electric Lighting Company, Limited:

Sir,—The position which has arisen by reason of your letter of the 17th ult., in which you state that the Streets Committee have been authorised to revert to the use of gas for certain of the main thoroughfares of the city, and requesting my company to remove its electric lamps by Sept. 29 next, has been carefully considered by my Board, and I am now directed to write you in reply as follows:

Many members of the Court of Common Council may be unaware of, or may have forgotten, the circumstances under which the three contracts for the electric lighting of the eastern, central, and western districts of the city were entered into, and I therefore shortly recapitulate them. Specifications were prepared by the Corporation, and tenders were asked for in accordance therewith. The tenders of the Laing, Wharton, and Down Syndicate for the eastern district and of the Brush Electrical Engineering Company for the central and western districts respectively were accepted, and were embodied in three contracts.

Under these contracts the contractors were placed under obligations to make a large expenditure on plant, mains, lamps, etc., for the public lighting within a certain time and to supply the public lamps with energy at a very low rate in consideration of certain advantages as regards private lighting given to the contractors, which advantages, as events have happened, have proved to be illusory. The contracts were subject to provisional orders (or Acts of Parliament) being obtained by the contractors, and the Corporation stipulated that the contracts should be embodied in the provisional orders. These latter were granted, but the Board of Trade would only allow certain of the terms of the contracts, which imposed obligations on the contractors, to be inserted in the orders, including the obligation to sell that part of the undertaking relating to public lighting to the Corporation upon more favourable terms than were made applicable to the remainder of the undertaking. These three contracts and provisional orders were in due course transferred to my company with the consent of the Corporation.

My company had nothing to do with the negotiation of the contracts and provisional orders, but simply took them over with all their obligations, including those relating to the public lighting. This transfer took place in 1891, and it was not until about 1899, after my company had expended £119,520 in respect of the public lighting, that the question of the validity of the contracts was raised by the Corporation. At Dec. 31 last this expenditure stood in my company's capital account at £128,997.

This question of the validity of the three contracts was carried through the various courts of law, and a final decision was given by the House of Lord, with regret, that the central and western contracts were invalid *ab initio* on the technical ground that certain members of the Corporation had a small share interest in the Brush Company—the original contractors. In giving judgment, the Lord Chancellor stated: "The defendants—*i.e.*, the Corporation—have repudiated them—not, as I understand, that they have any objection to the substance of the contracts, but, being advised by counsel that the contracts were invalid, they felt bound to test that question in a court of law. . . . I have striven to escape the stringency of the language, since I think that no one will doubt that the contracts were fairly and properly made with a due regard to the public interest, but I cannot escape from the language of the statute." Thus, my company's shareholders had to suffer for something which my company had no hand in, as it merely, as above stated, took a transfer of the contracts with the consent of the Corporation. The contract for the eastern district was declared by the House of Lords to be valid and subsisting.

Since the decision of the House of Lords my company has, at the request of the Corporation, carried on the public lighting until the present time, as though all the contracts were still valid. On March 25, 1905, my company received a letter from you inquiring upon what terms my company would be willing to enter into a contract for lighting the main streets with improved lamps, etc. My company replied asking for particulars of the improvements which were required, and on April 27, 1905, you replied that a specification was being prepared by the electrical engineer to the Corporation, of which a copy would be sent to my company in due course. The specification has not been received, but on May 4, 1905, the Street Committee submitted a scheme for replacing 47 electric arc lamps by gas lamps, of which eight arc lamps are in the eastern district. My company had no official cognisance of this scheme until June 19, when a letter was received requesting my company to remove its electric lamps from Fleet-street, Queen Victoria-street, Monument-street, and part of Lower Thames-street by Sept. 29 next.

To comply with this request would mean the destruction of part of the capital outlay imposed upon my company by the contracts and provisional orders, and a corresponding loss of revenue of about £1,222 per annum. My Board consequently felt that it was a matter which required their most careful consideration, especially as after being requested to tender for improved public lamps, nothing further has been done, and in the meantime gas lighting has been adopted to a serious extent. In this connection I am to remind the members of the Corporation that my company did not have a free hand in the selection of either the standards, the lanterns or the glass of the present electric arc lamps, all of which were settled by the late Colonel Haywood, the then engineer to the Commissioners of Sewers, and to point out that it is not fair to compare electrical apparatus which was the best of its kind in 1891 with modern gas apparatus.

My Board would have been only too pleased to co-operate with the Corporation in improving the lighting of the streets. In all probability my company would have been able to submit such terms as would have shown at least as great a saving as the alleged saving mentioned in the Street Committee's report of May 4, 1905, and the improved electric lamps would have afforded better illumination than any form of gas lighting. But, as stated above, my company had no opportunity of tendering, and have never received the specification promised by your letter of April 27 last.

My Board have been precluded from incurring on their own initiative any further large expenditure on the public lighting owing to the uncertainty of the position of my company as regards the public lighting. It would manifestly have been impolitic for my company to do so without the security of a fresh contract, especially in view of Mr. D. J. Ross's statement in his letter of Oct. 19, 1904, to my company "that the Corporation does not recognise the existence of any contract for the eastern district of the City."

My Board cannot agree with this view, as they are advised that there can be no question after the decision of

Digitized by Google

the House of Lords that the eastern contract is still binding on the Corporation and my company. As regards the central and western contracts, apart from the legal position, my Board submit that in equity my company has a just claim upon the Corporation that it should not destroy to the considerable extent involved the capital expenditure made by my company in pursuance of the obligations imposed upon it by the Corporation.

My Board are anxious that the present amicable relations between my company and the Corporation should not be disturbed, and I am therefore directed to suggest that a special committee should be deputed by the Corporation to confer in a friendly manner with my Board with a view to the public lighting of the streets by my company being settled in a manner satisfactory to both parties.

I am to request that you will be good enough to place this letter before the Court of Common Council at its next meeting. I am to add that I am forwarding a copy of this letter to each member of the Corporation.—I am, Sir, your obedient servant,

(Signed) J. CECIL BULL, Manager and Secretary.
The City of London Electric Lighting Co., Limited.

THE PHOTOMETRY OF UNSYMMETRICAL SOURCES OF LIGHT.*

Considerable labour and time has always been involved in photometric determinations on such sources of light as the electric arc lamp because of the want of symmetry in the light radiations. Even the ordinary vertical carbon arc necessitates the determination of a complete light radiation

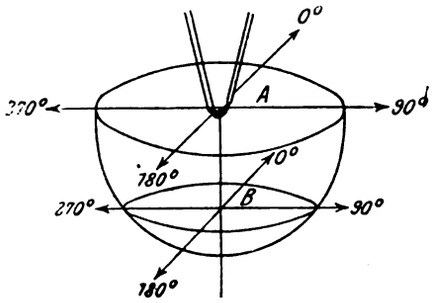

FIG. 1.

curve over a whole vertical plane, whilst the newer flame arc lamps, in which the carbons are inclined to one another and throw the arc downwards, are unsymmetrical not only in the vertical plane, but also in the horizontal plane, so that unless a lumen-meter (Blondel) or a globe photometer (Ullbrich), or some similar more or less complicated apparatus is employed, it would appear necessary to take a large number of readings in various vertical planes and in various horizontal planes. The writer of the present article, however, points out how this labour can be kept within reasonable limits whilst giving quite sufficiently accurate results even with the most unsymmetrical sources.

The method involves (1) the taking of a light radiation curve in any one vertical plane, either over 90deg. or over 180deg., according to the nature of the lamp; (2) the taking of a few readings in two horizontal planes—*e.g.*, in the plane of the arc (A, Fig. 1) and in a plane at, say, 45deg below the arc (B, Fig. 1). Usually four readings for each of these horizontal plane curves are sufficient.

From (1) the mean spherical or hemispherical candle-power for the one particular vertical plane is obtained in the ordinary way.† From (2) the ratio of the average candle-power to the candle-power at the particular vertical plane used in (1) is obtained for each of the two horizontal planes. This ratio will be found to be practically the same for both planes. In order to obtain the real spherical or hemispherical candle-power of the lamp, it is then only necessary to multiply the mean spherical or hemispherical candle-power for the one vertical plane obtained from (1) by the average value of the ratio obtained from (2).

The simplicity of the method is best shown by an example. Fig. 2 shows the polar candle-power curves taken with and without globe on an arc lamp of the inclined-carbon type. The carbons were ordinary (not flame) ones, and were of unequal size (10mm. and 7mm. diameter respectively), so that one was always somewhat longer than the other. This led to an unusually unsymmetrical light distribution The curves in Fig. 2

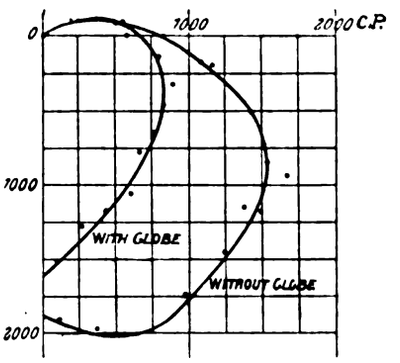

FIG. 2.

were taken for the vertical plane normal to the plane of the carbons. The mean hemispherical candle-powers for this plane calculated from these curves are 1,620 without globe and 980 with opal glass globe. The light distribution in the two horizontal planes, A and B (Fig. 1), was next measured, and is shown in the polar curves in Fig. 3. In order to arrive at the average light intensity represented by these curves, it is not necessary to convert to rectangular co-ordinates, as the average of 16 (or even 4) equidistant radial vectors leads to the same result practically. The vertical plane for which the curves in Fig 2 were obtained

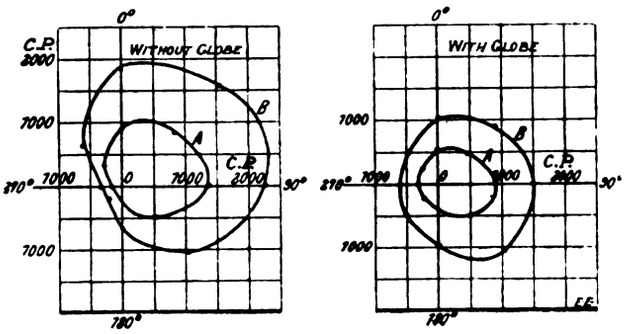

FIG. 3.

is the one marked 0° in Fig. 3. The following table gives the results obtained from Fig. 3:

	Without globe		With globe	
	Curve A.	Curve B.	Curve A.	Curve B.
L_M = Mean candle-power in horizontal plane ... Average of 16 radii	640	1,260	520	1,030
L_M = Mean candle-power in horizontal plane ... Average of 4 radii...	660	1,300	525	1,040
L_0 = Candle-power on plane marked 0° (Fig. 3)	900	1,860	530	1,050
Ratio $\frac{L_M}{L_0}$	·71	·68	·98	·98

Since the ratio is practically the same for the two horizontal planes tested, it will be safe to assume that it is the same for all other horizontal planes. The real hemispherical candle-power of the lamp is, therefore, obtained by multiplying the hemispherical candle-power obtained from Fig. 2 for the one vertical plane by the average ratio obtained from Fig. 3, or real hemispherical candle-power without globe = 1,620 × ·695 = 1,130; real hemispherical candle-power with globe = 980 × ·90 = 960. The results obtained of this method cannot, of course, claim extreme accuracy, but the accuracy is ample for such a fluctuating source of light as an arc lamp.

* Abstract of an article by Dr. L. Bloch in the *Elektrotechnische Zeitschrift*, July 13, 1905.

† It is not even necessary to project the polar curve on to a circle and find the mean ordinate of the resultant curve by planimeter, as quite sufficient accuracy is attained by taking the arithmetical average of, say, 10 equidistant points on the resultant curve,

THE ADMINISTRATIVE COUNTY OF LONDON AND DISTRICT ELECTRIC POWER BILL.

(*Continued from page 129.*)

Amongst the witnesses heard last week was Colonel R. E. CROMPTON, who said that he did not regard the Tyneside scheme as any indication of success in London. The advantages of Tyneside were absent from London. The estimate of the cost of distribution put forward by Mr. Merz was ridiculously low, and he could find no justification for it. The total length of street mains was given as 363 miles, and the proposal was to distribute through these 120,000 kw. The cost of mains was put down at £1,089,000, and that worked out at £9 per kilowatt—to him a surprising result, seeing that in London undertakings the cost had varied from £54 in Stepney to £25. 12s. in Poplar. The estimate of £9 would have to be trebled probably. He was certain Mr. Merz had made some mistake, and that there was an under-estimate to the amount of possibly £2,000,000. There was an over-estimate of the amount of power likely to be required in London, and the number of hours' use estimated was beyond the average. The average hours of labour were shorter in London. With the estimated generation cost he had no quarrel. He did not consider the scheme was justified by any demand from existing undertakers or from railway companies, who could generate for themselves more cheaply. For instance, if the Great Eastern Railway electrified their suburban lines and needed 35,000,000 units per annum, with a 45 per cent. power factor, they would have to pay the promoters £76,000 a year. They could generate the electricity themselves for £32,500, leaving £43,700 a year to write off the sum the plant would cost. There was no necessity for such a scheme in London; it was not sound, and the proposal to supply such a large area from practically one centre was wrong from every point of view. In course of cross-examination tenders were put in to show that certain cable companies were prepared to carry out Mr. Merz's scheme for feeders and distributors at the prices given in the estimates.

When the committee met on Monday Mr. Fitzgerald was able to announce the withdrawal of several more opponents to the Bill. Thus the Corporation of Bromley and the Beckenham Urban District Council have agreed to clauses giving them an option for 12 months to take a bulk supply from the company on terms to be fixed by arbitration, and to be more advantageous to them than generating their own supply. The agreed clauses with the London Electric Supply Corporation and the South Metropolitan Electric Light and Power Company provide that these companies should adopt the Administrative Company's maximum price for power supply as their maximum price, any reduction in the charge for bulk supply given by the Administrative Company to go to the benefit of the consumer. The terms on which the bulk supply is to be furnished is to be determined, failing agreement, by arbitration within a year of the passing of the Act, and the terms are to be such as should make it substantially more advantageous for the companies to take a supply than to extend their works and generate the additional requirements for themselves. The South London Electric Supply Corporation have agreed to a similar clause. The agreement with the Charing Cross and West-end Company follows the same lines as that with the County of London Electric Supply Company. The Chelsea, the St. James's and Pall Mall, the Kensington and Knightsbridge, the Notting Hill, and the Westminster Companies have agreed to withdraw their opposition owing to certain clauses being altered. One of these alterations restricts the company from supplying in the non-industrial area to any but authorised distributors and railway companies.

Mr. MACKINNON WOOD gave evidence on behalf of the London County Council. He said he did not believe in the cheap prices scheduled, because past experience in other matters, such as water supply, had shown such promises to be illusory. The Bill would create a monopoly, both in the generation and distribution of electricity. At present the municipalities had the right to the future profits of electricity works, but with this monopoly in existence when the time for purchase arrived the borough councils would only have the cables to take over. He doubted whether manufacturers could demand as a right a supply of electricity at the prices scheduled. The whole scheme was to force existing companies and local authorities to take the bulk supply on the threat of competition. In his opinion the purchase clause proposed by the promoters was altogether worthless. The basis of purchase—payment of capital expenditure—was totally wrong, especially in the case of a company which could buy up other companies. The promoters could claim to be repaid large sums of capital spent on obsolete plant.

Cross-examined, witness said it was true that the London County Council jurisdiction extended over only a quarter of the area for which the promoters asked, and that the Kent, Surrey, and Essex County Councils, who represented 77 per cent. of the area, did not oppose the Bill.

On Tuesday, Mr. HAWARD, controller of the London County Council, laid stress on the difficulties which the auditor to be appointed under the purchase clauses of the Bill would meet with.

Mr. COWARD, K.C., addressed the committee on behalf of the County Council, contending that it would be a huge mistake to create a vast monopoly.

Mr. SPENCER HAWES gave evidence as to the Hackney supply system. The works' cost last year had averaged 0·88d. per unit sold. The output had been over 2½ million units, of which 554,000 units went to power consumers and 640,000 units to public lighting. Including capital charges on the station, the units cost 1·17d. Management and distribution expenses, including capital charges on mains, were 1·09d. per unit. They had now adopted the tariff given in the Bill for supplying the power consumers. The demand was growing, and there were three methods in which the Borough Council could deal with the situation created by this demand. It could (1) extend its own works so as to be able to deal with the entire output; (2) use the present plant to its full capacity, and take from the power company the additional energy required; (3) scrap the entire municipal undertaking, and take a complete bulk supply from the company at the terms quoted above. On an assumed output of 11,130,000 units per year, with a load factor of 20 per cent. and a maximum load of 6,370 kw., Mr. Hawes calculated the financial results of the three alternatives would be as follows:

	Annual working expenses and capital charges.	Per unit sold.
(1)	£51,450	1·109d.
(2)	59,240	1·277d.
(3)	65,540	1·413d.

This showed it would be best for the Corporation to generate its own supply. He assumed that the company's terms for bulk supply would be those agreed with the Stepney Council, and did not think that agreement an advantageous one.

Cross-examined, he said that although the Hackney Council would be able to supply as cheaply as the company, he thought the company would offer special terms to some large consumers to induce the Board of Trade to let them supply in the Hackney area.

On Wednesday last, at the opening of the proceedings, Mr. FITZGERALD said he was informed by the parliamentary agents that unless the committee stage of the Bill was finished by Thursday evening there would be considerable danger of the Bill being lost simply by effluxion of time. Under those circumstances he had to make an appeal which he had never made before, and that was to ask the committee to sit late that day and the next to enable the committee stage to be finished and a decision given on Thursday evening. Having regard to the time spent in Parliament and the great expenditure incurred by the parties, it would be a great misfortune if the Bill were lost by effluxion of time.

This was agreed to by the chairman.

It was then announced that the South London Electric Supply Corporation had withdrawn opposition, as an agreement had been come to with the promoters. A map was then put in to show that in one half of the area sought by the promoters there was either no opposition at all to the Bill or no opposition from persons supplying electricity.

Digitized by Google

The case for West Ham was then taken, the witness for the Corporation being Mr. W. J. W. BULLOCK. He said that the coal they used cost 7s. 10½d. per ton, and was delivered into the bunkers for less than 8s. 6d. per ton. The total cost per unit sold was 1·133 last year. He considered the West Ham station was quite as well situated as the proposed works of the company as regards cheap coal and abundant condensing water. He did not think it would be advantageous to take a bulk supply until the present works had been extended to contain 18,000 kw.

Mr. ALBERT GAY was then examined as to the Islington system, which last year sold 406,369 units for power purposes. It would not pay to take a bulk supply at the schedule rates of the company. He was cross-examined at some length on this point.

It was announced that the City of London Electric Lighting Company had withdrawn their opposition.

Mr. A. H. SHAW gave evidence as to the Ilford undertaking, and Mr. J. W. BENTON, the clerk to the Council, was also heard. The opposition on behalf of Battersea was also heard before the committee adjourned.

On Thursday the agreements made with the South London Company and the City of London Electric Lighting Company were put in.

The case for the city of Westminster was then heard. The chief points made by the witnesses were that the purchasing power of the Corporation under the Electric Lighting Acts would be rendered less valuable, and that the breaking-up of the streets should not be allowed. It was shown that the Corporation had by a Bill this year obtained powers to purchase with the works of the Westminster Company the station of the Central Electric Company. The witnesses also objected to the promoters supplying railways in the Westminster area.

Mr. FITZGERALD, K.C., announced that the Gravesend Corporation and the Richmond Electric Light and Power Company had withdrawn their opposition.

Dr. HUGH MANSFIELD ROBINSON, town clerk, Shoreditch, stated, in examination by Mr. Courthope Munroe, that the combination of electricity works and dust destructor and the utilisation of the exhaust steam for heating the baths had resulted in an economy of between £3,000 and £4,000. The Council had as customers the consumers of over 50 per cent. of the power used in the district. A large proportion of the remaining power was used by two large firms who generated for themselves, and were unlikely to change. There had been no lack of "push" in the matter of extending the use of power. He admitted having made a proposition at a meeting of municipal authorities that there should be a scheme of municipal supply in bulk. He agreed that the promoters could in this respect do practically what the London County Council would be able to do. He objected, however, to the provisions of the Bill respecting capital charges.

Mr. C. NEWTON RUSSELL, Shoreditch Borough Council, stated that the highest load factor of any power consumer in the district was 22 per cent.; the average was 15 per cent. He calculated that in four years' time, by utilising the land already acquired, the Council would be able to generate at £6·2 per kilowatt against £8·4 estimated by promoters.

Cross-examined by Mr. Lloyd: He had no objection to buying in the cheapest market, but in a few years the Borough Council would be able to generate quite as cheaply for themselves as the company would do. Witness stated that his Council had given a quotation to the prospective North-East London Railway for supply of energy, but for lighting only. He agreed that in order to supply the suburban lines of the Great Eastern Company, if they were electrified, would need something like a tenfold enlargement of the Council's plant. During the Council's last financial year a third of the energy generated was used for power.

Mr. C. H. WORDINGHAM stated that he had inspected the extension of the Shoreditch Borough Council's works. It was of quite an up-to-date character, and similar in type to that proposed by the promoters.

COUNSEL for Dartford Urban District Council opposed the Bill on the principle of monopoly, besides which a few years might see a substantial alteration in prices of electrical supply all round.

COUNSEL for Southwark Borough Council, after explaining the history of the Council's electrical undertaking, made the objection that all the promoters' tributary mains were to be laid on the solid system, necessitating the breaking up of streets for extensions. The Council also objected to the Board of Trade acting in a judicial character, and to companies having power to transfer their undertakings without consent of the local authority. It was a fallacy to suppose that small power users would obtain a supply at ¾d. per unit. This was the "standard" price, but as a large quantity of energy would be supplied to big concerns for traction and the like purposes at little more than ½d. per unit, the small consumer would have to pay nearly 1½d.

Mr. COURTHOPE MUNROE, stating the case for the Bermondsey, Leyton, and Lewisham authorities, contended that the provision in the promoters' Bill, that they should not supply a customer with energy for lighting beyond 20 per cent. of the total power supplied, was illusory, because this proportion was ample to supply current for lighting, even if the consumer had to go to the trouble of having a motor of nominal size installed for power.

At 5.45 the CHAIRMAN announced that the case would be resumed at 11 o'clock to-day, when it is understood an attempt will be made to reach a decision, at any rate on the preamble. The evidence, however, has not yet been finally disposed of, as a witness is to be called on behalf of the City of London Electric Lighting Company.

BRIGHTON ELECTRICITY ACCOUNTS.

The accounts of the Brighton Corporation electricity department for the year ended March 31, 1905, show a total expenditure on capital account to that date of £595,039. Abstracts of the revenue account, balance-sheet, and statement of electricity generated, sold, etc., are appended.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
To generation of electricity	34,795	3	5
Distribution of electricity	4,192	14	8

WOLVERHAMPTON ELECTRICITY ACCOUNTS.

From the accounts of the Wolverhampton Corporation electricity department for the year ended March 30, 1905, it appears that the total expenditure on capital account to that date amounts to £163,875. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are appended.

APPOINTMENTS VACANT.

Chief Instructor in Mathematics, Northampton Institute, Clerkenwell. Salary, £150 per session. Applications by 30th inst. See advertisement.

Premium Pupil, Kilmalcolm Electric Lighting Co. See advertisement.

Assistant Engineer about 25 years of age, with good knowledge of mechanical engineering. Applications to G M 532, Messrs. Deacon's, Leadenhall-street, London, E.C.

Practical Engineer to supervise the equipment of a complete electrical tramway in India. Applications to Box No. K 10, *Electrical Engineer* Office. See advertisement.

Mechanical and Electrical Engineer. Salary, 30s. per week. Applications to R. N., *Electrical Engineer* Office.

Junior Assistant Electrical Engineer, Burnley electricity works. Salary, £119. 12s. per annum. See advertisement in last issue.

Pupil, Stretford Urban District Council electricity department. See advertisement in last issue.

Chief Draughtsman, also Assistant Draughtsman. Applications to T. K., care of Davies and Co., advertising agents, Finch-lane, Cornhill. See advertisement in last issue.

POST OFFICE TELEPHONE AGREEMENT, 1905.

The following is the full report of the Select Committee appointed to consider the agreement of Feb. 2, 1905, between the Postmaster-General and the National Telephone Company, and to report as to any recommendations thereon whether it is desirable in the public interest that the agreement should become binding, with or without modifications, and also whether the interests of the employés of the National Telephone Company have been duly considered. The committee have agreed to the following report:

1. The situation which has occasioned the provisional conclusion of the agreement referred to us as above is as follows: The license to the National Telephone Company to carry on telephonic business, either in London or elsewhere in the United Kingdom, is about to about to expire on Dec. 31, 1911. That company at present carries on about 90 per cent. of the telephonic business of the country. At the end of 1911, therefore, with the exceptions mentioned below, practically the whole of the facilities for telephonic communication now enjoyed by the public would, if nothing had already been done, and if nothing were to be done in the interval between now and then, entirely disappear. Exception has to be made in the case of a few provincial areas where municipalities have installed telephonic services in competition with the company under licenses which will expire at dates varying from 1913 to 1926.

2. The case of the district known as the London exchange area has already been provided for by an agreement dated Nov. 18, 1901, between the Postmaster-General and the National Telephone Company (herinafter called "the London agreement").

3. That agreement provided for the purchase of the plant of the company in the London exchange area on Dec. 31, 1911. Among other conditions, the plant was to be purchased at its value *in situ*, and no payment was to be made in respect of compulsory purchase, goodwill, or past or future profits. The company received underground facilities, and undertook to give intercommunication between the systems of the Postmaster-General and of the company in London during the continuance of the company's license, and to concede uniformity of rates.

4. The London agreement was never expressly submitted to Parliament, but is considered to have received parliamentary approval by the negativing of an amendment to the address on Jan. 27, 1902, and it has since been acted upon.

5. It is proposed by the agreement now referred to your committee to extend to the provinces, where the conditions materially differ, some of the principles of the London agreement.

6. The case of the provinces differs from that of London, chiefly in the fact that in certain provincial towns a municipal telephone system exists side by side and in competition with that of the National Telephone Company. These municipal systems are conducted under licenses from the Postmaster-General; and it is provided by the Telegraph Act of 1899 that where a municipality receives a license extending beyond Dec. 31, 1911, the license of the National Telephone Company to carry on business in the same area shall enjoy an extension for the same period. Another enactment of the Telegraph Act, 1899, provides that where in consequence of the grant of a license to a municipality the company obtain an extension of their license for as much as eight years beyond Dec. 31, 1911, they are bound (on certain conditions) to grant intercommunication within the exchange area.

7. The only places where the above enactments now have effect are the following:

Hull, whose license expires		Dec. 31,	1911.
Glasgow	,,	,,	1913.
Swansea	,,	,,	1920.
Brighton	,,	April 30,	1926.
Portsmouth	,,	July 30,	1926.

The resulting effect is that in Hull the municipal right to carry on telephonic business will expire at the same time as the company's right; in Glasgow, Swansea, Brighton, and Portsmouth the company's right will remain alive for various periods after 1911; and in Swansea, Brighton, and Portsmouth the company will enjoy the extended period subject to an obligation to give intercommunication to the subscribers to the municipal system.

8. Elsewhere than in the London area and the towns mentioned above, and the few places in which the Post Office are working telephonic services, the National Telephone Company is at present practically the only agency supplying telephonic facilities. It is to provide for the situation which will arise at the end of 1911 that the agreement of Feb. 2, 1905, was entered into between the Postmaster-General and the National Telephone Company. It will come into force on Aug. 31, 1905, if not previously disapproved of by the House of

Digitized by Google

Commons. For more convenient reference we append a copy of it to our report.

9. Broadly speaking, that agreement adopts the same method as was applied in the London area by the agreement of 1901. The Postmaster-General undertakes to purchase at the end of 1911 some, but not the whole, of the plant, land, and buildings that will then be in the hands of the company. The agreement contains provisions designed to secure that the property so taken over shall not be obsolete or otherwise unsuitable for the Postmaster-General's requirements. As to the sufficiency of those provisions, we shall have more to say hereafter. For the present, it suffices to note that the agreement contemplates the preservation of certain selected assets of the National Telephone Company, and the ensuring that they shall be made both available and useful to their successors. It follows that, so far as concerns those assets, the National Telephone Company is relieved of the otherwise difficult task of finding a purchaser, and their shareholders are relieved, as regards so much of their property, of the fear of losing it by the expiration of the license in 1911. In return, the company undertakes (besides the obligation of making and keeping their property good and serviceable for the purposes of the transfer in 1911) to give certain advantages not hitherto enjoyed by telephone users.

10. It should be mentioned here, as an exception to the provision that goodwill and profits shall not be considered in fixing price, that goodwill up to a maximum amount will have to be assessed on what is called the private wire business of the company, which the company give up under the agreement, notwithstanding that not requiring a license it could be carried on after 1911. Goodwill will also have to be paid for in the few cases of unexpired rights that the company will enjoy after 1911 in the areas of the competing municipalities mentioned above.

11. We have carefully considered the bearing of the agreement on the public interest, and to enable us to do so we have heard evidence as to the policy of the proposed purchase, as to the provisions in the agreement designed to secure that the assets to be taken over shall be properly selected and valued, and as to the possible consequential effects of the agreement on the interest of the public, whether regarded in its national capacity or as organised in municipalities which now carry on telephonic services or may in the future desire to do so. We have also considered the probable effect of the adoption of the agreement on the interests of the employés of the National Telephone Company.

12. On the general question of the policy of this purchase, protests were made not only by the present telephone-owning municipalities, but also on behalf of the London County Council, which claimed to represent one-fifth of the telephone users of the kingdom. Such witnesses have pointed out that the municipal services are both good and cheap, and that their competition with the National Telephone Company has greatly improved and cheapened the company's services in their areas. They have alleged that in London, where, under the agreement of 1901 the Postmaster-General has taken the field as a competitor of the National Telephone Company, the public has got a service neither so good nor so cheap as the municipal services. They have expressed fears that between now and 1912 it will be possible under the agreement for the National Telephone Company to institute so severe a competition with the municipal services as to starve them out of existence. And to prevent this, they have claimed that either the minimum rates allowed by the agreement should be fixed higher, or that favour or preference should be prohibited not merely, as under the agreement, between individual subscribers in the same area, but also between bodies of users in different areas.

13. But in the case of all the municipal witnesses it has become apparent that while they have been drawing our attention chiefly to the apprehended effects of the agreement during the intermediate and transitional period between 1905 and 1911, their chief fears have been as to its permanent effects after the disappearance of the company at the end of that time. They have pointed to the danger of their services being absorbed and superseded by the Post Office in a manner and on terms which would inflict financial loss on their ratepayers, inconvenience and detriment upon their constituent users, and an interference with that rapid development which they believe is fostered by municipal enterprise.

14. We are bound to say that some ground was given for these fears by the fact that the Post Office witnesses enunciated before us, as the present view of the Postmaster-General's department, the opinion that the Post Office should, after 1911, become the universal and exclusive provider of telephonic services in the United Kingdom. Among other things, the Postmaster-General had stated in a recent letter to Glasgow that "he did not anticipate any prolongation of existing licenses or otherwise," and Sir George Murray said "that it was desirable in the future that municipal telephones should be absorbed by the State." The case was not made better in this respect by the fact that these announcements were thought to be out of harmony with previous and even recent utterances of the same department. So recently as March 23, 1904, Lord Stanley, the present Postmaster-General, said in this House: "He would be only too ready to help in every way any municipality that wished to start its own telephones, and he hoped that the present difficulty, that a municipality could not get an extension beyond 1911 without the company receiving the same extension, might be overcome when they came to a general agreement." This policy, however, of unification under State management, though advocated by the Postmaster-General's witnesses, is not in the present agreement. It has been contended that one consequence of the agreement would be that during the transitional period 1905-1911 no fresh municipal licenses could be expected to be granted, nor could extensions of existing municipal licenses be promised.

15. We have not felt it necessary to go into the question of the comparative merits of municipal and national telephonic services, a question which we do not consider to have been referred to us. Nor have we followed up the controversies which arose as to the mechanical efficiency or financial stability of the existing municipal undertakings. For we felt no doubt that the relative claims of municipal and national systems will be settled by Parliament on higher considerations than that some municipalities may have made mistakes at their first essay. We express no opinion as to whether such mistakes have been made; but we see no reason to suppose that, even if they have, municipalities will not be able and willing to profit by the experience gained.

16. In favour of the general policy of purchase in 1911, the solicitor (Sir R. Hunter), the secretary (Mr. H. Babington Smith), and the engineer-in-chief (Mr. Gavey) to the Post Office appeared before us and, directing their attention mainly to the period 1905-1911, argued substantially as follows: (*a*) That the continuance, without break, of the supply of telephonic services after December, 1911, is secured in the best practicable way, without wasteful duplication of plant. (*b*) That a motive is provided and an enforcement secured for the maintenance of the company's plant in a fully efficient state. (*c*) That even if the company were left alone until their rights expire, no competitor could in the meanwhile make much profit who had not secured the intercommunication, which the agreement secures, with the company's subscribers. (*d*) That the agreement precludes preferential charges and unfair discriminations between subscribers in the same area. (*e*) That the rates charged by both Post Office and company will be confined within maximum and minimum limits. (*f*) That the experience gained under the London agreement showed that its policy has been justified by success. In two years 44,000 new subscribers (equally divided between the two systems) had been added. (*g*) That the immediate erection of new plant by the Postmaster-General, even if not financially imprudent, could not, except under extreme pressure, be accomplished in the time available before the disappearance of the company's system. (*h*) That the fullest right of starting or licensing competitive systems is an added guarantee of efficiency, and is made effective by the right of intercommunication, without which competition could not pay. (*i*) That it would be a proper course for the Post Office to acquire any municipal exchange which is unable to maintain itself against the competition of the company.

17. By way of securing that the assets to be bought by the Postmaster-General shall be properly selected and valued the agreement in the first place (Clause 4) makes all questions of price in case of disagreement the subject of arbitration. Except in the few cases mentioned in paragraph 10 of this report the price will receive none of the enhancements that usually attend a statutory expropriation. Many indeed of such elements of added price are expressly negatived. The words of Clause 4 (1) are as follows: "4. (1) The value on Dec. 31, 1911, of all plant purchased by the Postmaster-General in pursuance of the provisions hereof shall be deemed to be its fair market value at the time of the purchase due regard being had to the nature and then condition of such plant and to the state of repair thereof and to the circumstance that it is in such a position as to be ready for immediate working and to its suitability for the purposes of the Postmaster-General's telephonic service and no addition shall be made to such value in respect of compulsory purchase or of goodwill or of any profits which might have been or be made by the company by the use of such plant and in determining the value of any plant no advantage arising from the construction of such plant by leave of the Postmaster-General upon any railway or canal over which the Postmaster-General possesses exclusive rights of way for telegraphic lines shall be taken into account."

18. The words "fair market value at the time of purchase" are identical with those used in the London agreement (Clause 9 (3)). They occur also in the corresponding part (Clause 30) of the licenses usually granted to municipalities, of which the model form as revised in 1902 is printed in the appendix. Some exception was taken to these words on the ground that they differed from those employed in the Tramway Act of 1870. The words there were "the then value." These became the subject of a judicial decision of the House of Lords to the effect that they excluded past or future profits and compensation for compulsory sale, and fixed the proper value of the property in question at such sum as it would cost to con-

Digitized by Google

struct and establish the same, less an appropriate deduction in respect of depreciation. We regard it as important to secure the adoption of the words which carry the authority of a legal decision. We, therefore, recommend that Clause 4 (1) in the agreement should be so amended as to run as follows: "1. The value on Dec. 31, 1911, of all plant, land, buildings, stores, and furniture purchased by the Postmaster-General in pursuance of the provisions hereof shall be the then value (exclusive of any allowance for past or future profits of the undertaking or any compensation for compulsory sale or other consideration whatsoever) of such plant, land, buildings, stores, and furniture having regard to its suitability for the purposes of the Postmaster-General's telephonic service and in determining the value of any plant no advantage arising from the construction of such plant by leave of the Postmaster-General upon any railway or canal over which the Postmaster-General possesses exclusive rights of way for telegraphic lines shall be taken into account." This involves the consequential deletion of Clause 4 (2).

19. We are unable to suggest a better method than arbitration for settling the purchase price in case of disagreement. The process of arbitration has, however, to be applied to the determination of other questions besides that of price. The agreement proposes to resort to it for the purpose of testing plant in some instances in respect of its "suitability for the requirement of the telephonic service of the Post Office." In respect of these cases we should mention that it has been contended before us that the Postmaster-General should be his own judge of suitability. It becomes necessary, therefore, to examine the provisions of the agreement under which it is designed to effect a proper discrimination between the assets to be taken over.

20. From an examination of Clauses 2 and 3 of the agreement it appears that, except as mentioned below, the Postmaster-General will, as regards every item that he has to buy, have the protection afforded by the fact that either (*a*) it has been acquired or constructed with his consent, or (*b*) it comes up to the scheduled specification in point of technical efficiency, or (*c*) it is found by an arbitrator to be suitable for the Postmaster-General's requirements. The exceptions to the above are (i.) land or buildings acquired before the agreement in non-competitive areas, if in use on Feb. 2, 1905; (ii.) plant acquired before the agreement, not coming up to specification, and being switchboards or other internal plant in use in non-competitive areas on Aug. 15, 1904, and specified in list by company to Postmaster-General before Aug. 2, 1905. All plant, land, and buildings must in order to be qualified for purchase be actually "in use" by the company on Dec. 31, 1911, for the purpose of the licensed telephonic business of the company (see Clause 2 [1A]). So that it may be remarked of (i.) *supra* that land or buildings bought or erected before Feb. 2, 1905, in use then, and still in use nearly seven years later, are not very likely to be not worth taking under the carefully guarded conditions of the arbitration. And as regards (ii.) it is to be remarked that these classes of assets will also have to be still "in use," under Clause 2 (1A), on Dec. 31, 1911, and that should they be then worn out, obsolete, or otherwise unsuitable, the want of newness or the unsuitability can still be urged before the arbitrator in reduction of the price. The switchboards and other plant mentioned in (ii.) were stated before us to amount to not more than 1 per cent. of the whole amount of plant to be purchased.

21. A variety of detailed objections were taken to many of the provisions of the agreement, in respect of which it was sought to show that the terms of purchase were too favourable to the National Telephone Company, and that this was evidenced by a substantial rise in the value of the company's stocks as between certain dates. No doubt it would be possible to bring to an end the existence of the company in ways which would have been most unfavourable to the company. Had that been the Postmaster-General's object he could doubtless have aimed at it by settling in his own favour every point which tended in that direction. Indeed, he could in that case have done without the company's plant, and he could have done without an agreement altogether. But it does not follow that by so doing he would have furthered the interest of the public. Loss to the Telephone Company's shareholders is not necessarily and in any event gain to the public; and putting an end to the company's existence is not the only thing that the public interest requires. The main interest that the public have is in the maintenance of a cheap efficient and improving service without break of continuity.

22. In the course of these criticisms it was sought to show that the specifications in the third schedule to the agreement were not of adequate stringency to secure that the plant taken over should be modern and efficient. In particular it was contended that the specifications of this agreement were less stringent than the corresponding requirements attached as conditions to licenses granted to municipalities. The questions here involved were of necessity highly technical, and our task was not rendered easier by the fact that we had not before us the evidence of any witness who had not been employed either on the installation of the Post Office or on those of the telephone-owning municipalities. Neither side called an independent expert. The case for the Post Office with respect to the specifications was that they represented the latest standard practice, not merely of the National Telephone Company, but of the Postmaster-General's own telephone system; and that they followed the better and more modern practice of specifying results (such as audibility, etc.) to be aimed at, without too greatly limiting discretion as to how those results were to be attained. Indeed, it was said that it was intended to alter in the same direction the corresponding specifications in the municipal licenses.

23. If the price to be paid is not excessive and the specifications and other safeguards are sufficient to secure that the plant shall be good, the only question that remains is whether it would be possible and, if possible, better for the telephone users and the taxpayers for the Postmaster-General to provide his own plant.

24. On the question of possibility, the Post Office witnesses estimated that at least six or seven years would be required to construct a plant which, when completed, would be equal to three times the capacity of that now owned by the National Telephone Company, which is estimated to be the minimum probable requirements of 1911. For the weighty reasons appearing in the answers to Questions 200-203, the Postmaster-General has not availed himself of the option that was open to him on Dec. 31, 1904, to give six months' notice to purchase the undertaking of the company. He has, therefore, only the period from the present time to Dec. 31, 1911, in which to replace with all their accessories the 250,000 telephones that the National Telephone Company had in the provinces on March 31, 1905, besides creating the large additional number that will be wanted by the beginning of 1912. It is fair to mention that Mr. Bennett, the engineer to the telephone-owning municipalities, estimated that this work could be accomplished in four years. In this period, however, he had made no allowance for the time likely to be occupied in the compulsory acquisition of lands.

25. But even if it were possible to complete this duplicated installation by the beginning of 1912, it must be borne in mind that from now till then, should the policy of duplication be preferred to that of the agreement, the telephone users of the one system will get no intercommunication with those of the other; and those of the company's system in areas in which the Post Office have not set up competition will have to submit to whatever high rates, preferential charges, and other vexatious treatment it may be competent to the company in the exigencies of conducting an expiring business to impose upon them. At the same time the taxpayer will for some time have to go without interest on the necessarily large sums that will have to be raised for the purpose of equipping and starting the new service.

26. The cases of Glasgow and Hull present some special features. Glasgow (in the year 1900) took a license expiring in 1913. Hull (in 1902) took a license expiring in 1911. In both cases it was represented to us that the short term was accepted in the expectation that the Government, having thereby been spared the inconvenience of the consequent prolongation of the company's license, would recognise the forbearance of those municipalities by renewing their licenses in 1913 and 1911 respectively. In the case of Hull it was even said that at an interview with the Postmaster-General in 1901 a renewal had been expressly promised. After hearing some of those present at that interview on both sides, we found that, though there was no substantial conflict of testimony as to the words used, there were irreconcilable differences of opinion as to the inferences to be drawn. In any case Hull had felt so far encouraged by what had passed as to feel justified in going forward with the installation of a competing system with no better security for their hope that the license would be extended beyond 1911 than assurances said to have been given in a conversation never reduced to writing. Both Hull and Glasgow professed, therefore, to have received with surprise and some sense of hardship the subsequent uncompromising pronouncements of the Post Office in favour of the unification of all services under the management of the State. We think that these two cases should receive special consideration in the event of any parliamentary action being taken such as we foreshadow in paragraph 28.

27. On a careful review of the bearing of the agreement as a whole upon the interest of the public, we find that the policy of purchase is to be preferred to the other alternatives; and that if safeguarded as we recommend in paragraph 28 it will leave the position of the municipalities unprejudiced as regards the period succeeding the cesser of the company's rights in 1911. We are of opinion that in order to make it clear that municipal licenses can be granted between Aug. 31, 1905, and Dec. 31, 1911, without giving the National Telephone Company rights to compensation under the Telegraph Act of 1899 in respect of licenses granted after Aug. 31, 1905, it is desirable that the agreement should be modified by omitting on p 6, paragraph 2 (1) *b*, line 6, the word "whether" and the words "or after." After allowing due weight to the criticisms that

Digitized by Google

have been passed upon details, we think that the agreement provides on balance the best security available in the circumstances that the property purchased shall be good and suitable in quality, and that no more than a reasonable price shall be paid.

28. While, therefore, we recommend that, in the general public interest, the House of Commons should not disapprove of the agreement, we think that the agreement, with the modifications that we have proposed, should not be allowed to become operative until a pledge has been given to the House that between now and January, 1912, nothing shall be done by the Government whereby the question of the future ownership and management of local telephone installations (as distinct from the ownership and management of trunk lines) may be prejudiced; and that, unless by a vote of the House it has otherwise been determined, the Post Office shall continue to grant licenses to municipalities on terms not more onerous in respect of royalties than the terms of the standard telephone license as revised in January, 1902.

29. We recommend that the purchase of any plant by the Postmaster-General from the municipalities shall be governed, if the municipalities so desire, by Schedule 3 attached to the agreement.

30. We also suggest the following amendment to the agreement: add to Clause 9, line 4, after the word "exchange," the words "or any municipal system established under a license granted after Aug. 31, 1905."

31. We pass to the consideration of the probable effects of the adoption of the agreement on the interests of the employés of the National Telephone Company. We interpret this part of the reference to us as meaning that we should inquire whether those employés will, if the agreement becomes binding, be thereby placed in a substantially worse position than that which they occupied on Feb. 2, 1905. We have heard evidence on this subject from the secretary to the Post Office, the manager of the National Telephone Company, and representatives of the workpeople and others on their behalf. The total number of employés at present is 14,227, which, it is anticipated, will have been largely increased in 1911. The claims put forward on behalf of the staff were, mainly, for a guarantee of continuity of employment when the service is taken over by the Postmaster-General, compensation for loss of office for those whose services are not retained, and a claim to pensions. Those members of the company's staff with a salary of £100 a year and upwards, who at present number about 1,200, and are beneficiaries in a pension scheme started by the company in 1896, which is secured by a trust deed and financed by a contribution of 2½ per cent. from salaries and a like amount contributed by the company, asked that the assets and liabilities of the pension fund should be taken over and the fund continued on its present basis, and be kept alive for the benefit of its members, or, alternatively, that the Postmaster-General should take over the assets of the scheme and count the employés' years of service with the company for superannuation purposes as if they had been spent in the service of the State. Unless something of this kind were done, it was stated, the staff would lose considerably by the transfer. Operators and others who, had they been employed in the Civil Service, would have been entitled to superannuation benefits have asked that their years of service with the company shall, on their being taken over in 1911, count as if spent in the Civil Service. In support of these claims Mr. Gaine, the general manager of the National Telephone Company, stated that unless they were conceded the effect would be very detrimental to the telephone service, since the class of people required would not offer themselves for training in a concern where they had no safety for continuity of service. Further, that the constant development of the telephone system would speedily absorb any surplus which might be caused in the Post Office by taking over the entire staff. In this latter view Mr. Babington Smith concurred, and further stated that the Postmaster-General had in effect given an assurance that in 1911 the existing staff would be taken over *en bloc*.

The only clause in the agreement which deals with the case of the staff is Clause 8. By that clause the Postmaster-General has reserved a free hand; but he has given certain assurances to deputations of employés. It is clear from the tables of wages presented to us by the National Telephone Company and by the secretary to the Post Office, and from the evidence, that the terms of employment under the Post Office, having regard to the conditions of service, are very similar to those of the company, and it has to be remembered that the employés of the National Telephone Company, including the pensionable class, have entered on their employment subject to a liability to be dismissed on notices varying from a week to a month, and also with a knowledge of the fact that the license to the National Telephone Company expires in December, 1911. Having regard to these facts, we recommend as follows: (*a*) All officers and servants who shall have been not less than two years continuously in the service of the company on Dec. 31, 1911, shall as from that date become officers and servants of the Postmaster-General on the terms of hiring and conditions of employment which obtain in the grade to which they are transferred. (*b*) Such officers and servants as are not beneficiaries of the pension scheme of the National Telephone Company, but who, if in the service of the Postmaster-General, would be on the established list, on entering the service of the Postmaster-General shall, for the purpose of superannuation and of being placed on the established staff, be entitled to count their past years of continuous service with the National Telephone Company, subsequent to 1899, as years passed in the Civil Service of the Crown. (*c*) The company should be required to submit all candidates for the National Telephone Company's service from Aug. 31, 1903, to the same, if any, medical examination as that required for officers and servants entering the Government service in the same grade. And we recommend that employés of any class now in the service of the company, and in their service on Dec. 31, 1911, should, if taken over by the Post Office, not be required to submit themselves to medical examination.

We recommend an undertaking by the Postmaster-General that no servant of the company taken over by the Post Office shall suffer by this transfer whenever it takes place—*i.e.*, that the employés of the company shall have the option of either continuing on the same terms as to pensions which they now enjoy under the company, or adopting the superannuation terms and conditions of the Post Office service.

Having regard to what we have recommended, and assuming that those recommendations are carried out, we do not think that the coming into operation of the agreement will place the staff in any worse position than that in which they stood on Feb. 2, 1905.

LEGAL INTELLIGENCE.

VIBRATION FROM ELECTRICITY WORKS.

At the Manchester Assize Courts last week Mr. A. Hopkinson, K.C., the deputy of the Chancellor, had before him two matters—Harter *v.* Manchester Corporation and Sillitoe and Soares *v.* Manchester Corporation—which arose out of alleged excessive vibration at the Dickinson-street electricity works. The litigation was begun in 1902, but there have been various adjournments for the purposes of improvements being made in the machinery complained of.

Mr. MABERLY, who appeared for the defendants in both matters, explained that the present application was that an order to stay proceedings be taken on an agreement come to between the parties.

Mr. GRANT, who represented the plaintiffs, stated that in Harter's case judgment had been already given, but the order now taken would finally close the action.

An order staying proceedings was accordingly made in both cases.

ELECTRICITY IN MINES.

At Wakefield last week Mr. William Stewart, as manager of the Crigglestone Colliery Company, was summoned for having failed to see that a coal-cutting machine was so worked and maintained as to reduce the danger from accidental shock or fire to a minimum, and further with failing to have the underground cables suspended by leather or other flexible material.

Mr. W. M. GICHARD, who prosecuted for the Home Office, said that on the night of June 2 an explosion of gas occurred in Crigglestone colliery, caused by one of the coal-cutting machines, the switch-box of which was afterwards found to be defective through the absence of the indiarubber ring through which the electric cables ought to pass.

The defence was that a manager could not be held responsible for every trifling dereliction of duty on the part of those engaged in the mine.

The charge of non-suspension of the cables upon flexible material was dismissed, but on the other summons the Bench held the defendant responsible, and imposed a penalty of £5 and costs.

PERSONAL.

The Gloucester City Council have been recommended to increase the salary of Mr. Bache as city electrical engineer from £300 to £325 for the current financial year, and to give him an additional increase of £25 a year for each of the two following years, on the understanding that such increasing salary will be accepted by Mr. Bache in satisfaction of the special services rendered and to be rendered by him in connection with the light railways and the extensions now being carried out at the electricity works.

Mr. H. A. Harding, of the Leatherhead Electricity Supply Co., has been appointed assistant electrical engineer to the Acton Urban District Council. There were 114 applications for the appointment.

A hundred friends of Mr. W. S. Doran assembled last Thursday night at the Hotel Cecil to give him a farewell dinner previous to his departure for the United States, where he intends to take up his residence. Mr. Doran was formerly with the Worthington Pump Co., but has been associated for the last few years with the Westinghouse interests in this country. His genial manner has gained him many friends, and he will be greatly missed by all those who have come into contact with him.

COMPANIES' MEETINGS AND REPORTS

METROPOLITAN RAILWAY.

The half-yearly meeting of this Company was held on Tuesday at the Cannon-street Hotel, Sir Charles M'Laren, M.P., presiding.

The CHAIRMAN, in moving the adoption of the report, which recommended a dividend on the ordinary stock for the past half-year at the rate of 2½ per cent. per annum, said they had not only carried an increased number of passengers during the half year, but there had been an increase in the money taken from fares. They had made some alteration in the classes consequent upon bringing into traffic the new electrical cars, which were of two classes only, and, therefore, between all stations from Baker-street to Harrow and Uxbridge, and from those stations to the Circle, they only now issued first and third class tickets. They would do the same thing as regarded persons travelling between Hammersmith and stations on the Circle as soon as the electrical service was in full working on that line. They would further only have two classes between Harrow and Verney Junction in the near future. The directors of the Metropolitan Company had revised their fares to some extent, and probably a further revision might be advisable, especially as they found that what they had done had been a success. The cost of making the change from steam to electricity was proving to be somewhat greater than the Board at one time thought, but they were perfectly satisfied that they had taken the right course, and believed they would, in a short time, reap the benefit of it. They were passing through a very trying half-year, because they had not yet wholly surmounted the difficulties of transition, and in the course of a few months the new joint line of the Great Western and Great Central Companies might be ready for opening, and some of the Great Central trains which now passed over the line would be diverted to it. The company commenced on Jan. 1 to run some electric trains between Baker-street and Harrow, and between Harrow and Uxbridge. They gradually increased the number of these trains until the whole of the service on the extension lines between Baker-street and Harrow and Uxbridge was now worked electrically, though trains from Baker-street to and from stations beyond Harrow on the Aylesbury line were still worked by steam. They had had some few failures and stoppages while bringing in the electrical service, but nothing of a serious character, and certainly nothing more than might be regarded as inevitable in the making of so radical a change. With regard to the working of the Circle, by agreement with the District Company, the Company made arrangements to commence to work all the trains on the "up" road electrically on July 1, but unfortunately the service over the District Company's part of the Circle line had to be discontinued in the course of a few hours, as certain difficulties became apparent in connection with the conductor rails and car equipments. The matter had been, and still was, in negotiation with the District Company, with a view to deciding upon the necessary slight alterations to be made, and they hoped to be in a position very soon to resume continuous working round the Circle with electric trains. In the meantime they were running a service of electric trains between 7 a.m. and midnight, in addition to the ordinary service of steam trains, on their portion of the Circle — viz, between South Kensington and Aldgate, *via* Paddington.

The report was adopted.

CITY AND SOUTH LONDON RAILWAY.

The half-yearly general meeting of this Company was held on Tuesday, Mr. C. J. Mott presiding. Particulars of the report appeared in our last week's issue.

The CHAIRMAN stated that there had been a decrease in the number of passengers carried of 564,399 and in traffic receipts of £4 677. The total decrease in receipts was £4,041, and the amount available for dividends showed a diminution of £1,485. The competition of the London County Council electric trams had affected them principally. They had practically annihilated their 1d. fares on the part of the line where they ran. He believed, however, that the tramways had done their worst. Their long-distance fares now constituted the bulk of their traffic, and those could not be touched by the trams. They did not think they had much to fear from the motor omnibuses. He thought that in many cases they would bring traffic to the railway. The reduction of fares had not met with a satisfactory result. They had not lost anything, but they had had to carry a great many more passengers. It might be that in the future they would get some return.

The report was adopted.

DISTRICT RAILWAY.

The half-yearly meeting of this Company was held on Wednesday, Mr. R. W. Perks, M.P., presiding in the absence, through ill-health, of Mr. Chas. Yerkes. Particulars of the report were given in our last week's issue.

The CHAIRMAN stated that the extension of the electrical service was steadily proceeding, and in five weeks the Board hoped to begin the Wimbledon service, which would leave only the Inner Circle and the North-Western trains not propelled by electricity. Until all steam trains had been removed they could not institute automatic signalling, which was a necessary prelude to the Company having the frequent service for which provision had been made. He saw no reason to depart from the figures which had been set forth before Parliament, that the Company would carry a hundred million passengers a year, and some thought that that total would be largely exceeded. The shareholders had paid for a large amount of the equipment of the line in ordinary and preference stocks issued at a discount, and as reference was frequently made to the subject he would like to say that the discount at which the Underground Company had taken those stocks represented, he thought, a higher price for the stocks than the bulk of the ordinary proprietors in the Company had paid for their holdings. Practically the whole of the former proprietors who bought their stock at high prices had sold out long ago, and at the present time the holders consisted almost wholly of people who had bought their stock within the last 20 years at prices ranging from 25 to 36 or 37. Therefore, when it was said that the Underground Electric Railways Company of London would be making large profits it was as well to remember that that company had bought its stock at very much the same price as the other proprietors. The zone fares, which would represent a very large reduction—2d. from Hammersmith to Aldgate and 3d. from Ealing or Putney to Aldgate—would not come into operation until the whole system was electrified.

The adoption of the report was approved without discussion.

CENTRAL LONDON RAILWAY.

The half-yearly meeting was held on Wednesday, Sir Henry Oakley presiding. Particulars of the accounts appeared in our issue of last week.

The CHAIRMAN, in moving the adoption of the report, stated that in the aggregate the passengers had increased by over 60,000, but while the ordinary traffic had risen by 80,000, the workmen traffic had, curiously enough, fallen off by some 30,000, which was a matter for surprise, considering the favourable terms they are carried upon. The earnings were 5s. 6d. per mile, which was the highest figure attained, except in Coronation year, when it rose to 5s. 6½d. The working expenses remained stationary. The Board had considered the report of the London Traffic Commission, but had no definite suggestions to make regarding same at the moment. Arrangements have been concluded with the Great Western Railway for through bookings to certain of the latter's suburban stations. The matter of ventilating the tube is to receive further consideration.

The report was adopted.

ANGLO-AMERICAN TELEGRAPH.

The report states that the total receipts from Jan. 1 to June 30, including the balance brought forward, amounted to £183,678. The traffic receipts show an increase of £15 711 as compared with the half-year ended June 30, 1904. The working expenses of the half-year, including expenses of steamship "Minia," pensions account, etc., amounted to £70,925, being an increase of £7,346. The directors have set apart the sum of £10,000 to the renewal fund, leaving a balance of £102,752. Quarterly interim dividends of 15s. per cent. on the ordinary stock and of £1. 10s. per cent on the preferred stock were paid on May 1, 1905, absorbing £52,500, and second quarterly interim dividends of 14s. per cent. on the ordinary stock and £1. 8s. per cent. on the preferred stock, amounting to £49,000, will be paid on Aug. 5. The balance of £1,252 will be carried forward.

CHATHAM AND DISTRICT LIGHT RAILWAYS.

The report for the half-year ended June 30 last, to be presented to the meeting on 18th inst., states that the receipts were £16,611 and expenses £10,370. Adding the balance brought forward (£1,700) and deducting the interest on debentures (£1,000) there is £6,940. The directors recommend a dividend at the rate of 5 per cent. per annum on the ordinary shares for the half-year, carrying forward £2,568. The directors regarding this as an interim account, have made no provision for depreciation, and, as usual, postpone doing so until the final account is made up at the end of the year. The receipts continue to show satisfactory progress. By resolution passed at an extraordinary general meeting, held on April 12 last, the raising of additional capital to the extent of £61,000 was authorised. Of this amount £57,500 has been issued, half in preference shares and half in ordinary shares of £10 each, and has been fully paid up. Out of the proceeds the Lloyd's bonds appearing in former accounts to the value of £19 533 have been paid off and cancelled, and the Company has also paid off over £30,000 to creditors for new cars, and extension to Rochester, and parliamentary and other expenses in connection with the Act of 1903. Five new cars have recently been put in service, and it is anticipated the receipts for the current half-year will show still further improvement.

GREAT NORTHERN AND CITY RAILWAY.

The report of the Great Northern and City Railway Company for the half-year ended June 30 last, to be submitted at the meeting on Aug. 4, states that the total revenue receipts for the six months amounted to £46,239, as against £36,509 for the previous six months. The number of passengers carried for the same periods, excluding season-ticket holders, were 6,391,574 and 5,227,595 respectively. The number of local season tickets issued during the half-year was 2,913 as against 2,511 for the half-year ended Dec. 31, 1904. The number of three-route season-ticket holders using the Company's line during the past half-year was 2,547. The number of through bookings from the Company's stations over the Great Northern and the City and South London Railways is steadily increasing.

DUBLIN AND LUCAN ELECTRIC RAILWAY.

The report for the half-year to June 30 states that the receipts and disbursements respectively are nearly identical with those of the corresponding period of last year. After providing for debenture interest there is an available balance of £1,249. 6s. 5d., out of which the directors recommend the payment of the usual half-yearly dividend

Digitized by Google

(£2475) on the 5 per cent. preference shares, and of three months' (£237. 10s.) arrear of dividend on those shares. Also that £400 shall be paid to the contractors on account of the principal sum remaining due to them for electrical equipment, and that the balance of £136. 16s. 5d. shall be carried forward to next half-year. The above-mentioned payments of £237. 10s. and £400 will clear off all arrears of dividend on the preference shares to June 30, 1905, and reduce the electrical equipment debt to £1,600.

NEW COMPANIES REGISTERED.

Para Electric Railways and Lighting Co., Limited.—Capital, £700,000. Objects: to acquire from the Works Construction Co., Limited, the existing tramway and electric lighting undertakings of the Companhia de Estrada de Ferro Paraense, of Pará, and a provisional concession of Jan. 27, 1905, granted to C. H. C. Moller by the municipality of Pará to construct or acquire and work tramways, railways, and electric lighting and power supply works and undertakings in Pará or elsewhere in Brazil, etc. Registered office: 75, Lombard-street, E.C.

Bombay Hydro-Electric Syndicate, Limited. — Capital, £15,000. Objects: to adopt an agreement between D. J. Tata and E. Miller on behalf of themselves, and also on behalf of R. J. Tata, J. W. Brown, and D. E Gostling, to produce, generate, accumulate, store, acquire, utilise, supply, apply, employ, distribute, sell, lease, or otherwise dispose of electric current, power, and energy, and to carry on the business of engineers or contractors in all its branches.

Liens Registered.

Kent Electric Power Syndicate, Limited—A mortgage or charge on the company's undertaking and property, present and future, including uncalled and unpaid capital (if any) dated July 3, 1905, to secure £750, has been registered. Holders: The Hon. J. B. Lubbock and G. C. Curtis, 15, Lombard-street, E.C.

Perth Electric Tramways, Limited, London, E.C. — Lien registered July 27, for £3,000 debentures, part of £50,000; amount previously issued, £36,000; charged on the tramways and tramway undertaking, plant, machinery, etc., in Perth, Western Australia.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Warrington. — Tenders are required for cables. Tenders by Aug 11.

Sophia.—The District Finance Commission require tenders for telegraph material by Aug. 25.

Florianopolis (Brazil).—The Municipality require tenders for the lighting of the town by Oct. 2.

Turnu-Severin (Roumania).—The Mayor invites tenders for the electric lighting of the town. Tenders by Sept. 10.

Olympia 1905 Exhibition.—The Executive Committee invite tenders for the loan or hire of 300-kw. direct coupled steam set.

Madrid.—The Public Works Department require tenders for the construction and working of an electric tramway in Zaragoza. Tenders by Sept. 12.

Madrid.—The Public Works Department require tenders for the construction and working of an electric tramway in Malago. Tenders by Aug. 19.

Madrid.—The Public Works Department require tenders for the construction and working of two electric tramways in Barcelona. Tenders by Aug. 18.

Brussels.—The Government Telegraph Department require tenders for 14,700 pine telegraph poles. Specification 76 may be obtained from their office at Brussels. Tenders by Aug. 9.

Acton.—The Urban District Council invite tenders from manufacturers for the supply of arc lamp carbons and house fuse-boxes for a period of 12 months. Tenders by Aug. 21. See advertisement.

Paris.—The Post and Telegraphs Department require tenders for tubes for telephone and telegraph cables. Specifications from the above office, First Bureaux, 103, Rue de Grenelle. Tenders by Aug. 7.

Alicante (Spain).—The Harbour Board (Junta des Obras del Puerto) require tenders for two electric cranes, capable of lifting 10 000 ko. and 1,500 ko. respectively. Tenders by Sept. 15. Estimate, 107,010·10 pesetas.

Dublin.—The Lighting Committee of the Corporation invite tenders for certain alterations and additions to the coal storing and conveying plant at their Pigeon House generating station. Tenders by Aug. 15. See advertisement.

Swansea.—The Corporation invite tenders for supply, delivery, and erection of one intercommunication switchboard section for central exchange, and apparatus for sub-exchanges at Morriston and Mumbles. Tenders by Aug. 11.

Calanas (Spain).—The Municipality require tenders for the installation and working for 10 years from Jan. 1, 1906, of the electric lighting of the town. Tenders by July 27 to the Alcalde of Calanas, province of Huelva, Spain.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

Merthyr Tydfil.—Tenders are invited by the Urban District Council for the erection of refuse destructor plant capable of effectually burning 120 tons of refuse per day, together with all buildings and contingent works connected therewith. Tenders by Sept. 1.

Fulham.—The Council invite offers for a 300 kw. horizontal compound condensing slow-speed set with condenser complete, consisting of Musgrave engine fitted to a General Electric Co.'s alternator, speed 95 r.p.m. Offers to the Town Clerk by noon on Aug. 16.

Ebbw Vale (Mon.)—Tenders are invited for the following, for the Ebbw Vale Urban District Council: (Section A) cables; (B) overhead lines; (C) street lamps and fittings; (D) meters. Specifications, etc., may be obtained at the offices of the consulting engineer, Mr. Reginald P. Wilson, 66, Victoria-street, Westminster. Tenders to the Clerk of the Ebbw Vale Urban District Council by 12 noon on Aug. 5.

Erdington.—Tenders are required for the construction of Section No. 1 of the Erdington tramways, comprising the laying of the permanent way, including copper bonding, wood block paving, and other works incidental to the laying of about 2½ miles of double-track tramway, for the Tramway Committee. Tenders to the joint engineers, Mr. Robert Green (of Messrs. Pritchard, Green, and Co.), of 37, Waterloo-street, Birmingham and Mr. Herbert H. Humphries, engineer to the Council, Public Hall, Erdington.

Municipal Board of Mussoorie (India).—The Municipal Board invite tenders for the supply, delivery, and erection at sites, in complete working order, of the following plant: (*a*) steel power pipes; (*b*) water-motors; (*c*) alternators with exciters; (*d*) switchboards with instruments and apparatus; (*e*) transformers; (*f*) induction motors; (*g*) pumps; (*h*) workshop machines. Also for the supply and delivery of the following: (*a*) bare copper wire for overhead mains; (*b*) insulators and lightning arresters; (*c*) arc and incandescent lamps; (*d*) telephone equipment; (*e*) workshop tools; (*f*) general stores. Specifications, form of tender, and general conditions can be obtained on application to Mr. C. H. Shanan, municipal electrical engineer, Municipal Office, Mussoorie, India (telegraphic address, Shanan, Mussoorie), on payment of a deposit of Rs.75 (£5), which amount will be returned on receipt of a bona fide tender. Tenders by Oct. 23. See advertisement.

Madrid.—The Director-General of the Telegraph Department, Carretas 10, Madrid, invite tenders for the supply of 50 tons of galvanised iron wire, 4mm. in diameter, and 5 tons of bronze wire, 2 mm. in diameter. The maximum price at which tenders will be received is 1,570 pesetas (about £47) per ton for galvanised iron wire, and 3,450 pesetas (about £108) per ton for bronze wire. A deposit of 5 per cent. of the value of the goods at the upset price is required to qualify any tender. N.B.—It is notified from H.M. Embassy at Madrid that a foreigner, when entering into contracts for the performance of public works in Spain, must renounce by public act all rights to which he might be entitled by virtue of the law of his own country in so far as his contract is concerned, and accept any administrative decisions that may be issued respecting questions arising from that contract. In entering into such contracts a local agent is a practical necessity. Tenders by Aug. 19.

RESULTS OF TENDERS.

Bury.—The Corporation have accepted the tender of Triumph Stoker, Limited, of London and Leeds, for stokers for the electricity works.

Redditch.—The Urban District Council have accepted the tender of A. G. Avery, at £144. 10s., for the erection of a pump-house at the electricity works.

Bolton.—The Corporation have accepted the tender of Triumph Stoker, Limited, of London and Leeds, for two mechanical stokers for the electricity works.

Bath.—The Town Council have accepted the tender of Mr. C. Wibley, amounting to £227, for work necessary for the accommodation of the new storage battery.

Islington.—The Borough Council have accepted the tender of R. Cutting and Co., at £70, for the stopping of a crack in the chimney shaft of the new boiler-house at Elen-grove.

Gloucester.—The Electricity Supply Committee have recommended the Council to accept the quotation of Messrs. Crompton and Co., at £372. 15s. 6d., for extension of buildings and plant at the electricity works.

Cables, etc.—Messrs. Johnson and Phillips, Victoria Works, Old Charlton, Kent, have received the following contracts: hot wire ammeters and transformers for the County of London Electric Supply Co.; cables (concentric, for C.C. system) and flexible wires for one year for the Metropolitan Asylums Board; and 8 miles $^{7}/_{23}$ V.I.R. cable for the G.P.O. Telegraphs Department.

Islington.—The Electricity Committee have received the following tenders for the supply of steam turbo-generators:

Mather and Platt	£14,600	0	0
British Thomson-Houston Co. (Mirrless-Watson condenser)	10,064	0	0
Ditto (Worthington condenser)	9,682	0	0
Ditto (Allens condenser)	9,680	0	0
Bruce Peebles (Parsons turbine)	9,750	0	0
Ditto (Brush turbine)	8 811	0	0
Ditto (Richardson-Westgarth turbine)	8,170	0	0
Willans and Robinson (Bruce Peebles alternator)	9,078	0	0
Ditto (General Electric Co. alternator)	8,341	0	0
Ditto (Dick-Kerr alternator)	8 258	0	0
Brush Engineering Co.	8,477	0	0
British Westinghouse Co.	8,430	0	0
C. Parsons and Co.	8,405	0	0
General Electric Co. (Parsons turbine)	8 192	10	0
Ditto (Brush turbine)	7,445	0	0

The engine offered by Messrs. Willans and Robinson for a Willans-Parsons turbine coupled to a Dick-Kerr alternator, has been recommended for acceptance.

Digitized by Google

London County Council.—The Bridges Committee have received the following tenders for the reconstruction of four bridges carrying the Albert Embankment road over certain dock entrances, and for the reconstruction of Mill Pond Bridge in Nine Elms lane in connection with the reconstruction of the tramways:

A. Fasey and Son*	£3 314	18	3
T. W. Pedrette	3,428	7	6
Muirhead, Grieg and Matthews	3,428	11	6
Cochrane and Sons	3 444	15	5
Pedrette and Co.	3 612	0	0
Butler and Co.	3 529	5	6
Baker and Co.	3 660	3	6
Kavanagh and Co.	3 695	8	9
Heenan and Froude	3,783	0	6
Westminster Construction Co.	4,227	10	9
Mowlem and Co.	4,537	0	0

The amount of the estimate of the cost of the work was £3 835. 2s. 6d.
*Recommended for acceptance with power to sublet the steelwork.

The Highways Committee have received the following tenders for the execution of the roadwork and platelaying in connection with the construction or reconstruction for the underground conduit system of electrical traction of the tramways:

R. W. Blackwell and Co., London	£96 202	4	6
Dick, Kerr, and Co., London*	96,242	3	7
J. Mowlem and Co., London	95 384	0	0
W. Griffiths and Co., London	97,091	1	5
J. G. White and Co., London	98,478	9	6
Muirhead, Greig, and Matthews, London	99 893	7	2
T. C. Starkey, Hull	262,271	3	2

Engineer's estimate, £98,736 5s. 6d.
*Recommended for acceptance on account of favourable conditions *re* time for completion.

The tender of J. G. White and Co. for the reconstruction of the tramways from North-street, Wandsworth, *viâ* York-road, Battersea Park road, etc., to Westminster Bridge, together with the lines in Lambeth-road and Falcon-road, at £163,874. 11s. 2d., is also recommended for acceptance, with power to sublet to Anderston Foundry Co. the manufacture of castings, Hadfield Steel Foundry Co. and Lorain Steel Co. the supply of special work, and Associated Portland Cement Manufacturers Co. the supply of cement.

The Highways Committee have received the following tenders for the supply, delivery, and erection of one 5-ton and one 2½ ton overhead travelling crane at the New Cross car-shed:

Carrick and Ritchie, Edinburgh	£859	0	0
H. Morris and Bastert, Loughborough	881	13	7
J. Hitchen and Son, Halifax	915	0	0
	980	0	0

BUSINESS NOTES.

TRACTION.

Chester.—The Corporation have decided upon ½d. stages for workmen.

Ipswich.—Half fares up to 8 a.m. and return tickets are to be introduced.

Halifax.—The local Trades and Labour Council is conducting a compaign in favour of ½d. fares for children.

Maidstone.—The Urban District Council have decided to invest £2 000 out of profits as a reserve fund in connection with the light railway.

Newcastle.—At a meeting of the Corporation on Wednesday it was decided, after some discussion, to set aside the sum of £9,000 as the nucleus of a depreciation fund.

Rotherham.—The Tramway Committee propose that in future the tramways centre be at the top of High-street instead of at College-square, and that an estimate of the cost of the additional lines be prepared.

Keighley.—The Corporation have referred back to committee a proposal that a charge of 1d. be made for "bulky parcels," a councillor expressing the opinion that confusion would ensue as to the definition of the term.

Belfast.—Although a considerable distance of track remains to be reconstructed, it is expected that the entire work will be completed next month. A deputation is to wait upon the Corporation in favour of ½d. fares.

Bournemouth.—After a lengthy discussion the Corporation decided against Sunday trams in the borough, although they already run over the Poole section. Even a suggestion for a half-day service did not meet with approval.

Damascus.—A combined electric lighting and tramway system is stated to be under serious consideration. The possibilities of this enterprise have been studied on the spot by a competent Belgian engineer, whose report is on the whole distinctly favourable.

Hastings.—The tramway service was inaugurated at 7.30 a.m. on Monday, a special car having previously made a satisfactory trial trip. On the first day 18 792 passengers were carried, the receipts amounting to £145, and on the subsequent days the traffic appeared to be, if anything, larger.

Falkland.—The Light Railway Commissioners have reported favourably upon a line three miles in extent for this district. The passenger traffic was estimated at 40 000 persons, and the goods traffic at 19,000 tons, exclusive of agricultural traffic. The cost was estimated at £18,500. The North British Railway Co. and a landowner opposed.

Croydon.—A start has been made with an extension of the tramway system which will bring it nearer to London. The line to South Norwood is to be carried through Anerley to two of the principal entrances of the Crystal Palace. On the completion of this work the system will extend from the Crystal Palace to West Croydon, and from Norbury to Purley, serving a very wide radius. A further extension to Mitcham is about to be commenced.

Derby.—The extension of the tramway service along the Duffield and Kedleston-road route was opened on Monday afternoon. A special car met Lieut.-Colonel Druitt, of the Board of Trade, at the Midland Railway Station. The car ran with the greatest of ease and comfort, and at 5.30 the first public car along the Irongate to the Kedleston-road made its initial journey, the vehicle being crowded. Six new cars are to be purchased at an estimated cost of £3,756.

Liverpool.—At Wednesday's meeting of the Corporation the following recommendation of the Tramways Committee was adopted: "That the sum of £75 000, being the cost of the purchase of the site of the new tramway offices, Hatton-garden, and the erection of the buildings thereon, be defrayed out of the reserve, renewal, and depreciation fund of the tramways undertaking for the present, and that the question of borrowing the amount under the sanction of the Board of Trade be postponed."

Southampton.—At the meeting of the Town Council a letter was read from the Bitterne Park and District Progressive Association appealing to the Council to apply for powers to continue the trams from Northam toll-gate to Bitterne Park terminus in order to complete the circular route. The matter was referred to the Tramways Committee. The manager recommends that in the reconstruction of the tramlines in Above Bar-street rock asphalt should be used instead of wood blocks on the score of durability and cheapness.

Accident.—Much excitement was caused at Ramsgate yesterday by the spectacle of an electric tramcar descending rapidly the Madeira-road, a sharp descent leading from the East Cliff to the harbour. The car in turning a corner left the rails, and then, knocking down a fence skirting the cliff toppled over and fell into a yard below, a distance of at least 40ft. The passengers were very few, and miraculously escaped serious injury, some of them jumping off the car. The driver went over the cliff with the car and was terribly hurt.—*Westminster Gazette.*

Parliamentary Bills.—The Lords' amendments have been considered and agreed to by the Commons in the case of the following Bills: Great Northern, Piccadilly, and Brompton Railway (No. 1) Bill; Shropshire, Worcestershire, and Staffordshire Electric Power Bill; Baker-street and Waterloo Railway Bill; Charing Cross, Euston, and Hampstead Railway Bill; Edgware and Hampstead Railway Bill; London and North-Western Railway Bill; Metropolitan Electric Tramways Bill; and the Dublin United Tramways Bill. The South Lancashire Tramways Bill has been read a third time in the Commons.

Wallasey.—The third annual report of the Council's tramways shows working expenses, £13,886. 11s. 2d.; receipts, £38,168. 3s. 5d. The passengers carried numbered 7,142,881, being an increase over the previous year of 569 952, representing an additional £2,903. The total number of miles run by all cars was 778,851, as compared with 757,688 for last year, an increase of 21,163, or 2·7 per cent. Twenty-six of the cars have had top covers fitted, and the remaining four are being similarly dealt with in accordance with resolution of the committee. The rolling-stock and general equipment of the undertaking have been maintained in good condition.

Dundee.—A *plébiscite* was expected to be taken yesterday on the question of Sunday running. The estimates for the current year make provision for an expenditure of £45,020, which is £384 in excess of the allocation for last year. The working expenses are stated at £27,800, some £79 over what was actually paid and £930 more than what was estimated for last year. The wages bill remains stationary. On the revenue side it is computed that the traffic receipts will total £44,350, which is £303 over what was actually earned during the year ending Whitsunday and £808 more than was estimated for last year. The estimates show a probable surplus on the year's working of £62, apparently without any allowance for Sunday running.

Lancashire and Yorkshire Railway.—The report for the half-year ended June 30 last states that the revenue account shows receipts from passengers, parcels, and mails £1,075 052, an increase of £22,110. Working expenses amounted to £1,523,193, an increase of £34,526. The net revenue balance available for distribution is £798,318, as compared with £760 394 in the corresponding half-year. The balance of net revenue account, after meeting the charge for interest on guaranteed and preference stocks, amounts to £319,351, which is available for dividend on the ordinary stock, and the directors recommend a dividend at the rate of 3½ per cent. per annum, carrying forward £20,504, as against 3 per cent. per annum for the corresponding period with a balance forward of £19,395.

Colchester.—The Corporation have adopted the following recommendation of the Tramway Committee: (1) To rescind its decision arrived on May 3 last relative to the price of such current supplied during the said eight months, and in respect of the supply for the financial year ending March 31, 1906; (2) to fix the price of current so supplied during the said eight months at 1½d. per unit; and (3) to

Digitized by Google

direct that the question of price for the financial year ending March 31, 1906, be considered by the joint committees previously to the completion of the next annual accounts of the electric light and power department, the tramways department in the meantime to pay on account for current at the same rate—viz., 1½d. per unit—the peyment to be subject to any needful adjustment after conference.

East Ham.—The Tramways Committee have reported that they had considered a letter from the Barking Council stating that they were prepared to grant a lease of their tramway track from the eastern boundary of the borough to Ripple-road for seven years, subject to the same being cancelled in the event of any extension being made. The committee recommended that the following clause be inserted in the agreement: "That the lease shall be for a fixed period of seven years, and that if in the meantime the portion of the proposed tramway track between Ripple-road and Fanshawe-avenue is constructed, the Corporation should be allowed to run over this length also, upon terms to be agreed, and that, failing agreement, the matter to be referred to arbitration." The Corporation have confirmed this.

Aberdare.—A special meeting of the Urban District Council was held last week to consider the report of the Parliamentary Committee and to receive the bill of costs for the promotion of the Tramway Bill. At the last ordinary meeting strong objections were taken to certain items in the bill. After some discussion, the report of the Parliamentary Committee was read, and sums amounting to £314 7s. for witnesses, £500 for counsel fees, £280 for engineers, and £224. 18s. out-of-pocket expenses to the surveyor, were recommended for payment, together with a sum of 200 guineas as a gratuity to the surveyor for extra work. The chairman of the Parliamentary Committee recommended the adoption of the report. Ultimately, the voting resulted in a tie, the chairman giving his casting vote in favour of the report.

Proposed Light Railway.—An inquiry has been held by the Light Railway Commissioners into the application of the Ryhope, Murton, and Hetton Syndicate for a provisional order authorising the construction of a light railway between Ryhope, Seaham, Murton, and South Hetton, joining the Sunderland and District Tramways Co.'s system at Ryhope and South Hetton. The original scheme was slightly altered, in that, owing to opposition on the part of the North-Eastern Railway Co. and the Marquess of Londonderry, that portion of the system between Ryhope and Seaham Harbour has been dropped. All the local bodies were in favour of the scheme. Colonel Boughey, the chairman of the Commissioners, said the evidence showed a considerable population round Hetton, Easington Lane, Murton, and Haswell which required access to Seaham.

Signalling.—The British Miller Signal Syndicate calls attention in a letter to the various railways to the Liverpool Southport disaster as another proof that the railway signalling system in this country is sadly defective. The letter states: "We have again and again called your attention to the wisdom—may we not say the necessity—of repeating the signal to the engine-driver in the cab of his locomotive where he can always see it. Further, and with special reference to Thursday's accident, the Miller system of signalling intimates to the driver, automatically, if the line ahead is blocked by another train, so that the signalman's mistake is promptly checked by the warning red light full on the driver's eye within the cab of the locomotive. The Belgians are busy installing this life and property saving system, the Americans are extending it, the French are examining it. Has not the time come for England?"

North-East London Railway.—A committee of the House of Lords, presided over by Lord Ludlow, commenced on Wednesday the consideration of the North-East London Railway Bill, which has passed the House of Commons. The Bill is opposed by the Great Eastern Railway Co. and by the trustees of the late Mr. E. Jones in respect of property in the City. The London County Council and the promoters of the Hammersmith, City, and North-East Suburban Railway, who opposed the Bill in the House of Commons, presented petitions "against alterations." The Bill proposes to incorporate a company, with a capital of four millions sterling, for the purpose of constructing an electric railway, partly underground, from the Monument to Waltham Abbey. Mr. Balfour Browne, K.C., having opened the case for the promoters, Mr. Courtenay Warner, M.P., repeated the evidence he gave in favour of the Bill before the House of Commons Committee, and the further consideration of the Bill was adjourned.

London United Tramways.—A complaint was made at a meeting of the Kingston Town Council as to the company's delay in completing the construction of lines. The Chairman of the Highways Committee replied that he did not think the position warranted the Council in taking legal proceedings at present. The Highways Committee recommended that the plan submitted by the company for the widening in Eden-street be approved, and that the plan for a double line of rails instead of a single line at the corner of Surbiton-crescent be approved, subject to the company making the necessary widening at the corner property. This was agreed to. The employés of the company held their annual sports at Brentford last Saturday, when several of the competitors distinguished themselves in the various events. Sir Clifton and Lady Robinson attended during the afternoon, and met with an enthusiastic reception. The Highways Committee of the London County Council recommend that the Council agree to the company's proposal for an alternative route of mains from Chelsea to Kingston, the idea being to select less busy thoroughfares.

Beckenham.—The draft agreement with the British Electric Traction Co. for the cancellation of the tramway agreement was submitted to a committee of the Urban District Council, and with the exception of some verbal alterations, which the committee recommend should be left to the solicitor to settle, the draft was approved and is recommended to the Council for acceptance. Points not previously agreed by the parties, but now included in the agreement, are as follows: (1) As to the costs of the Bill. Towards these costs the traction company agree to pay £4,000 by ten annual instalments, with interest. (2) Current for Penge tramways. The company do not propose to carry out the whole of the tramways authorised by the Croydon and District Electric Tramways Act, 1902, but they undertake that Beckenham shall supply the whole of the current for such tramways as they do construct, and guarantee a minimum consumption of 240,000 units per annum. (3) Term of contract for the supply of current for tramways. The company offer a contract for seven years at least, the price, etc., to be revised every five years.

Electric Tramway Concessions.—The *Gaceta de Madrid* contains a notice inviting tenders, which will be opened at noon on Sept. 20 at the Directorate General of Public Works, Madrid, for the concession of an electric tramway in Zaragoza. An application for this concession has already been made by the Zaragoza Tramways Co., who, at the same rates, will enjoy certain preferential rights over other tenderers. The competition will turn, in the first place, on the reduction of the tariffs proposed, and if two or more identical propositions are made, a further competition will take place verbally as to what reduction (if any) of the period (60 years) of the concession tenderers may be prepared to accept. A deposit of £14 is required to qualify any tender. The same issue of the *Gaceta* announces that an application, accompanied by a plan and guarantee, has been received at the Directorate-General of Public Works, Madrid, from the Malaga Tramways Co. for a concession for an electric tramway in Malaga. One month from the date of the publication of this announcement in the *Gaceta* (July 17) is allowed for the presentation of applications, accompanied by their corresponding plans and guarantees, upon terms more favourable to the Government.

Glasgow.—The report for the year ending May 31 states that the income amounted to £764,790. 16s. 8d., and the working expenses to £387,167. 9s. 2d., leaving a gross balance of £377,623. 7s. 6d. The income of the previous year was £723,190. 11s. 7d., and the working expenses £355 919. 5s. 5d., leaving a gross balance of £367,271. 6s. 2d. This year's gross balance thus shows an increase of £10,352. 1s. 4d. The gross balance of £377,623. 7s. 6d. has been applied in meeting rental of Govan and Ibrox tramways, payment to Paisley District Tramways Co., interest on capital, sinking fund, income tax, depreciation and permanent-way renewals, parliamentary expenses, and annual payment to the common good, these payments amounting in all to £287,437. 19s. The net balance remaining amounts to £93,298. 13s. 6d., of which £68,500 has been applied in meeting special depreciation on buildings, ducts, cables, overhead equipment, and power station and sub-stations plant, the balance of £24,798. 13s. 6d. being added to general reserve fund. It is pointed out that, although the gross revenue for the past year shows an increase of £41,600. 5s. 1d. over that of the previous year, the average traffic revenue per car mile has decreased from 10·58d. to 10·12d. This decrease is chiefly due to the augmented service of cars which is now given on all routes. Allowances are made for depreciation and renewals under a number of heads.

Birkenhead.—Mr. W. Wyld, general manager of the Corporation tramways department, states in his fourth annual report that although the income showed a decrease on the previous year of £1,047. 15s. 8d., and they had also had to meet an increased expenditure of £757 on interest and sinking fund account, yet they were, by reason of the saving effected in operating expenses, able to show a larger net profit on the year's working than last year. As the year progressed it was seen that the receipts were much below expectations on account of industrial depression, and it was realised that a surplus on the year's working could only be shown by exercising the most rigid economy in regard to operating expenses. There was a saving in the traffic and management expenses of £1,546. 1s. 10d., and a saving in cost of generation of electrical power and upkeep of overhead line work of £971. 13s. 2d., making a total decrease on those two items of £2,517. 15s.; but the expenditure on repairs and upkeep of permanent way continued to increase, showing an increase for last year of £617. 9s. 3d., bringing down the total saving in costs for the year to £1,900. 5s. 9d. That the decrease in receipts was without doubt due almost entirely to the bad condition of trade was shown by the fact that there was a decrease on the year of £925. 13s. 10d. for traffic along the docks route. That was more than the total decrease in the traffic receipts on the whole system. The total income amounted to £55,025, against £56,073 last year. The New Ferry route showed a decrease in profit of £690, this being due to the increased mileage it had been necessary to run. From July, 1904, to March, 1905, 26,000 1d. and 6,000 ½d. prepaid tickets had been disposed of, representing an income of £120. 16s. 8d.

Electrification in the States.—The New York *Times* states that contracts for electrical power recently let by the New York Central Railway suggest that the Vanderbilt syndicate is preparing the way for the development of electric lines along its system. The amount of electric power already contracted for suggests the possibility that something more is in contemplation than the operation by electricity of tributary lines. Among the contracts that the New York Central has already entered into for electrical power is one with the Ontario Power Co. for all the electrical power that the New York Central requires for the operation of its traction lines from Syracuse west to Buffalo. Another contract has been made with the Hudson River Electric Power Co., under which 4,500 h.p. is now being delivered to the Central lines in Utica, and which in its entirety calls for the increase of this power up to 25,000 h.p. as it may be needed. Plans are now under way for the electrification of the main line of the West Shore Road between Utica and Syracuse, and while this is directly connected with the development of the auxiliary trolley system, it appears to open the way to a still wider application of electrical power to the operation of parts of the Central system. The company's own

Digitized by Google

power house at Yonkers, under construction in connection with the terminal improvements now in progress at the Grand Central Station and northward, will probably be the nucleus of the first stage of the main line's electrification, and other sections are likely to follow. The general indications suggest, in fact, that the electrification of main lines is not such an impracticable step as was supposed until lately. In pursuance of its plan for the extension of auxiliary electric traction lines the New York Central management some time since created a special department for the direction of these lines. William K. Vanderbilt, jun., is now in charge of this department.

Railway Companies and Motor Omnibuses.—Lord Kintore's Select Committee of the House of Lords last week considered the North-Eastern Railway Bill, one of the principal objects of which is to authorise the company "to provide, own, work, and use in any district or to or from any place situate upon railways owned or worked by the company, not including railways over which the company have running powers, omnibuses, coaches, cars, and other road vehicles to be drawn or moved by animal, electrical, or any mechanical power" for the conveyance of passengers, luggage, parcels, merchandise, and goods. A committee of the House of Commons sanctioned the clause embodying this proposal, but imposed upon it modifications providing that the local authority might from time to time prescribe the route to be taken by these omnibuses between the points of arrival and departure, and prohibiting the running of any such omnibus "otherwise than to or from a station or hotel of the company, without the consent in writing of the local authority," with an appeal to the Board of Trade if the company considered themselves aggrieved by any decision or refusal of consent of a local authority. It was in this amended form that the company asked the Lords' Committee to sanction the clause. Sir George Gibb, general manager of the North-Eastern Railway, gave evidence in support of the clause, and stated that there was a considerable public demand for the service proposed to be rendered by means of motor omnibuses. Mr. Lloyd, addressing the committee on behalf of both the opposing corporations, admitted that there were many districts in which it might be, and probably would be, a great convenience to the public for railway companies to run a service of motor omnibuses, but contended that, in the special circumstances of Newcastle and Hull, there was no necessity whatever for including them within the purview of the clause. Evidence having been called in support of this view, the committee passed the clause. The Bill was subsequently ordered to be reported to the House for third reading.

Edinburgh and Dalkeith.—An inquiry was held last week into the provisional order asked by the Edinburgh Suburban Electric Tramways for a system between Edinburgh, from Liberton, and Dalkeith and Bonnyrigg. Mr. Wilson, K.C., in stating the case for the promoters, said the scheme was one urgently demanded by the neighbourhood, and it was looked upon with favour by all the local authorities interested. The district was an admirable situation for fening, there was a good supply of water, and the inhabitants with one voice were asking for the scheme. The line would commence from Liberton and go to Eskbank, where it would branch off to Dalkeith and Newtongrange, and in the other direction to Bonnyrigg and Broomieknowe to the borders of Lasswade. There was no real opposition, with one exception. The usual opposition was being offered by the railway company, but the Mid-Lothian County Council, Dalkeith Burgh, and Bonnyrigg were all in favour of the scheme. The promoters had entered into agreements with Dalkeith and Bonnyrigg to provide workmen's cars in the morning. The total length of the line would be practically seven miles, and, at a moderate estimate, the population served would be 39,800, while passengers would be able to travel much more cheaply than by rail. The gross receipts for the first year were estimated at £14,514, and the working expenses £10,160, leaving a surplus of £4,354. The capital of the company would be £25,000. The promoters asked for power to carry goods, subject to the consent of the local authorities. After hearing evidence, the preamble was held to be proven. The following day clauses were adjusted. Opposition was offered by the North British Railway Company and Colonel Gilmour to the clause authorising the carriage of animals, goods, and minerals on the tramway. It was argued by Mr. Cooper, K.C., for the former, that such powers were never granted in Scotland, the only exception being that of the Wemyss tramway, the circumstances of which were peculiar. He suggested that the authority should be limited to parcels of 56lb. Mr. Stephen Sellon, C.E., London, spoke of the practice in England and on the Continent and in America, where the carriage of parcels had proved an immense advantage. The Commissioners intimated that they granted the full powers sought in the matter of goods. Certain protective clauses were adjusted, and words were added leaving the promoters liberty to apply for an electric lighting order at a future date.

London County Council.—At the meeting of the County Council on Tuesday the tramways accounts for the year ended March 31 last were subjected to some criticism by Mr. Gaskell, who complained that there was a great deal of dead capital. Meeting these criticisms, Mr. J. Allen Baker, M.P., chairman of the Highways Committee, said that during the period in which the lines in the South of London had been operated by the Council £208,000 had been paid out of revenue in reduction of capital. He contended that the accounts were on a sound financial basis. The Council agreed to a capital expenditure of £59,394 in respect of the equipment of the tramways from the Strand to Theobald's-road and the Highways Committee was authorised to make arrangements with the North Metropolitan Tramways Co. for the electric working as a through route of the subway tramways and the tramways between Theobald's-road and Islington. The Parliamentary Committee, reporting upon the rejection of the Council's Tramways Bill by the House of Lords, spoke of the "high-handed policy of the House of Lords," and expressed the opinion that "there is great reason for the public to resent the action of a majority of the Upper House in using parliamentary powers which should only be exercised for the benefit of the public, to support individual views and interests." The report was approved, and it was decided to revive the proposals included in the Bill in the next session of Parliament, and to invite the City Corporation to introduce a Bill for the widening of Blackfriars Bridge or the construction of a new bridge. After the summer vacation the Highways Committee will submit plans for new tramways costing £414,160, and involving a further sum of £209,034 in widening streets. The largest item in these proposals is the sum of £190,200 for a line from the Marble Arch to Cricklewood. The Highways Committee propose that the car-shed at Wandsworth be reconstructed at a cost of £36,810, the work to be executed by the Council. It has been decided that the eyesight of all motormen shall be tested so as to minimise risk of accidents. Out of 340 men, 40 were found to have defective sight, but other employment has been found for them. The committee recommended that an agreement be entered into with the County of London Electric Supply Co. for a temporary supply of power at 1d. per unit to operate the tramway subway and the route between the Strand and Islington, the Council undertaking to take at least 500,000 units per annum. It is proposed to expend £12,000 upon single-deck cars for the line from the Strand to Islington.

LIGHTING AND GENERAL.

Long Eaton.—The Urban District Council are raising £3,500 for works of electric lighting.

Cannock.—The Council's application to borrow £13,000 for electric lighting purposes has been granted.

Sales of Land, etc.—Particulars of various sales of land and business sites appear in another column.

Greenock.—The Electricity Department's financial statement for the year ended June 30 last shows a surplus of £1,600.

Poplar.—On Saturday last the employés of the Poplar electricity works took their outing by brake to the Red Lion Hotel, St. Margaret's.

Kingston.—The Lighting Committee have taken active measures to oppose the Administrative County of London and District Electric Power Co.'s Bill.

Grimsby.—The Electric Lighting Committee have handed the Council £890, profits of the electricity undertaking for the year, for the relief of the rates.

Stafford.—An increase of 63 per cent. in the output of electricity compared with corresponding period last year was reported at the last Town Council meeting.

Dunstable.—The National Provincial Electricity Corporation intend to apply for a provisional order to empower them to supply electricity for all purposes within the borough.

Aberdeen.—During the month of July there were generated at the electricity works 291,459 units, as compared with 290,722 in the corresponding period of the previous year.

Wellingborough.—A proposal made by the County of Northampton Electric Power Co. with respect to lighting and destructor has been referred to Mr. Bakewell for his observations and advice.

Court of Common Council.—At the last meeting of the Corporation a letter from the City of London Electric Lighting Co. (which we publish in another column) was read and referred to the Streets Committee.

Cardiff.—The National Telephone Co. have installed instruments for call office purposes in a number of Corporation cab shelters. A fee of 2½. is charged for all communication to subscribers connected to the Barry exchange.

Stirling.—The Water Commissioners have agreed to purchase from a Newcastle firm, at a cost of £500, an engine and electric motor for the purpose of pumping into the mains the water from St. Ninians Well in the Craigs.

Calcutta Electric Supply Corporation.—The number of units delivered to consumers during the five weeks ending June 30, 1905, were 550,733, compared with 383,457 in the corresponding five weeks of the previous year.

New Issues.—The Urban Electric Supply Co. are issuing 20,000 5 per cent. cumulative preference shares of £5 each at par, and the Buenos Ayres Port and City Tramways are issuing £200,000 6 per cent. first debenture stock.

Watford.—The Uxbridge and District Electric Supply Co. intend to apply for a provisional order for the supply of electricity within the Rickmansworth rural district. The Rural District Council have declined to give their consent.

Brighton.—The Lighting Committee have decided to recommend the Town Council to apply for sanction to borrow £38,500 for works in connection with the electricity undertaking. The extension of the telephone system to Burgess Hill has been put in hand.

Kensington.—A notice from the Notting Hill Electric Lighting Co. relative to a proposed extension of their mains in Campden-hill-square, as well as applications of the General Post Office to lay pipes for telephone wires, has been agreed to under the usual conditions.

Sunderland.—The estimates of the Electricity and Lighting Committee for the half year ending March 31, 1906, are as follows: expenditure for electric lighting, £13,782; gross revenue, £29,439; as against £13,033 and £26,671 respectively in the corresponding half-year.

Metropolitan Electric Supply Bill.—The Metropolitan Electric Supply Co.'s (Various Powers) Bill has passed the Select Committee. Protective clauses have been inserted to guard against the company obtaining powers which they had transferred to the St. Marylebone Borough Council.

Digitized by Google

Lancaster.—It is proposed to reduce the price for lighting current from 5d. to 4½d. per unit, subject to the usual discount of 5 per cent. allowed by the Corporation on payment of accounts within 28 days from the date of delivery thereof, the reduction to take place after June meter readings.

Torquay.—Application is to be made for a loan of £8,500 for the electricity scheme, which includes the extension of the generating station referred to in our last issue. The borough electrical engineer (Mr. P. Storey) and the engineer of the Dolter Co. (Mr. E. A. Mitchell, M.I.E.E.) are conferring as to details.

Wimborne.—The Rural District Council have consented to an application of the Bournemouth and Poole Electricity Supply Company to erect standards on the sides of the roads, for overhead wires, in this Council's area, over which they are obtaining powers to supply in their Wimborne and district electric lighting order.

Swindon.—It has been resolved to extend the electric mains as far as the entrance to the isolation hospital at Gorse Hill. The last monthly report of the electrical engineer shows that the number of consumers connected on the 15th ult. was 354, as compared with 208 a year ago. The number of street lamps converted to date was 187, as against 138 a year ago.

Maidenhead.—Approximately, 2,000 units have been sold in the Maidenhead Court extension, which has only been supplied during a part of the quarter. It is a hopeful sign that for several weeks now there has been a considerable day load, and during the present week it has been necessary to run throughout the day. It is expected to secure several power users.

South Shields.—The Electrical Committee propose to rescind the present uniform charge of 2d. per unit for current for heating and lighting purposes and to adopt the following scale of charges for current for power purposes—namely: where the consumption does not exceed 150 units per quarter per each horse-power installed, 1½d. per unit; over 150 and less than 300 units, 1¼d.; over 300 units, 1d.

Faversham.—The accounts of the municipal electric lighting undertaking for the period from June 9, 1904—when the works were opened—up to March 31 last have just been published. The sum borrowed is £18,400, of which £15,771 has been expended. The revenue account shows receipts £862, and includes £532 put down for public lighting. Expenditure totalled £623, leaving a gross profit of £230.

Maidstone.—The accounts of the Urban District Council's electricity department show that at the end of three years' working there is a balance of £466 to the good after the payment of all charges, including principal and interest. The business is steadily increasing. The Council expect in the near future to do the pumping at the sewage works by electricity instead of steam. A reserve fund of £2,000 is to be created.

Railway Directory.—We have received from the Directory Publishing Co., 3, Ludgate-circus-buildings, London, the current issue of the "Universal Directory of Railway Officials," compiled from official sources under the direction of S. Richardson Blundstone. This work, which is published at a price of 7s. 6d. to subscribers and of 10s. after publication, covers the whole globe, and increases year by year in size and in usefulness.

Ripon.—At the last meeting of the City Council a letter was read from the Non-County Borough Association in London regarding the intention of the National Telephone Co. to apply to Parliament for certain powers, among them being the pulling up of the streets for the purpose of laying their wires without first obtaining the consent of the local authorities. The Council agreed to assist other councils by asking the member of Parliament for the division to oppose Clause 9 (5A) in the company's Bill in Parliament.

Derby.—The Electric Lighting Committee have decided to ask the members of Parliament for Derby to oppose the County of London and District Electric Power Bill and the Metropolitan Electric Supply (Various Powers) Bill, now before Parliament, as, in the opinion of the committee, these Bills contain proposals calculated to form precedents fraught with danger to the interests of local authorities throughout the country. The Town Council have granted the sum of £256 for wiring the market hall, butter market, and entrances for electric lighting purposes.

London Gazette.—The partnership between James Carter and John Horsfall, electrical engineers, 33, Manchester-road, Nelson, and motor and mechanical engineers at Holly Bank, Brierfield, Lancaster, has been dissolved by mutual consent. A receiving order has been made out on debtors' petition in the estate of John Weston Martin and John Primmer Poor, jun., electricians, 154, New-road, Buckland, Hants. A second and final dividend of 1s. 4d. in the £ has been declared in the estate of Charles Aubrey Smith, electrician, 23, King-street, Regent-street, London.

Bath.—The electricity department shows a net loss on the year's working of £131, but there has been paid during the current year £289 more in rates and taxes, £722 more to the sinking fund, and extra interest £1,052. The undertaking is making steady progress. From March to June last year 246,091 units were generated, but only 90,641 were sold. During the corresponding period this year 221,498 units were generated and 94,184 sold, showing that the department was losing very considerably less in distribution owing to the introduction of the continuous-current system.

"Wireless" Telegraphy on Railways.—The London, Brighton, and South Coast Railway Company have obtained a license to install a Rochefort wireless telegraphic service at Newhaven to communicate with their steamers and the French Western Railway Company's station at Dieppe. The Midland Railway Company have received sanction to institute a wireless telegraph service, worked on the Lodge-Muirhead principle, at Spondon, near Derby, to communicate with a movable railway van within a radius of 10 miles. This company have also applied to the Postmaster-General for permission to use wireless telegraphy between their new port, Heysham, and their steamers to Ireland and the Isle of Man.

Redditch.—The electricity works manager reported at the last District Council meeting that, compared with the previous 12 months, the progress made by the electric supply undertaking in the past 15 months had been very satisfactory. On Jan. 1, 1904, the total number of consumers was 236. On March 31, 1905, the number was 333. On Jan. 1, 1904, the total lamp connection in 8-c.p. lamps was 15,844; on March 31, 1905, it was 23,345. The gross profit on the 15 months' working was £783, an increase of £323 over that obtained in 1903, and equal to a dividend of 2½ per cent. on the capital expended at the beginning of 1904. The analysis of the works costs showed that in the past 15 months the total cost per unit had been reduced from 2·07d. to 1·67d.

Institution.—The *Journal* of the Institution of Electrical Engineers, Part 174, edited by G. C. Lloyd, secretary (Messrs. E. and F. N. Spon, Limited, 57, Haymarket, S.W.), contains "Stand-by Charges and Motor Load Development," with discussion (Birmingham Local Section) by A. M. Taylor; "Telephone Traffic," with discussion, by H. L. Webb; "Wireless Telegraphy Measurements," with discussion, by W. Duddell and J. E. Taylor; "Low-Tension Thermal Cut-Outs," with discussion (Manchester Local Section), by A. Schwartz and W. H. N. James; "Notes on Heating and Sparking Limits in Variable-Speed Motors," with discussion (Birmingham Local Section), by A. H. Bate; and "Commutation in a Four-Pole Motor," with discussion (Birmingham Local Section), by J. K. Catterson-Smith.

Stock Exchange.—The Stock Exchange Committee have appointed Aug. 15 special settling day for the Hastings and District Electric Tramways Co.'s £125 000 4½ per cent. debenture stock. The committee have also ordered the said securities and the Sunderland District Electric Tramways £160 000 5 per cent. first mortgage debentures of £100 each, Nos. 1 to 1,600, to be quoted in the official list. Applications have been made to the committee to appoint a special settling day in and to grant a quotation to Babcock and Wilcox's further issue of 270,000 ordinary shares of £1 each, Nos. 530,001 to 800,000. The committee have also been asked to appoint a special settling day in the Metropolitan Electric Tramways Co.'s 182,181 ordinary shares of £1 each, fully paid, Nos. 1 to 40,785 and 249 912 to 391,337; and to allow the Havana Electric Railway Co.'s 6,975 000dol. consolidated mortgage 5 per cent. 50-year coupon bonds of 1952 for 1,000 dol. each, Nos. 1 to 6,975, to be quoted in the official list.

Aston.—At the last Town Council meeting a statement was made as to the financial result of the working of the electricity undertaking for 18 months. The revenue account for the six months ended March 31, 1904, showed an adverse balance of £4,151, and the account for the 12 months ended March 31, 1905, showed a loss of £4,122. The latter account include £920 written off for depreciation of plant. The loss shown on last year's account was almost entirely incurred in the six months ended September, 1904. A comparison of the figures for the half-year ended March, 1904, and March, 1905, is most encouraging. Whilst the expenditure for the two periods in question remained practically equal the income increased from £1,680 to £6,050. The additional income was produced chiefly by the traction supply. The arc lamps cost £510 per year, and of this only £180 per year was refunded by the Public Works Committee, this involving a loss of £330. In the three months ended June 30, 1904, the Council sold for lighting purposes 25,654 units as against 49 991 in the same three months of this year, for power purposes 29,657 units against 55 575 units, and for traction purposes 85 510 units as against 215 920. In March of 1904 the number of 8-c.p. lamps connected was 11,952, which had gradually risen to 22,443 in June of this year. The total cost per kilowatt installed was £62.

Long Firm Frauds.—The *Daily Chronicle*, in an article on the recent frauds perpetrated on electrical firms, says £40,000 is the sum that is mentioned in connection with what are alleged to be a most ingenious series of frauds that have been perpetrated on a number of electrical firms in the City. The following police notice circulated amongst jewellers and pawnbrokers supplies a key to the nature of the case: "Wanted, —— ——, 35 to 39; 5ft. 8 or 9; hair dark; moustache untrained. Rather long, angular face; swinging gait; slightly stooped. Two false teeth in front of upper jaw; plausible. For fraud." Then follows a list of notes which the "wanted" man is alleged to have in his possession. In order to carry their scheme into execution, the chief actor in the drama and his confederates adopted a *modus operandi* that was ingenious and amazingly daring. Taking premises in the City, they gave themselves a trade name, furnished their offices with all the sumptuousness of prosperity, and held themselves out as suppliers of all kinds of electrical fittings. With his hook thus baited, the moving spirit of the gang, faultlessly attired, would drive up to the warehouses of large electrical firms, saunter into the office, and place an almost impossible order, on account of its large size, for, say, lamps, mentioning just as impossible a time in which it was to be completed. The result was always the same. He would be informed that the order could not be executed. His next move was to suddenly remember that "his own establishment could easily turn out the lamps," and go out, leaving the individual whom he had seen impressed with its wonderful capacity. In this way the men managed to "rope in" a number of orders, along with large sums of money in notes and cheques, which, it is asserted, were exchanged for gold at the earliest opportunity. In a few weeks orders had come in to the tune of £40,000. Inquiries for orders were disposed of by means of all sorts of trade excuses, until several days ago one client, more enterprising than the rest, paid the wonderful electrical engineers a visit, and found that they had gone away. It was found that no fewer than 20 odd houses had suffered, some of them the largest in the trade. About 14 have decided to combine in a joint prosecution. The others have left the matter to run the ordinary course.

St. Pancras.—The gross revenue of the municipal electric undertaking during the year ended March 31 last amounted to £68,459, a decrease of £7,652 compared with the previous year. The decrease is attributed to reductions in the charge for current. There is a net profit on the year's working of £13,098. Of this it is proposed to devote £3,000 to the relief of the rates of the borough, £10,000 being added to the electricity reserve fund.

Eastbourne.—Mr. J. K. Brydges, the electrical engineer, has issued his annual report. Last year £750 went to the relief of the rates, and this year £725, or an equivalent of a ½d. rate. The number of consumers has increased from 794 in 1902-3 to 977, while the units sold have been advanced from 669,132 to 947,671. A sum of £2 000 has been placed to the depreciation fund as compared with £1,000 in each of the previous two years. The cost of working has also been reduced, the total cost per unit sold being 1·951d., as against 3·57d. when the Corporation acquired the undertaking.

Buxton.—The following estimates are under consideration: gas-engine, dynamos, and foundations, £900; 1,200 yards ·25 feeder, £520; 1,500 yards distributor, £525; 60 meters at £2. 7s. 6d. each, £142. 10s.; 60 demand indicators at £1. 11s. 6d. each, £94. 10s.; 60 consumers' fuse boxes at 13s. 6d. each, £40. 10s.; 900 yards ·035 service cables at 2s. 6d. per yard, £112. 10s.; 900 yards ·022 service cable at 2s. per yard, £90; 60 service boxes and fittings at 21s. each, £63; contingencies, buildings etc., £512; capital account overspent March 31, 1905 (998), say, £1,000—total, £4 000. A resolution to oppose clauses of the telephone agreement has been passed.

Islington.—The Borough Council have now decided that the present rates for the supply of electricity for power, heating, and cooking purposes be altered from 2d, 1½d., and 1¼d. to a uniform rate of 1d. per unit, subject to the consumer entering into an agreement with the Council to take such supply for a period of not less than three years, and that the existing time limit be abolished. The Council will to-night consider a report from the Lighting Committee as to price proposed to be charged to consumers of current of not less than 200,000 units per annum; recommending an expenditure of £2,000 in order to afford the supply of electricity required at the new post office buildings in Upper-street, estimated to be 250,000 units for lighting and 85,000 units for power per annum.

Holidays.—The New Palace Steamers Limited announce that their only alterations in sailings for Bank Holiday will be that the "Koh-i-noor" will leave Old Swan Pier (London Bridge) on Saturday, Aug. 5, at 8 a.m., for Margate, and on Sunday, Aug. 6, at 8.30 a.m., and on Monday, Aug. 7, at 8 a.m., for Southend, Margate, Ramsgate, Deal, and Dover, so as to relieve the likely large numbers on the "Royal Sovereign." The Husbands' Boat will be run on Saturday, Aug. 5, as usual. There will also be an additional sailing by the "Koh-i-noor" on Tuesday, the 8th, leaving Tilbury at 9.30 a.m., special train from Fenchurch-street at 8.27 a.m., St. Pancras at 8 a.m., for Southend and Margate, and intending passengers who wish to have further particulars are requested to write to the office of the company, 50, King William-street, E.C., where their communications will then be promptly attended to.

Beckenham.—The Electric Lighting and Tramway Committee in their last report on the arbitration proceedings with regard to the Crystal Palace district, stated that on the order of the arbitrator the claimants have now sent in a claim under three heads—mains and works at present existing in the district, £6,399; ditto formerly existing but now removed, £725; ditto situated outside the area but which the company claim have been necessarily provided for the service of the Crystal Palace district, £1,638—total, £8,762. The lengths and descriptions of mains and works in the district have been agreed between the engineers of the respective parties, and the officers of the Council have met the company's representatives to examine vouchers, but no separate account as required by the provisional order has been kept, and no vouchers appear to exist. The matter is expected to be before the arbitrator again before the vacation. The accounts of the electric lighting and dust-destructor undertakings for the year 1904-5 show a net loss to the contractors of £426 on the combined undertakings, but a profit of £364 in respect of the electric lighting undertaking.

Dundee.—A sub-committee is considering a report of the electrical engineer on the chance of cultivating a good shipyard load. The engineer says that he has been trying to negotiate with Messrs. Gourlay Bros. and Co., and had made them an offer based on the system of charging now extant for power in Dundee of 1·2d. per unit. They in their turn had offered to give the Council the whole of their power in the whole of their shipyard if not charged more than 1d. per unit, for an experiment for one year, after which time they would be willing to consider the revision of the rate should it not prove satisfactory. The engineer says it will depend entirely upon how far this class of business is developed whether it will pay at that price or not. In a big business of this sort in different shipyards, the maximum demand would be fairly low compared with other forms of load, such as the tramways, and the consumption of units in proportion would be much larger. On this ground there would be a chance of it paying. On the other hand, if they did supply about £1,000 worth of current for one year to Messrs. Gourlay, the loss on this for one year would not amount to a great deal, and would be undoubtedly valuable as an experiment.

Southwark.—The annual accounts of the electric light undertaking for the year ended March 31, 1905, show an ordinary income, after deducting £517 for discounts and allowances and £40 for bad debts, of £12,342, which is an increase of £141 on that of the previous year. To this is to be added £53 for pupil's premium and £17 for commission on sale of motors, bringing the total income for the year up to £12,413. The total working expenses amount to £7,576, being an increase of £297 on last year's expenditure. The gross profit on the year's working is £4,836, being less than that of the preceding year by £114. A special item of £235 has been placed to the credit of net revenue account this year, being the amount retained on settlement of the income tax assessment with the surveyor of taxes, making the total profit for the year £5,132. Against this profit has been charged £2,473 for interest on loans and overdraft, £2,197 for repayment of capital, and £79 instalment of the capital expenditure in excess of borrowing powers at the close of last year. The net profit for the year is, therefore, £382, which together with the balance standing to the credit of net revenue account at March 31, 1904—viz., £224—has been transferred to a reserve account in accordance with the Council's resolution of March 1, 1905.

Manchester.—The annual visit of the Electricity Committee to the generating stations took place on Thursday last week, when a statement was made by Mr. Alderman Bowes chairman of the Street Mains Sub-Committee, who said that there were now nearly 300 miles of main conductors laid in the town, exclusive of services, and that the present area of supply was 20 square miles, the total authorised area being 44 square miles. The sales of current during the year ended March last were as follows: for tramway purposes, nearly 19 million units; for lighting purposes, nearly 10 million units; for power purposes, nearly 4¾ million units; and for public lamps, 81,000 units—the total sales exceeding 33½ million units for the year. The committee had concluded an agreement with the Gorton District Council to take over the lighting of certain streets in Gorton. They would displace about 80 gas lamps, and put up in their stead 45 arc lamps, each of 400 c.p. The cost of the gas system was £6 per lamp per annum, which, reckoning 80 lamps, meant a yearly expenditure of £180. Under the electrical system the cost would be £8 per lamp, or £360 per year, and the illuminating power would be more than double that of the gas lamps. He expressed a strong desire that the City Council would allow the Electricity Committee to light Cheetham Hill-road. The cables were already laid, but they had been lying idle for years.

Poplar.—The Borough Council are taking up a loan of £10,818. The original application was for £12,140. The County Council have declined to sanction the following items: £980 for three spare armatures, and £342 for expenditure under the heading of "buildings" and "office furniture"—£1,322. The reason for the omission of the £980 is that the London County Council are advised that the provision of this duplicate machinery is more a nature of a renewal than spares, and, in accordance with the condition imposed by his Majesty's Treasury upon all borrowers on the 42 year term, the cost of all renewals must be provided otherwise than by loan. The committee consider that such items should be provided out of revenue balances in the same way as stores. The amount of £342 is eliminated because the items which go to make up this sum are for very trifling amounts, and should be defrayed out of revenue account. The revenue account for the quarter ending June 30 shows that the total increase was 128 074 units. There was a large increase in power—viz., 275,678—being an increase of 93 000 over the same quarter last year. This represents an increase of 50·55 per cent., and of 51 per cent. of the total output of the station. The private lighting has also increased by 27,889 units. The money value of the increase was approximately £500 for power and £1,071 on the whole output.

Wolverhampton.—The accounts of the electricity undertaking for the last year show a gross profit of £12,995, or 8·69 per cent. on the capital expenditure (averaged during the year). Out of this amount the following charges have to be met: Interest, £4,305. 2s. 6d., less interest received £104. 6s. 3d., £4,200. 16s. 3d. (2·81 per cent. on average capital); sinking fund and repayment of loans, £4,984. 11s. 2d. +£356. 8s. 10d., £5,341 (3·57 per cent.); balance, being net profit for the year, £3,454 1s. 10d. (2 31 per cent.)—total, £12,995. 18s. 1d. (8 69 per cent.). The committee consider that this result is especially gratifying when it is remembered that very substantial reductions have been made in the price of current for lighting and motive power purposes during the period covered by these accounts, and that a large reduction has also been made in respect of the charges for public street-lighting, the actual diminution in revenue from these causes being about £3,700. There was a continuous diminution in the cost of production, the expenditure on the generation and distribution of electricity—inclusive of all management charges, but exclusive of capital charges—being actually less for the year ended March 31, 1905, than it was for the preceding 12 months, although the output of electricity has increased by 33·3 per cent. During the past year the output of electrical energy to private consumers for lighting and motive power has increased by 11 per cent., and the committee have every reason to believe that this rate of increase will be considerably exceeded during the present year's working. The committee conclude by saying there is a slight improvement in the percentage of electricity sold to electricity generated, the figure of 83·24 per cent. being exceptionally high, representing a standard that it will be somewhat difficult to maintain.

London County Council.—On Tuesday tenders (*a*) for the manufacture, supply, and delivery of double-deck tramcar bodies with roof covers; (*b*) for the manufacture, supply, and delivery of maximum traction swing bolster trucks for electric tramcars; (*c*) for the manufacture, supply, and delivery of electrical equipments for tramcars were referred to committees. It was agreed to lend the Battersea Borough Council £1,934 for street-lighting; the Hackney Borough Council £21,708 for electric lighting and street-lighting extensions; the Hampstead Borough Council £5,100 for electricity meters and £5,000 for housing purposes; the Marylebone Borough Council £150,000 for electric lighting purposes; and the Stoke Newington Borough Council £3,000 for electric lighting purposes. Sanction was also given to the Stoke Newington Borough Council to borrow £13,750 towards the cost of the installation of electric light in the borough. The Highways Committee recommended (*a*) that, subject to the approval of the estimate of £59,394, submitted by the Finance Committee for the equipment of the through tramways route between the Strand and the Angel, Islington, expenditure on capital account not

Digitized by Google

exceeding £5,024 be sanctioned in connection with the laying of cable ducts, and the supply of electrical plant and cables required in connection with such work; (b) that the operation of Standing Order No. 23, which requires that all tenders where the expenditure exceeds £500 shall be opened in the Council by the chairman, be suspended, so far as regards the tenders for the several works referred to the foregoing resolution; that the Highways Committee be authorised to arrange for the invitation of tenders either by advertisement or from selected firms for the works in question; that the chairman or the vice-chairman of the Highways Committee be authorised, during the summer vacation, to open any tenders that may be received, and to accept the one in each case which appears to be the most satisfactory.

Croydon.—The annual report of the borough electrical engineer, Mr. Alex. C. Cramb, shows that the gross profit for the year was £24,683, as compared with £21,058 for the previous year, from which (after deducting interest and sinking fund and carrying forward £76 to the next account) a net profit of £6,332 was left. In addition to this amount paid for out of this year's revenue were the following items: conversion to triple expansion of No. 5 engine, £277; building etc., sub-station "H," £221; an amount written off in respect of old rectifiers of £556; cost of issue of debentures, charged to revenue, £1,015—total, £2,071. The first item has resulted in greatly increasing the efficiency of the engine. With regard to the second item, although a small temporary sub-station previously existed close to the site on which the new one is built, the present expenditure has been for a sub-station of capacity to meet all future requirements. The revenue account had been further reduced by about £861, due to reduced charges made to consumers. The capital expenditure during the year amounted to £12,288 on mains, etc., and £22,027 on building and plant, etc., bringing the total capital expenditure for the undertaking to £305,574. The total expenses for the year to £24,992, as compared with £25,538. The generation wages have increased by £494, due to a more liberal scale of payment. The amount paid for coal has been reduced by £417. Stores have been reduced by a sum of £486, and repairs by £482. The distribution salaries were lower by £145, and the repairs have been reduced by £119. With the exception of a small increase in salaries for generation, and a rather heavy increase in wages for both generation and distribution, there has been an actual reduction in the amount paid for all the other items, although 284,689 units more have been sold this year than for the previous one. There was an increase of £344 for rates, and this on top of a very heavy increase under this heading over last year's account. There has been an actual reduction of £71 in general establishment charges. The total expenditure is £566 less than last year, and the total cost, irrespective of interest and sinking fund charges, has been reduced from 1·589d. to 1·444d. per unit, being a reduction of ·145d., which may be taken as a satisfactory result. If it had not been for the rather heavy increase in wages and rates, the result would have been even more satisfactory. The revenue for the year was as follows: year ending March, 1905—private lighting, £28,128. 16s. 11d.; public lighting, £7,627; trams, £13,109; other sources, £809—total, £49,675. The revenue is higher than last year by £3,079. The number of consumers to March, 1904, was 1,721, and to March, 1905, 2,061, showing an increase during the present year of 340. The output from the works is given as follows: units sold, public lighting, year ending March, 1905, 692,485, year ending March, 1904, 656 905, traction 1,573,098 (1,475,656), private consumers 1,652 354 (1,500,687)—total sold, 3,917,937 (3,633,248); used on works, 418,739 (447,780); lost in distribution and used for experimental and testing purposes, etc., 505,398 (382,315); total units generated, 4,842,074 (4,463,343). The percentage of units sold to units generated was 80 9. For preceding year the percentage was 81·4. The committee consider that the amount of plant installed for tramway and direct current supply hardly leaves a sufficient margin for breakdowns. They also say that the greatest obstacle at the present time in obtaining private house consumers is the question of the cost of installation. They had lost the supply of electric light to several hundred houses during the last year owing to the fact that they were unable, in any way, to facilitate the fitting up of the same, and as in many cases the houses were not owned by the occupiers and were held on short leases, it was not to be expected that many persons, however desirous they might be of having electric light, would go to the expense of fitting up other people's houses.

PROVISIONAL PATENTS, 1905.

JULY 24.

15196. **Improvements in systems of telephony.** The British Thomson-Houston Company, Limited, 83, Cannon street, London. (The General Electric Company, United States.)

15266. **Improved construction of electrical resistance apparatus.** Ernest Haertel and Aage Jensen, 173, Fleet-street, London.

JULY 25.

15222. **Improvements in fuse heads for electric blasting.** Frederick Render, 6, Bank-street, Manchester.

15252. **Improved means for operating switches employed in electric traction on the surface-contact system.** Robert Brown, 16, Great George-street, Westminster, London.

15253. **Improvements in switches employed in electric traction on the surface-contact system.** Robert Brown, 16, Great George-street, Westminster, London.

15254. **Improvements in switches for electric traction on the surface-contact system.** Robert Brown, 16, Great George-street, Westminster, London.

15257. **Storage batteries.** William Gardiner and Cornelius Pruyn Stringfield, 65, Chancery-lane, London. (Complete specification.)

15265. **Improvements in electromagnetic vibrators.** Ragnar Carlstedt, 111, Hatton-garden, London. (Complete specification.)

15289. **Improvements in and relating to telephone call registers.** August Meyer, 77, Chancery-lane, London. (Complete specification.)

15290. **Transportable telephone apparatus.** Nicolay Jacobsen, 77, Chancery-lane, London. (Date applied for under Patents Act, 1901, Dec. 16, 1904, being date of application in Norway.) (Complete specification.)

15298. **Improvements in multiple telegraphy.** Sterns Francis Jones, 322, High Holborn, London. (Complete specification.)

15299. **Improvements in multiple telegraphy.** Sterns Francis Jones, 322, High Holborn, London. (Complete specification.)

15301. **Improvements in signalling devices or telegraphs.** De Courcy Beamish, 6, Lord-street, Liverpool.

JULY 26.

15345. **Improvements in electric lifts with electromagnetic control.** Charles George Major, Edwin Charles Stevens, and Percy Herbert Stevens, "Janus" Works, Queen's-road, Battersea, London.

15380. **An improved process for the electrolytic manufacture of metallic wire or strip.** Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

15381. **Improvements in the electrolytic production of metallic strip.** Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

15390. **Improvements in the manufacture of electrical resistances.** Charles Ruzicka, Clun House, Surrey-street, Strand London.

JULY 27.

15397. **An improved electrical signalling apparatus for electric lights or lamps.** Maxwell Telford, Thomas Grier, and George Finlayson Mackay, 82, Gordon-street, Glasgow.

15435. **Improvements in and connected with the employment of telephone meters in common microphone battery system.** Hermann Oppenheimer, 55, Redcross-street, Barbican, London. (Aktiengesselschaft Mix und Genest, Germany.)

15460. **Improved means of keeping constant the voltage of a dynamo-electric machine under variations of speed and current output.** Matthew William Walbank Mackie, 173, Fleet-street, London.

15462. **Improvements in the process of making a metallic connection between the light-emitting bodies and the supply conductors of electric glow lamps.** Hans Kuzel, 322, High Holborn, London.

15464. **Improvements in and relating to electric switches.** John Ward Cook, Cobden-buildings, 67A, Corporation-street, Birmingham.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Aug. 17.

1904.

16038. **Telephone system.** Brander.

16059. **Apparatus for the generation of electricity primarily designed for the electric lighting of trains.** Hutchins.

16210. **Electrical winding mechanism and switches connected therewith.** Du Bois.

16255. **Systems of electrical distribution.** Weintraub. (Date applied for under International Convention, July 23, 1903.)

16257. **Operating electric rectifiers, vapour lamps, and the like in systems of electrical distribution.** Weintraub. (Date applied for under International Convention, July 23, 1903.)

16815. **Armature connection for motor electricity meters** Geyer.

17018. **Electro-pneumatic control systems.** British Thomson-Houston Company, Limited. (General Electric Company.)

17862. **Electrical conductors specially applicable to overhead conductors for electrical tramways.** Ginders.

18202. **Electric motor control and apparatus therefor.** British Thomson-Houston Company, Limited. (General Electric Company.)

18356. **Electrolysers.** Bartelt.

19109. **Single-phase commutator motors.** Punga.

19540. **Combined rail and road electric tramway system and vehicles therefor.** Dixon and Dixon.

20380. **Electric arc lamps,** Carolan. (General Electric Company.)

20381. **Rectifying alternating electric currents.** Carolan. (General Electric Company.)

20473. **Electric transforming devices.** Carolan. (General Electric Company.)

20548. **Automatic electromagnetic controllers, especially applicable for use in electric metering systems.** British Thomson-Houston Company, Limited. (General Electric Company.)

20550. **Control of electric motors.** Carolan. (General Electric Company.)

Digitized by Google

20809. Electric furnaces. British Thomson-Houston Company, Limited. (General Electric Company.)

20810. Electric furnaces. British Thomson-Houston Company, Limited. (The General Electric Company.)

20898. Pipes or tubes for containing underground electrical cables or conductors. Chambers.

22966. Construction of dynamo and like brushes. Chaplin and Chaplin.

27849. Timing devices for turning on and off gas, electric circuits, and other agents. Horstmann, Horstmann, Horstmann, Horstmann, and Edgar.

29187. Electric igniters for explosion motors. Guillou. (Date applied for under International Convention, Jan. 2, 1904.)

1905.

1369 Electro-therapeutic ray tube. Cossor.

1820. Electro-dynamic railway traction systems. Dulait, Zelmay, and Rosenfeld.

2693. Pneumatic devices for supporting, actuating, and controlling the trolley poles of electric cars and the like. Gunyon. (Magney Manufacturing Company.)

5456. Detectors for electromagnetic waves or other weak electric impulses. Thompson. (Ges. für drahtlose Telegraphie m. b. H.)

5863. Electric train signals. Sullivan and Renshaw.

6650. Galvanic cells. Schenk.

8972. Systems of electrical distribution of direct currents by means of vapour rectifiers. Hewitt. (Date applied for under International Convention, May 13, 1904.)

10100. Overhead current collectors for electric railways and tramways. Platte. (Date applied for under International Convention, May 14, 1904.)

12690. Intercommunication telephone systems. Birnbaum and White.

NOTES.

Abandoning the Third Rail.—The New York, New Haven, and Hartford Railroad Company have decided to substitute the overhead system for the third rail on its line between Hartford, New Britain, and Bristol, Conn. It will be remembered that this line was one of the pioneers in third-rail construction.

Electrical Resistance.—At the annual meeting of the North of England Institute of Mining and Mechanical Engineers at Newcastle last week, a paper by Mr. G. C. Wood was presented giving the results of a year's work in determining the specific electrical resistance of coal and various ores. The electrical resistance of coal was found to be so high that it may be considered a very fair insulator, a fact of practical value in connection with electrical work underground. It was remarked in discussion that coal had a much higher resistance than Barton ballast, which had lately been discovered by the North-Eastern Railway to be particularly effective in preventing the return of the electric current to earth. In verification of this Mr. Walton Brown, the secretary of the institute, stated that Mr. Barton had sat on the live rail with his feet on his own ballast.

Metropolitan Railway.—The enigmatical "1st of the month," which has been the answer of officials for some time to enquiries respecting the actual start of the electric service on the Inner Circle, we have fairly good authority for believing to be Sept. 1. Still, after past experience, the public may be excused if they "hae their doots," and go on the principle that seeing is believing. For the past two or three weeks the Metropolitan Railway have been running electric trains between Aldgate and South Kensington, and this, coupled with the announcement of the steam rolling-stock of the District Railway being on the market, warrants the belief that at last the days of steam traction in the caverns of the Underground are numbered. In these times, when the cry of British decadence is so prevalent, it may be well to call to mind the fact that the delay respecting the introduction of the improved service on the Circle is not due to English muddling, but to much-vaunted Americanised methods.

New Radioactive Element.—Mr. Oskar Kahn contributes the result of his researches upon a new radioactive element which emits thorium radiation to the *Zeitschrift physikalische Chemie*, and an abstract of same appears in the *Journal* of the Chemical Society. In fractionating a mixture of bromides obtained from thorianite, it was found that whilst the radium accumulated in the least soluble fractions, the radioactivity of the most soluble portions also increased. Finally, a strongly active oxalate precipitate of about 10 mg. was obtained, which glows faintly in the dark and excites the platinocyanide and zinc sulphide screens in a marked fashion. If a current of air is blown through a solution of the substance and directed against a zinc sulphide screen, the illumination of the latter is somewhat similar to that observed in a parallel experiment with emanium. It is shown, however, that the substance cannot be actinium or emanium. The emanation from the substance is almost identical with that of thorium, but the substance itself is from 100,000 to 200,000 times as active as thorium, and is supposed to contain a new radioactive element.

Rubber Production.—A correspondent writes to the daily Press to correct previous statements as to the conditions of the rubber-growing industry in Ceylon, and in so doing he gives some interesting information. The trees are now grown from the seeds of the Para heves, imported by the Indian Government several years ago from the regions of the Amazon, which were introduced into Ceylon with great difficulty, owing to germination setting up during the lengthy voyage. The writer controverts the statement that 100,000 acres can be planted during the forthcoming year, and places the figure at 20,000, as neither seed, labour, nor land is available for the larger quantity. The area so far planted in Ceylon is 36,000 acres, and a similar amount of territory is under cultivation in the Malay States. The writer considers that estimates of the future rubber production of the world which have been published are premature, and he predicts that it will be some 15 years before the quantity of rubber produced increases by 40,000 tons per annum, which would represent an increase of about 65 per cent. on the present production. As the demand for rubber practically doubles every decade, his view that the rubber-producing industry is a promising one for the energetic and scientific planter seems well justified.

A.E.I.—Part 3 of vol. ix. of the *Proceedings* of the Italian Institute of Electrical Engineers contains, besides the reports of the meetings held in March, April, and May in various parts of Italy, the following papers: "Standardisation of Electrical Machinery and Apparatus," by Prof. L. Lombardi, delegate of the association at the St. Louis Congress; "Notes on Bonds for Rails," by D. Spallicci, C.E, Florence; "A Description of the Electrotechnical Laboratory of the Royal Naval College at Genoa and its Facilities for Research Work," by Prof. C. Garibaldi; a note dealing with the possibility of obtaining undistorted transmission of telegraphic messages under more general conditions than those laid down by Heaviside, by G. Giorgi, C E, Rome; "The Effect of Obstructions to Motion with regard to the Flow of Water through Pipes," by the same. There is also a lengthy paper dealing with the proposed hydro-electric power scheme from the Volturno, by J. Ruffolo, C.E., Naples, while Dr. A. Filippini, Genoa, deals with the voltaic arc as an electrical phenomenon. Mr. E. Jona, Milan, describes an electrostatic voltmeter for 200,000 volts. The report of the commission on a national organisation for the protection of industrial property is considered by Mr. M. Capuccio, C.E., Turin. Numerous diagrams and illustrations complement the articles, and from a note in the appendix we see that, nine members having joined the association during the quarter ended June, 1905, the membership now totals 1,135.

Power Economy on Trams.—When presenting his report for the year ending March 25, 1904, Mr. A. S. Giles, manager of the Blackburn Corporation trams, outlined his scheme for effecting a considerable degree of economy in the amount of energy used. He had separately metered the consumption of power on the various sections and logged it each day. It was his practice to calculate the energy used per car mile, and to plot this on a weekly curve against each section of the tramways, in order that he might be able to discern any abnormal fluctuations. He noticed, however, how greatly the energy varied with different drivers, and after allowing for the state of the rails, wind, and weather, this variation was found to amount to as much as 30 per cent., from which he naturally inferred that some drivers did not pay much attention to their instructions. This was confirmed by the results attained when Mr. Giles personally took a turn at driving. He, therefore, proposed that the Corporation should offer drivers a bonus of 1s. per week for every tenth of a unit per car mile they saved below 1·87 units per car mile, which Mr. Giles calculated would still allow a considerable margin of profit to the trams. A glance at the accounts for the year ending March, 1905, shows that this idea was not fruitless, though, apparently, the results were considerably

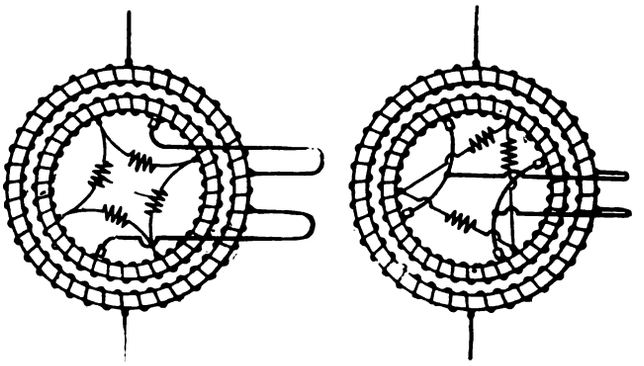
Digitized by Google

under Mr. Giles's expectations. The economy in current for the year averaged, roughly, ·06 of a unit per car mile. This shows that something appreciable can be done, and the figures seem capable of further improvement.

Iron and Steel Institute.—An attractive programme, to which we have before referred, has been issued for the autumn meeting of the Iron and Steel Institute at Sheffield on Sept. 26, 27, 28, and 29. The meetings will be held in the new university buildings. All the great armour-plate and gun manufacturing firms are opening their works, including Messrs. Firth and Sons, Messrs. John Brown and Co., the Parkgate Iron and Steel Company, Messrs. Vickers, Sons, and Maxim, Messrs. Cammell, Laird, and Co., and Messrs. R. A. Hadfield and Co., and visits will be paid to about 30 other manufacturing establishments in the vicinity. On the entertainment side of the meeting the Dukes of Norfolk, Devonshire, Leeds, Rutland, Portland, and Newcastle have given special facilities for visiting their domains, and foreign visitors will have a good opportunity of enjoying some characteristic English scenery. Some important papers will also be read and discussed. Captain Howorth (of the experimental staff of the War Office) will give some interesting results that have been obtained in the course of the Ordnance Department's endeavours to find the best materials for guns. M. Guillet, of Paris, will contribute an elaborate series of researches to ascertain what is the best kind of steel to use in motorcar construction to ensure safety, finally recommending vanadium steel. Mr. Douglas Upton, of Jarrow, will describe a manipulator for steel bars which will do away with handling; and Prof. Arnold and Mr. McWilliam have again collaborated to throw new light on the thermal transformation of carbon steels. Mr. J. E. Stead and Mr. A. W. Richards will discourse on the effects of overheating steel, and some results of the wear of steel rails will be given. The Lord Mayor of Sheffield and the Master Cutler are co-operating with the local reception committee to give a hearty welcome to the visitors, many of whom will come from America and the Continent.

Telephony in Canada.—The latest report to hand (No. 35) brings the *Proceedings* of the Canadian Telephone Committee down to July 12. It deals with the evidence given by the merchants of the chief cities, whose grievance seems to be the common one that the charges are too high. Apparently they consider that it is not very material whether the telephone system is conducted privately or by the Government so long as cheapness is secured, but most of them incline to the view that this is more likely to be attained under Government ownership, at any rate of the long lines. The Canadian merchants think that the telephone should be an article of general use, much the same as tramways—or more, for one witness stated that people who would not come out of doors to buy would give orders if they could do so over the telephone. In Montreal there are two systems—those of the Bell Company and the Merchants' Telephone Company. The former costs about £7 per annum and the latter about £5, though there appears to be little difference between in regard to efficiency. But the Merchants' Telephone Company has no long-distance connection, and the Bell Company apparently trade upon this fact. The merchants, therefore, urge the need of better facilities over trunk lines. Another grievance of the merchants is that, although subscribers, they are charged the usual 2½d. per call when using the public stations. A witness from Toronto stated that, in consequence of the oppressive restrictions of the Bell Company, the Retail Merchants' Association negotiated with the Stark Company for the installation of a service at £1. 5s. per annum and ½d. per call up to £5. 12s. per annum for private houses, the maximum for business places being £7. 5s. The difficulty, however, was that the service was only a local one, and the association, therefore, considered that the trunk lines should be owned by the Government, who should give facilities to all local companies. This was followed by other evidence of a similar character, after which another adjournment was called.

Repulsion Induction Motor.—A self-starting single-phase commutator motor, which has a speed limit at or near synchronism, has lately been designed by M. Milch, who has obtained a patent for same in the United States. In construction the machine differs inappreciably from a repulsion motor. A slight change is made in the rotor winding so that points symmetrically located thereon are joined together through impedances. These impedances are highly inductive, but contain very little resistance. When the rotor is stationary very little current flows through the impedances, and the machine receives its starting torque on account of its repulsion motor features.



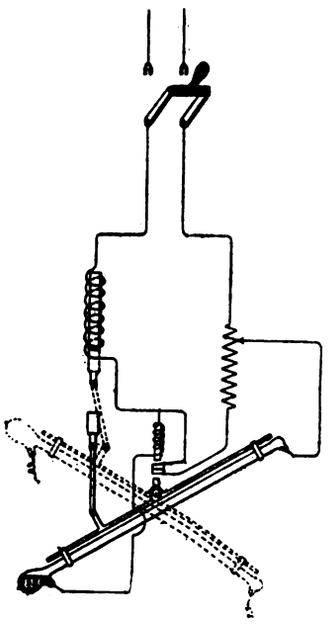
At synchronism, however, the rate of change of current through the impedances is zero, and they act as low-valued resistances to short-circuit the rotor winding, which consequently becomes the secondary to the stator winding, which acts as the primary of a single-phase induction motor. In order to compensate for the exciting current of the induction motor, the circuit to the rotor brushes is opened and there is impressed upon them an E.M.F. of the proper value and time phase position. This E.M.F. is obtained from taps upon the primary winding, as indicated in the accompanying illustrations, which we reproduce from the *Electrical World* of New York. At starting this small voltage is overpowered by the voltage induced in the rotor windings, and the motor acts as though the brushes were short-circuited.

The Passing Locomotive.—A Sydney *Morning Herald* has been sent to us containing an article by Mr. E. Kilburn Scott, which is said to be an electrical sidelight on "The Locomotive Contract." Reading between the lines, we gather that locomotives made in the colony are being called for by a certain contract, and that to construct these new works would need to be established either by the Government or private enterprise. Mr. Scott's article claims that any such expenditure would be wasteful, because the steam locomotive is doomed. After giving examples of recent electrification of railways, he says: "All the elevated railways in New York, Boston, and Chicago have been electrified for some time, and there are literally 'packs' of displaced steam locomotives for sale. A lot of about 800 (some practically brand new) were hawked about England when the New York Elevated changed over to electricity. If they are not now on the scrap heap, that is undoubtedly their destination. Yet with all the loss which scrapping so much plant entailed, the elevated railroads in America are in a stronger and more healthy financial position than ever before. This being the

Digitized by Google

position of affairs, it will easily be seen how great a risk employers, whether they be the Government or a private firm, are taking if they deliberately lay out much money on special plant for making steam locomotives. It appears to the writer to be more like philanthropy than business to accept an order carrying with it such a condition or necessity. Regarding the workmen, the trade which is likely to be hit most is that of the boilermakers, for in an electric locomotive or motorcar much of the framework besides the wheels, axles, etc., are the same, but the boiler inevitably disappears. Bodies of the motorcars are a matter of coach-building, but the motors, controllers, distribution system, sub-station plant, etc., besides a large proportion of the central power station plant, call for a different class of work from any that is now executed in this country. Anyone anxious to erect new or to re-equip old works here should do so with a view to undertaking large electrical engineering contracts. Enough electrical machinery has been imported during recent years to keep a decent-sized works going."

Automatic Starter for Mercury Vapour Lamps. A patent has been granted in the United States to Dr. M. von Recklinghausen for a tilting device designed to start mercury vapour lamps automatically. The apparatus is shown in the accompanying illustration, reproduced from the *Electrical World* of New York. The lamp, in the form of a long tube, is suspended so that in its inoperative position it will be tilted far enough to prevent connection between the electrodes through the mercury. By means of an electromagnet the lower end of the tube is lifted so as to cause the mercury to form a bridge between the terminals, and the tube is then tilted still further to break the connection.



The coil of the electromagnet, after doing its work of lifting the lamp, remains in series therewith as an inductive resistance. An auxiliary switch which serves for completing the circuit through the coil of the lifting magnet when the lamp is in its inoperative position, is opened when the lamp is fully tilted and the mercury vapour has been rendered conducting.

Artificial Abrasives.—A report recently issued by the United States Geological Survey testifies to the rapidly-growing use in the country of abrasive materials, including carborundum, crushed steel, alundum (artificial corundum), and adamite. Of these, carborundum and alundum are manufactured in the largest quantity, and are of the greatest value, carborundum being appraised at from 4d. to 5d. per pound. The total production of these artificial abrasives in 1904 amounted to 11,870,380lb., valued at £167,000, or over one-half the value of the production of natural abrasives, which was some £300,000. The production of carborundum in 1904 amounted to 7,060,380lb., an increase of 2,300,490lb. as compared with the production of 4,759,890lb. in 1903. This is the largest production in any year since the beginning of the manufacture of this abrasive, and illustrates the increasing demand for it. With the exception of one year (1902) there has been a continual increase from year to year in the production and use of carborundum, and in that year the decrease was due to a scarcity of supplies used in the manufacture of the carborundum. The increase in the production of carborundum since the industry was started in 1892 has been indeed remarkable. In that year the production amounted to just 1,000lb., while for 1904 it totalled, as shown above, over 7,000,000lb. The manufacture of artificial corundum from a bauxite which has been developed and put on a commercial basis by the Norton Emery Wheel Company, of Worcester, Mass., at its plant at Niagara Falls, New York, has meet with great success, and this abrasive, which is known commercially as alundum, is giving most satisfactory results. The greater part of this material produced by the Norton Emery Wheel Company is used by the company itself in the manufacture of its various emery wheels, stones, etc. It makes a clean, fast-cutting abrasive, being nearly absolutely free from any kind of impurity, and has proved its excellent qualities in actual use. There is another artificial corundum that is being used as an abrasive, but it is only obtained in small quantity, as it represents a by-product of the Goldschmidt thermit process of the reduction of many of the metals. At the present time none of this corundum is made or put on the market in this country, but at the German factories where the Goldschmidt thermit process is employed it is utilised as an abrasive. In 1904 there were 4,020,000lb. of alundum manufactured, only a small portion of which was put on the market in the crude form, the average price being 3½d. per lb.

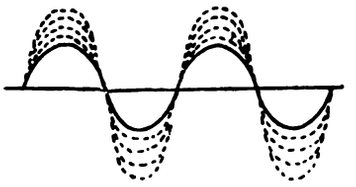
Electro-Chemistry.—Messrs. H. N. Morse and L. S. Taylor recently contributed to the *American Chemical Journal* an article describing an electrical method for the estimation of carbon and hydrogen in organic compounds, of which an abstract appears in the *Journal* of the Chemical Society. The advantages claimed for this method are that the apparatus is small and compact, the waste of heat energy is much smaller than that of the ordinary method, and the time required in preparing for and carrying out a combustion is considerably reduced. Two forms of apparatus are described. The first of these consists of a thin glass combustion tube, 350mm. long, 15mm. in internal diameter, and closed at one end. The open end is fitted with a caoutchouc stopper, through which pass a porcelain tube, 250mm. long and 6mm. in diameter, a glass tube conveying the products of combustion to the absorption apparatus, and a thick platinum wire. The platinum wire is connected inside the combustion tube to a finer platinum wire, which surrounds the porcelain tube in a spiral coil and finally passes down through the porcelain tube to the exterior, the lower part being composed of thicker wire. The oxygen or air is led into the combustion tube through a glass side tube, which is attached to the porcelain tube outside the stopper by means of indiarubber tubing. In carrying out a combustion, the boat containing the substance is placed at the closed end of the tube, a roll of copper gauze about 60mm. long is placed next, the indiarubber stopper carrying the tubes and platinum wire is inserted, and the glass delivery tube is attached to the absorption apparatus. Pure dry oxygen is passed slowly

Digitized by Google

through the tube, and the electric circuit is closed through a regulating rheostat. The current is increased until the wire becomes red hot, and the roll of copper gauze and the boat containing the substance are then heated by means of a gas flame. The time required for a combustion is usually about half an hour. The amount of electrical energy consumed is about 3·6 amperes at 54 volts during the time when the highest temperature is maintained. The second form of apparatus described differs in being composed of a somewhat longer combustion tube, which is open at both ends. Both forms of apparatus are fully described with the aid of diagrams. The results of a series of combustions are quoted for the purpose of illustrating the applicability and accuracy of the method, and an account is given of the precautions which must be observed in the combustion of substances containing nitrogen, halogens, or sulphur.

7,500-kw. Turbines.—The New York Edison Company has concluded negotiations for two 7,500-kw. turbo-generator units for the illumination of the city. This plant is to be installed in one of the largest and most up-to-date American central stations—Waterside station No. 2, which, it is stated, will ultimately contain 10 units of the same size. The compactness of the new unit is evidenced by the small space it requires. Roughly, its over-all dimensions are: length 50ft., width 17ft., height 15ft.; floor space 850 square feet per unit net, or ·113 square feet per kilowatt, this being less than a half of the area occupied by the engine-type units. A condenser of the surface type will be located beneath the turbine in the foundations proper. The makers state that this arrangement is in all respects equivalent to that claimed as the special property of the vertical type of turbine, which, the makers of the latest type state, needs considerable extra space for condenser and turbine auxiliaries. The new turbines will operate at 175lb. steam pressure approximately, 28in. vacuum, and 100deg. superheat, the normal speed of the unit being 750 r p m. Under these conditions the economy of the new unit is calculated at about 16lb. per kilowatt-hour at full rated load. There will be a minimum overload capacity of 50 per cent., or each unit will be capable of developing full rated load without the use of a condenser. A distinctive feature is that the turbine gives its best economy at about full rated load, although a large overload capacity is at all times instantly available when required without material sacrifice of efficiency. At this maximum load each turbine will develop over 15,000 h.p. at the shaft, which is reckoned as being the greatest amount of power ever developed in a single prime mover in stationary service. The direct-connected turbo-generators will be of standard Westinghouse construction, delivering 6,600-volt three-phase current to the high-tension network at a frequency of 25 cycles per second. The generators will follow the new enclosed construction, thus eliminating the hum associated with high-speed turbo-generators. The efficiency at full rated load approximates to 97½ per cent. Each generator will be capable of sustaining for several hours an overload capacity of 50 per cent. within reasonable temperature rise. As illustrating the rapid advance of the turbine, it may be mentioned that when, only a few years ago, Waterside station No. 1 was equipped with Westinghouse vertical three-cylinder compound reciprocating engines of 3,500 kw. capacity, these were probably the highest type of large engine construction. It may be noted that simultaneously with the action of the New York Edison Company, three Westinghouse turbine units of the same size have been adopted by two large Brooklyn power stations, the Brooklyn Heights Railway Company having ordered two of these units and the Brooklyn Edison Company another.

Long-Distance Telephony.—The *American Telephone Journal* published recently an article by Mr. Newton Harrison on the loading of telephone lines for long-distance service. The article is a description of the system of Prof. Pupin of introducing inductance into a telephone line in order to secure the transmission of speech over long distances. The amusing feature of the article, however, is that the illustrations are absolutely contradictory to the text. The author explains how the characteristics of a musical note depend upon the instrument producing it. He says: "In other words, if the note C is heard from the piano, violin, or cornet, although it is exactly the same number of vibrations per second from each instrument, the overtones or harmonics, as they are also called, unerringly point to the different sources of sound. The number of overtones and the character of them produce the distinguishing difference. 'Timbre' (variations in voices and sound) is thus due only to overtones, and not to the necessary vibrations which constitute the note itself. And in this respect it is possible to understand the peculiarities of the human voice; why, in a sense, personality is associated with it; why the voice is the means of identifying the owner. The number of overtones are the distinguishing feature in connection with the volume of sound produced. A rich voice has magnitude and many harmonics. A thin voice, a piping treble, is without volume or sufficient overtones to make it pleasant. It is this which marks the difference between voices, and for that reason telephony cannot consistently succeed unless the preservation of such tones becomes one of its greatest object." The author would seem to have then given his article to an untechnical artist in order to illustrate these overtones. The result is as shown in the accompanying



WAVE SUPPLIED WITH OVER-TONES OR HARMONICS

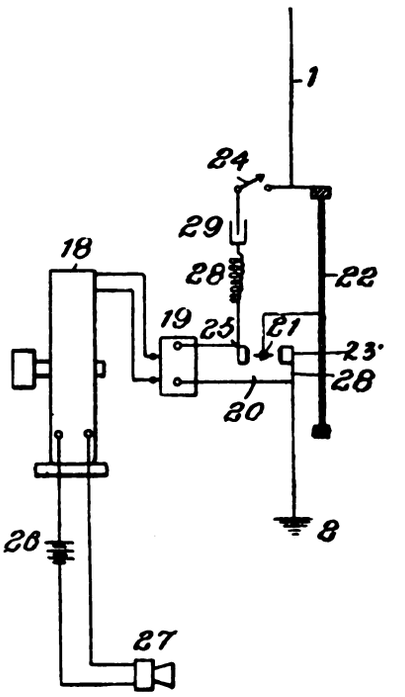
illustration, in which the overtones are shown as vibrations of the same frequency as the principal tone but of increased amplitude. The other illustrations showing how the amplitude is reduced in long-distance transmission are also drawn with the same idea, and there is nothing in them to explain that certain high-frequency vibrations are more apt to be damped down on telephone lines than other notes with a lower frequency.

Electrical Progress in Mexico.—We have previously alluded to the rapid expansion that has lately taken place in Mexico in the use of electricity for various industries, the abundant water supply of the country enabling electrical energy to be employed in cases where the cost of steam would be prohibitive. One of the largest industries to benefit by this state of affairs is mining. Recently an electrical plant has been installed to supply the important regions of Necaxa and El Oro. The transmission line is 100 miles in length, and the station is designed for a capacity of 80,000 h.p. Apparently, it is proposed to run electric railways from the mining regions for the conveyance of the ore. The Rosa Amarilla copper mines, in Gaudaljara, which have suffered in the past through the cost of power, now contemplate the erection of a large hydro-electric plant to be used both for operating the mine machinery and also for a railway to the Pacific port of Navidad. It is noticeable that an American concern is again to the fore in this con-

Digitized by Google

nection, a company from the States which has an interest in the mines having applied to the Federal Government for a concession to build the plant and railway. Another concession for power development for mining, irrigation, and railroad is that obtained by a company in the State of Jalisco. The inland mountain lake of Chapala holds sufficient water to irrigate 300,000 acres of fertile soil in the valleys below, and to furnish several hundred thousand horse-power for industrial purposes. A power plant is to be constructed on the Santiago River near by, and transmission lines will run through the richest mining regions in the vicinity. The Santiago River has a variable fall of 20ft. to 30ft. per mile, and the utilisation of its water for electric transmission is rapidly being appreciated by mining companies. The famous Perez concession for using the waters of this river has recently come into the hands of a company that is constructing a power plant to transmit electricity to the city of Aguascalientes, a distance of 110 miles. It is proposed to develop 30,000 h.p. at once. This will be sold to mining and irrigation companies along the route, and also to street railway companies in the terminal city. At Velardena, in Durango, extensive hydro-electric improvements are being made by American engineers to operate new smelters and to drive mining machinery, the mountain streams furnishing the power. In many other parts of Mexico schemes are being devised to turn to good account the energy stored in her mountain streams. The aim of the companies is to combine transportation, lighting, and mining operation in one enterprise. In a few instances the grouping of mines in one locality has justified the investment of large capital in hydro-electric enterprises independently of other uses; but in some districts the transmission lines have their terminals in distant cities where electricity can be sold in bulk for industrial and lighting purposes. The effect of this policy upon mining interests in Mexico has already been demonstrated in a number of instances. Rich mining regions that were formerly neglected have gained a new value, and are being developed with great rapidity. Mining camps are springing up all along the transmission lines, and several of the pioneer companies have had to enlarge their electrical plants to keep pace with the demand for power in mining. It is tolerably evident from this that there will be a good demand for electrical machinery and equipment, and though, from their contiguity, our American cousins must have a certain advantage, it behoves English manufacturers to see that Brother Jonathan does not appropriate the whole of the prize.

Fessenden's Wireless Telegraphy.—Some patents recently granted in the United States to Mr. R. A. Fessenden, of Washington, relate to improvements in his system of wireless telegraphy. Several interesting phenomena have been observed in connection with systems of wireless telegraphy such as this. One is that under certain conditions, not yet fully understood, the pitch of the transmitted speech may be raised, sometimes one octave and sometimes two octaves. This only occurs, however, with certain methods or with certain adjustments, and may in most cases be obviated by altering the adjustments, but it does not in any case seriously affect the distinctness of the speech. Another point of interest is the extreme clearness and sharpness with which the speech is transmitted, the sound arriving at the receiver as though a person at hand were speaking, except where a transmitter is used for varying the field excitation. One cause of this clearness of articulation is found in the fact that the capacity effect, which is so prejudicial to good speech, is absent in the transmission of electromagnetic waves, and the higher harmonics of the voice are transmitted without distortion. An apparatus shown in the accompanying illustration, which we reproduce from the *Western Electrician* of Chicago, is employed, consisting of a high-frequency generator (18) and a transformer in connection with the generator in order to raise the voltage. A double spark-gap is used, one of the terminals (25) being connected to the transformer and the sending conductor, the latter connection being formed, if desired, by switch (24). The other outer terminal (23) is connected to earth and to the opposite terminal of the transformer. The intermediate terminal (21), which is electrically connected to the sending conductor, is attached to a diaphragm (22)—as, for example, the diaphragm of a transmitter. On exciting the transformer a discharge may be caused to pass from the terminal 25 to the terminal 21, and thence to terminal 23. The potential across the terminals 25 and 23 may be made to have any desired value by regulating the potential of the transformer (19) or the current flowing in the field circuit containing battery (26) and adjusting the resistance (28). If the switch (24) be



left open, the potential of the intermediate terminal (21), and, therefore, that of the upper portion of the sending conductor, will vary with the position of the terminal 21, and on the vibration of the diaphragm — caused by sound waves—the intensity of the radiation from the sending conductor will be caused to vary in a manner corresponding to the sound waves. The apparatus may be used for the transmission of words by closing the switch (24) and adjusting the terminals of the spark-gaps, so that no discharge passes between terminals 25 and 21, but mainly between terminals 21 and 23. This arrangement is stated to give good results, as the radiation from the sending conductor will vary as the gap between the terminals 21 and 23 varies with the movement produced in the diaphragm by the sound waves. The resistance (28) may be so constructed as to form a flexible support for the terminal 25. We observe that another patent granted to Mr. Fessenden relates to a form of receiver called a "liquid barretter," in which both the highly oscillatory currents to be detected and the constantly flowing current from a local source flow through a constricted conducting fluid path, and the highly oscillatory currents produce a change in the amount of current flowing through the local circuit.

ELECTRIC 100-TON CRANE AT DUBLIN.

The illustrations herewith show the general construction and electrical details of a new crane recently completed for the Port and Docks Board of Dublin. The crane, which is of the revolving tower type, is built for a normal load of 100 tons, and has been successfully tested with 150 tons. It was built and erected by the Vereinigte Maschinenfabrik Augsburg und Maschinenbaugesellschaft Nuernberg A.G., whose works are at Nuremberg, Bavaria, and was started to work in the middle of last June. The electrical equipment was supplied by Messrs. Siemens Bros.

The rotating part of this gigantic crane (Fig. 1) consists of a vertical crane post with a double cross-arm. The lower part of the crane post rests in a cylindrical bearing, whilst the weight and horizontal pressure is borne by means of 30 rollers on a bearing fixed to the trestle surrounding the crane post. The gear for hoisting and for working the traveller (Fig. 2) is in the machine

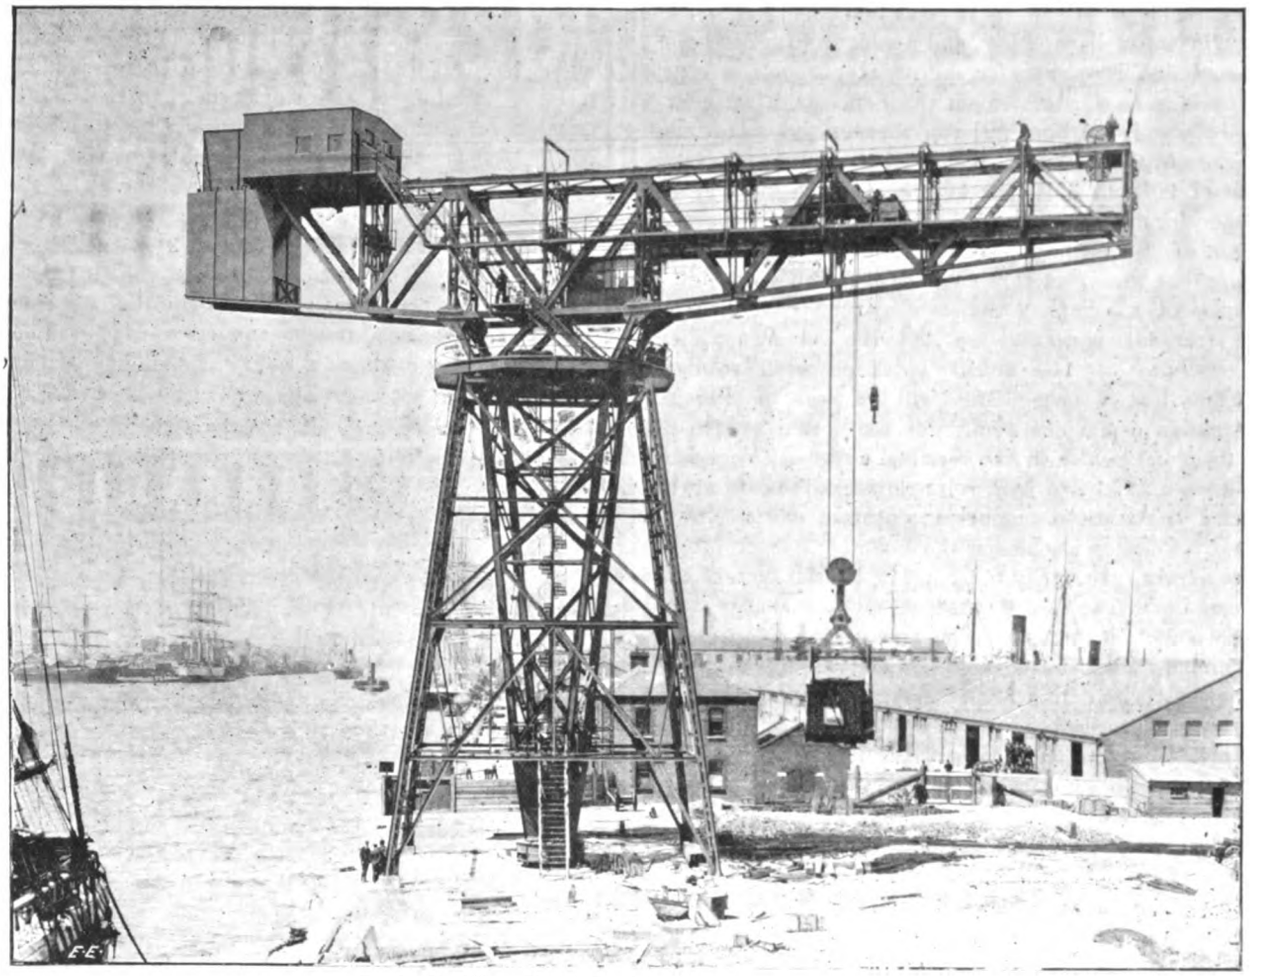

FIG. 1.—The 100-ton Electric Revolving Crane as erected at Dublin.

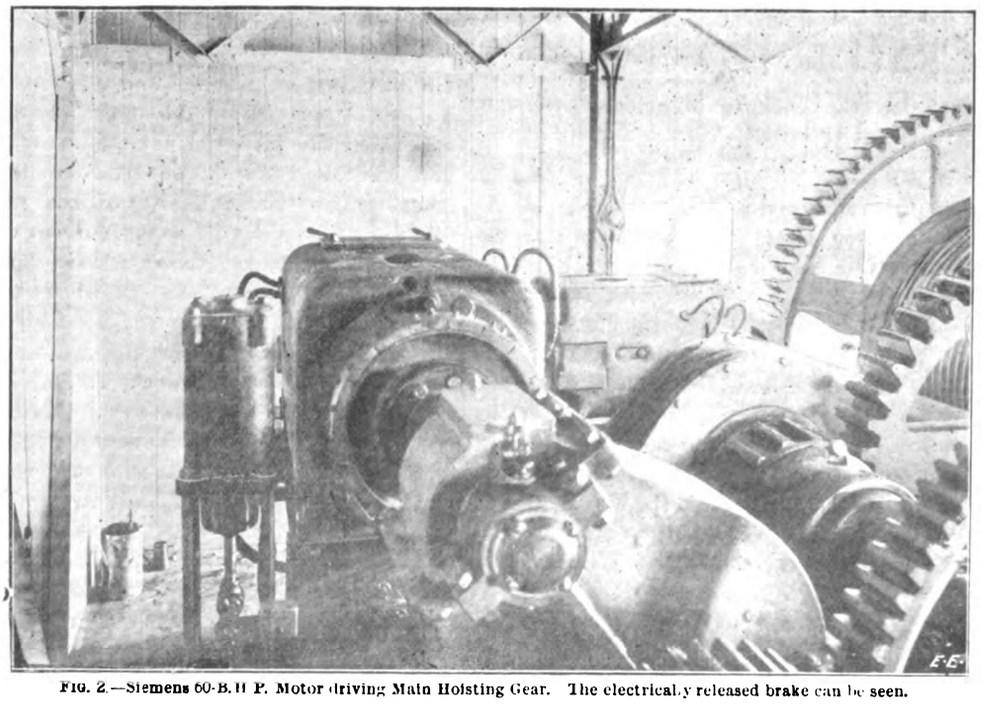

FIG. 2.—Siemens 60-B.H.P. Motor driving Main Hoisting Gear. The electrically released brake can be seen.

Digitized by Google

room, which, together with the counter-weight, is erected on the short cross-arm. The traveller (Fig. 3) runs on the long cross-arm between the two main supports which are connected to each other by a horizontal bracing; this arrangement ensures a greater rigidity of the sides than the usual construction. An auxiliary hoisting

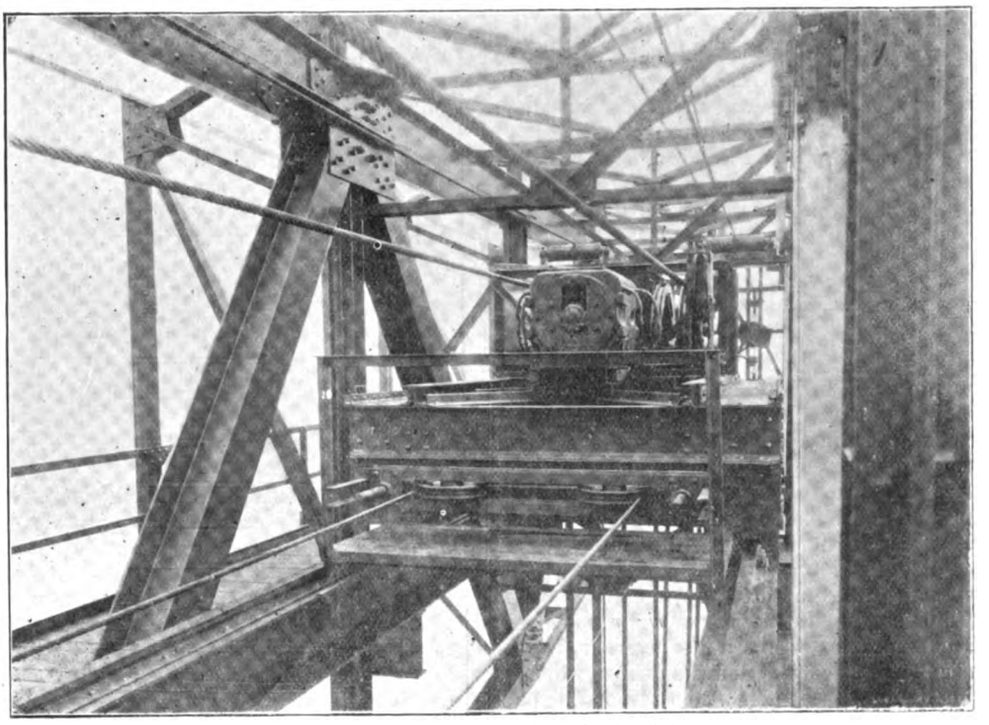

FIG. 3.—View of the Travelling Gear, showing Motor.

apparatus of 20 tons working capacity and 30 tons maximum carrying capacity is erected on the traveller. The slewing mechanism (Fig. 4) is arranged on the upper platform, at the junction of the crane post and the cross-arm. The driving cab from which the crane is operated, by means of the controllers, is situated between the main supports of the cross-arm, near the centre. From this spot

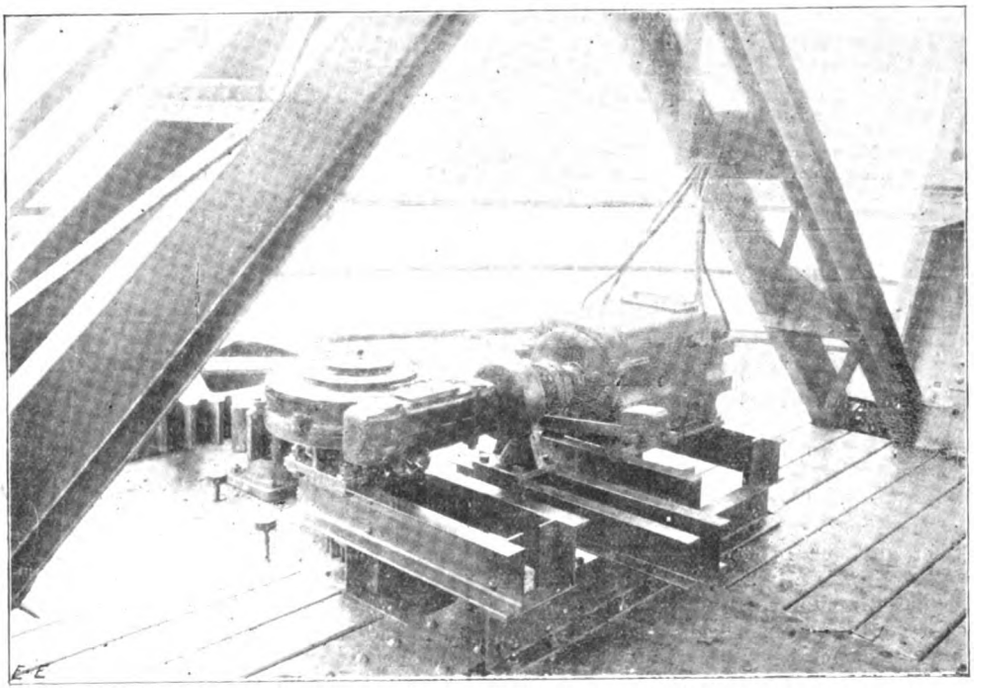

FIG. 4.—Motor-Driven Slewing Gear for Dublin 160-ton Crane.

the driver has a good view over the working field of the crane. Conveniently arranged staircases lead to the machine-room and to the platforms on the cross-arm, as well as to the driving cab. The chief dimensions of the crane are as follows: greatest height of the load hook above quay wall, 70ft.; greatest hoisting height, 100ft.; greatest radius for 20 tons, 80ft.; greatest radius for 150 tons, 75ft. The working speed is when hoisting 150 tons, 5ft. per minute; 50 tons, 10ft. per minute; 20 tons, 20ft. per minute; speed of traveller, 28ft. per minute. Time taken for a complete rotation, eight minutes. The crane is used for loading large and heavy articles—for instance, boilers, machines, guns, etc. The trial movements made singly and in combination, with the loaded crane, were carried out to the complete satisfaction of the purchasers. The ports of Hamburg and Emden possess already five cranes of the same type, which were also supplied by the same makers.

The electrical equipment supplied by Messrs. Siemens Bros. is of the 500-volt continuous-current type, and the motors are specially designed for crane work. The horse-power of the motors and their speeds are as follows: The main lifting motor is of 60 b.h.p., and runs at 650 r.p.m. This motor, with its gear and electrically-controlled band brake, is shown in Fig. 2. The auxiliary lifting motor is placed on the traveller itself. This motor is of 40 b.h.p., and runs at 650 revolutions. Its position on the traveller

Digitized by Google

is shown in Fig. 3. The travelling motion motor is of 30 b.h.p., running at 750 revolutions, while the slewing motion is worked as shown in Fig. 4, and is a 15-b.h.p. motor running at 570 revolutions. The controllers are of Messrs. Siemens Bros. and Co.'s standard M. C. complete reversing type, fitted with hand-wheels, indicating the "off" position. The lifting controllers have a greater number of points of control on the lifting side than on the lowering side. The slewing and travelling controllers have the same number of points on each side. The regulating resistances for the main lifting motors are of the grid type, but all the other motors are equipped with resistances of Messrs. Siemens's brick type. The electrically-controlled brakes on each motion are series wound, and are designed to hold the loads should the current be accidentally interrupted. The switchboard is simple in design, with an iron frame and a double-pole switch and two single-pole fuses for each motor.

The supply of motors for crane work is a speciality of Messrs. Siemens Bros., who have adopted a new system of rating based on their experience in such electric driving. A few words as to this rating will be of interest. It is, of course, clearly understood that with cranes, hoists, capstans, and other machinery of this class, the work demanded of the motor is of a very intermittent nature. The actual size of the motor required for any particular motion of a crane depends entirely upon how intermittent this work may be. It is evident that the controlling factor is the ratio between the period during which the motor is giving out power and the period for which it is remaining idle. In the case of the lifting motor of a jib crane handling general cargo out of ship into truck or *vice versâ*, Messrs. Siemens Bros. find that this ratio, on the average, is about 1 to 8. That is to say, for every minute during which the motor is exerting its full power there is a corresponding pause of seven minutes during which the motor is at rest. These figures are in the nature of an average taken over a whole day's work. It is evident, therefore, that a motor which will work under these conditions without overheating or sparking from the electrical point of view is amply large enough for the work required, and such a motor should be selected from the column in the firm's motor tables headed "one-eighth load factor." For the convenience of sub-division, they have arbitrarily taken a period of 12 minutes as being the time taken for one complete cycle of operations, so that, upon this basis, a motor which was rated to give out its full power for 1½ minutes and then allowed to rest for 10½ minutes would be working at a one-eighth load factor—that is, one-eighth of 12 minutes' working and seven-eighth of 12 minutes' resting.

Load factor.	Minutes working.	Minutes resting.
⅛	2	10
¼	3	9
⅓	4	8
½	6	6

The above period of 12 minutes can be varied within very wide limits without materially affecting the final result, the limit as to the maximum time of working depending on the size of machine. In crane work generally, the time for a complete cycle of operation is almost invariably considerably under 12 minutes, being more of the nature of a one or two minutes' cycle. In some cases, however, of crane and other intermittent working, a motor may have to work at full load continuously for much longer periods than the limits of the load factor rating would permit. For instance, it is possible for a machine to have to work for two hours continuously and then rest for 14 hours, thus calling for a machine to work at apparently a one-eighth load factor, whereas another motor may have to work for 1½ minutes continuously and rest 10½, this also being a one-eighth load factor. Taking as an example motors to give 23 b.h.p. at about 400 r.p.m., with a temperature rise at no time to exceed, say, 80deg. F., to satisfy the first case it would be necessary to use a Siemens 15·2 size motor, whereas the second could be met by a 11 C. size—that is, a machine three sizes smaller. In the first example the period of work is so long that the motor has ample time to heat up before it has an opportunity to cool down during the rest, whereas in the second case the heat generated during the short run has time to dissipate itself during the pause which follows. From the above it will be seen that, although the apparent load factor under which the two machines have to work is the same, the length of run is an important consideration, and bears very largely upon the size of machine required. It should be noted that the smaller sizes of motors attain their full heating limit much more quickly than the larger sizes, owing to the greater weight of material in the latter and the rather higher efficiency. On the other hand, however, the radiating surface per watt lost is rather greater in the smaller motors than in the larger, and, therefore, although they heat more quickly, they also cool down more quickly. It will be seen, therefore, that in selecting crane motors two factors must be considered—firstly, the actual intermittency of the load; secondly, the period for which the motor may be called upon to do its full work without stopping.

Regarding the rating at which the firm usually put forward motors for crane work, providing the speed at which the various movements of a crane or other piece of apparatus working intermittently are required to work is definitely known, it is fairly easy to calculate approximately the load factor at which the motors will have to work. For instance, taking a jib crane lifting and slewing by separate motors, a complete cycle of operations would be as follows: adjusting and hitching on the load, raising the load, slewing, lowering the load, unhitching the load, raising the empty hook, slewing back, lowering the empty hook. As a matter of fact, raising and lowering the load and slewing are frequently performed together, but, as far as the motors are concerned, this is immaterial. By adding up the total periods of time during which the motors are called upon to give out their full load—of course, making due allowance for the time they are on light load raising the empty hook, etc.—and dividing the total time of a cycle by this figure, the load factor will be obtained. Lifting motors almost invariably have to work at lower load factors than slewing, as the latter are practically always working at full load while in operation. For lifting motors the load factor may vary from about one-third for grab coaling cranes down to one-twelfth, or less, for general merchandise cranes, and the slewing motors respectively one-half down to one-eighth. These figures naturally depend upon circumstances. It is, however, inadvisable to assume a lower rating than about one-eighth load factor, as mechanical considerations regarding the spindles and possible sparking at the commutator then becomes important. For shop and overhead travelling cranes a one-sixth load factor for lifting and cross traversing, and one-fourth load factor for travelling, suitably meets the conditions of average practice, and for capstans and winches one-sixth to one-fourth load factor is a fair allowance. Only in very rare instances do conditions demand a higher rating than one-third.

The tables supplied by Messrs. Siemens Bros. show how the maximum horse-power of their different motors can be varied according to the load factor.

THE COOPER HEWITT MERCURY VAPOUR LAMP.

Not so many years ago the transmission of electric current through gases was merely a scientific experiment which, although an interesting study for electricians and physicists, had no actual value from the commercial point of view. As far back as 1860 it was known that electric light could be generated by passing current through mercury vapour, but it remained for Mr. Cooper Hewitt to construct a lamp which would be at the same time serviceable and efficient. When the lamp was first shown at the commencement of this century it aroused the greatest interest throughout the world (it was described in our columns in January, 1903, vol. xxxi., p. 87). Since then it has been developed on commercial lines with great success.

The latest type of lamp (Fig. 1) consists of a glass tube to which is sealed a condensing chamber. Into the glass tube the current is led through platinum wires sealed into the glass. Mercury is always used for the negative electrode, and either more mercury or any other metal like iron or copper for the positive. The tube is

Digitized by Google

exhausted to a high degree and sealed. The length of the lamp is about proportional to the voltage—*i.e.*, the 50-volt type is about half the length of the 100-volt type. The current passes through a small inductive resistance consisting of several hundred turns of wire round a laminated core. From this coil it passes through a regulating resistance to the lamp. The other pole goes direct to the lamp. When the line potential is put on, the lamps do not immediately start burning. This is due to the great reluctance of the negative. In order to reduce the resistance, Hewitt uses a disintegrating electrode such as the mercury itself, which is the best material for the purpose. It steams away from the surface, condenses again on the walls of the tube, runs back to the negative, and can, therefore, be used over again. To bring the electrode to a state of disintegration, it can either be connected to the positive and then separated from it, or else by putting a high tension on this negative electrode. Physically expressed, the mercury has an extremely high starting but a very low running potential. The starting potential, or it may be called the breakdown potential, is a good many thousand volts, possibly 6,000 or 8,000 in some cases, or even 15,000 to 30,000 volts, whilst the running potential—that is, the drop across the negative electrode in a burning lamp—is only about five. Once the lamp has been made conductive by means of the breakthrough of the dielectric on the surface of the negative—that means when the negative has been brought to a state of disintegration—the lamp conducts extremely well. The usual method of starting the lamp is by tilting it until

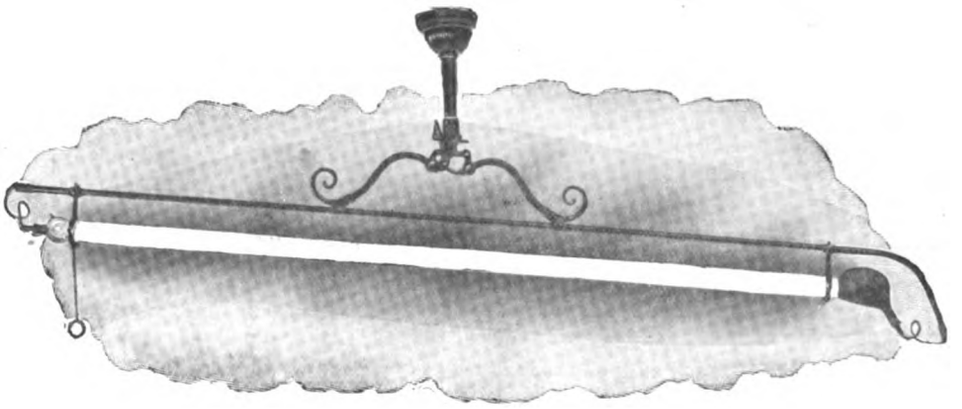

FIG. 1.—The latest form of Cooper Hewitt Mercury Lamp.

there is a thin stream of mercury all along the tube, thus directly connecting the two electrodes, as mentioned above. This starts the disintegration of the negative, and when the lamp has been returned to its original position it will burn without further attention. The actual process which takes place when the lamp is burning is extremely difficult to explain. Dr. von Recklinghausen describes it as follows: "The most plausible explanation of the process, although perhaps not tenable from a physical point of view, is that the current enters the lamp at the negative electrode, and then passes after disintegrating the mercury into the vapour, and thus up to the positive electrode." Another method of starting the lamp was shown by Cooper Hewitt in 1902. The negative electrode is brought to disintegration by means of an auxiliary positive electrode. With a suitable voltage the current then jumps over to the main positive electrode and the auxiliary is then cut out.

The Cooper Hewitt lamps burn without flickering, but a certain movement is noticeable at the negative electrode. The cause of this is that the current passes from the surface of the mercury into the vapour by means of exceedingly small bright particles which move about the surface like will-o'-the-wisps. Small pits or depressions of about $\frac{3}{16}$in. to $\frac{1}{4}$in. in depth are also visible on the mercury surface. It seems as if the vaporised particles of mercury are searching for spots having suitable surface voltage or temperature only to destroy them when found. By adding suitable elements to the mercury these particles can be collected in a ring round the glass, or they will adhere to a platinum wire placed on the surface of the mercury, but after a few hundred hours the section of the wire decreases to a very great extent, which shows how great the reaction of the disintegration is. The size of the disintegrating particle depends apparently upon the amount of current passing into the vapour. In lamps of large diameter a dark space can be seen above the negative. This space, apparently, increases as the pressure of the gas in the lamp decreases and its temperature is lower than that of the luminous vapour. This is evident from the decidedly increased condensation of that portion of the walls of the lamps when burning at a low amperage. The vacuum in the lamp must be good, as otherwise the efficiency will be reduced. Under normal conditions, the drop in voltage at the negative terminal amount to five to seven volts, and at the positive terminal to about seven to nine volts. If mercury is used as the positive electrode, the drop will be increased by a few volts. As this is always greatest when the lamp is cold, the starting curve of the lamp is, in consequence, rather exceptional. It rises first, then drops, then rises again, and finally remains steady. This variation is caused by the rising curve of gas potential affecting the descending potential curve of the positive electrode.

The efficiency of the lamp is very great, amounting to about ·33 to ·45 watt-candles, or about eight times the efficiency of incandescent lamps. Further, the extent of the lighting surface obviates the use of reflectors, shades, etc., as there are no deep and accentuated shadows. The most important point about the lamp is that it emits rays which do not fatigue the eye. The light is exceedingly actinic, and is, in consequence, of great value to photographers and lithographers. Experiments have been carried out with the view of making the colour of the light more pleasing. This can be done either by adding red rays from the sources of light, such as incandescent lamps, or by fluorescence—*i e*, by transforming some of the mercury light waves into red wave-lengths. Rhodamin on silk is very suitable for that purpose. There is, of course, a certain amount of light lost in this modification, but by expending about 25 per cent. for this purpose a very pleasant illuminant is attained.

Many attempts have been made to manufacture other lamps similar to the mercury vapour type but using different metals. The difficulties encountered, however, were too great. Mercury is an ideal electrode as far as disintegration and regeneration is concerned. If other metals are used, difficulties arise in the regeneration of the negative, for they do not run back to the negative, as is the case with mercury. The glass also becomes affected, especially in the case of alkali metal, and the resistance of the gases makes it problematical as to whether a commercially successful lamp can be made except with mercury. Some lamps have been made lately of fused quartz glass, which allow all the ultra-violet rays of mercury vapour light to pass through instead of absorbing them, as is the case with incandescent lamps. This feature should be of very strong importance for the Finsen medical treatment.

With good treatment the life of a Cooper Hewitt lamp is very long; some have been used for over 15,000 hours. The decrease of light in good lamps amounts to about 20 per cent. during the first 1,000 hours, after which the candle-power remains constant. It is important not to burn the lamps with excessive pressure. This can be regulated by the resistances, of which the induction coil forms the most important part. The function of the coil

Digitized by Google

can be explained as follows: There is a disinclination on the part of the negative electrode to remain in a state of disintegration. This is shown by the increase of resistance and the consequent decrease of the passing current. The momentary decrease of current causes an increase in pressure in the induction coil, which in its turn increases the process of disintegration in the electrode. The small variations are not noticeable at the ammeter for the reason that they take place so very rapidly. For 110-volt circuits the best practice is to use 75 to 80-volt lamps; the remainder of the voltage is absorbed in the resistance.

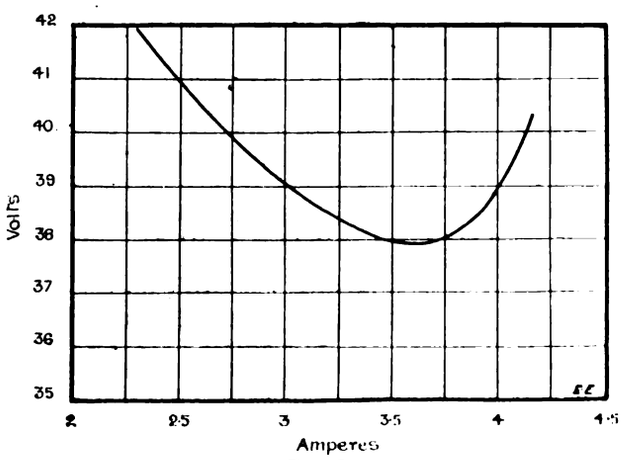

FIG. 2.

If smaller lighting units are desired, two lamps each of 40 volts are connected up in series. Smaller units using less than three amperes are, on account of the difficulties with the electrodes, not practicable. Larger lamps offer difficulties to the glassblowers.

With the old types of lamps great difficulties were experienced with the heat produced by the current and the consequent increased density of the vapour. If the lamps were not water-cooled, they burned very unsteadily. They were affected to a very great degree by the temperature of

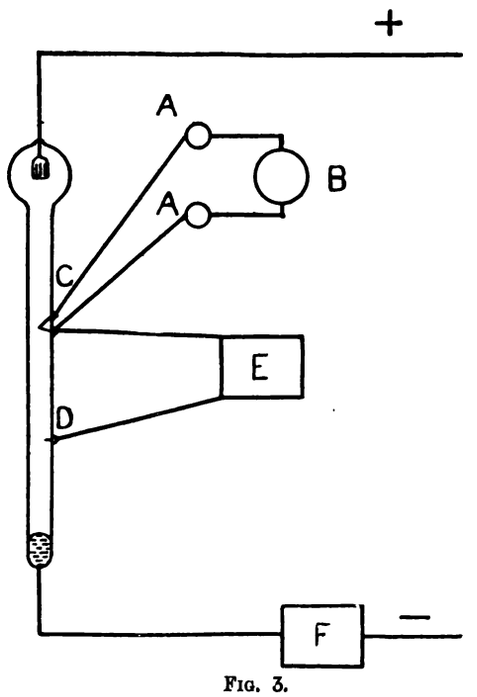

FIG. 3.

the surrounding atmosphere as well as by the voltage variations in the circuit. In consequence, the strength of the light varied considerably, and the lamp went out and could not be easily started again. This could have been corrected by the use of large resistances, but the commercial efficiency of the lamp would have been greatly reduced. Cooper Hewitt paid particular attention to the construction of a lamp which could be highly efficient and burn steadily with a very small resistance in circuit. He found that it was necessary to maintain the vapour at a fairly constant degree of density, and effected this by adding a cooling chamber of suitable dimensions to the lamp. The cooling chamber operates at the condenser for the disintegrated mercury and influences at the same time the density of the vapour. As the conductivity of the vapour is dependent on the density, the condensing or cooling chamber plays a very important rôle in the lamp.

The curve (Fig. 2) is that of an ordinary 50-volt lamp, such as is used when two are run in series on a 110-volt circuit. The efficiency of the lamp is highest when the current amounts to about three to four amperes. But apart from this, it is important to regulate the lamps for this current, as they are less affected by variations of the supply voltage or by the temperature changes of the surrounding air. If the lamps are used with excessive current, there is a visible contraction of the luminous column. This is also noticeable (with large lamps) when the current decreases. In fact, the section of the luminous vapour column increases when the current increases, and decreases when the density increases. If proper terminals are provided, the current can be increased until the high temperature melts the glass.

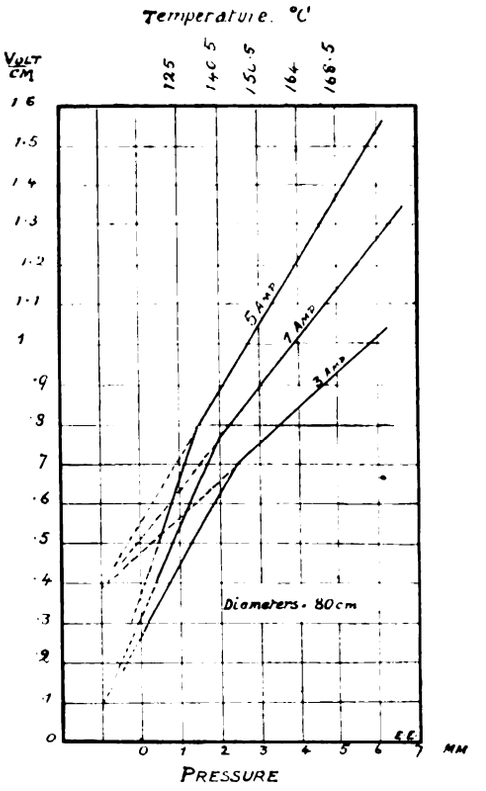

FIG. 4.

In order to determine the influence of density on conductivity, Cooper Hewitt made, with the assistance of A. P. Wills, the following experiment: A lamp was placed in an equally-heated air-bath, the temperature of which was then varied until the vapour in the lamp reached the desired density. The current was switched on, and simultaneously the drop of voltage between the point D and C (Fig 3) measured. In order to avoid new "negative electrodes," this measurement had to be made by means of a static voltmeter, E. All the experiments showed that the vapour density did not immediately change under the influence of the electric current; in fact, there was sufficient time to measure the drop of voltage in the vapour which had been produced by the air-bath. The pressure—*i.e.*, the density of the mercury vapour—was obtained from tables, and they were found to correspond with the temperature readings of the lamp and air-bath, which were measured by thermometer at C and galvanometer at B. The readings indicated that the pressure per centimetre was directly proportional to the density of the vapour, and inversely proportional to the diameter of the tube. With a given density vapour and given current the section of the luminous column assumes a certain dimension, which decreases as the density increases. The curve (Fig. 4) shows the pressure in volts per centimetre with different vapour pressures and different currents. With smaller tubes similar curves are

Digitized by Google

obtained, with the exception that the rise is steeper and the curves come somewhat higher. It is evident that for vapour pressures above ½mm. the curve of voltage per centimetre and of vapour pressure is represented by two straight lines forming an obtuse angle. The position of this point of intersection is dependent on the diameter of the tube and also on the current. The pressure at this point is

$$\Delta_q = \frac{\sqrt{J}}{\sqrt{D}} \text{ approximately,}$$

where J = amperes,
D = diameter in centimetres.

From this point onwards the walls of the tube do not seem to affect the section of the vapour column. But, as previously mentioned, the diameter of the luminous column decreases as the pressure increases. The accompanying curves (Fig. 4) shows the relation between the volts per centimetre and the current with 1mm. pressure. It indicates clearly that by increasing the current the conductivity is also increased. Probably the explanation of this is that by increasing the current more heat is produced in the vapour column. The heat drives some of the vapour out out the column, and increases thereby the conductivity of the latter. It is, of course, assumed that there is sufficient space in the lamp to hold those particles of vapour which are not acted upon by the current. The next curve shows the relation between the voltage per centimetre and the diameter of the tube, the pressure remaining the same—namely, 1mm. From this curve it can be seen that the effect of the walls of the tube on the section of the luminous column is greater with tubes of small diameters than with those of large diameters. Although these laws which Hewitt has discovered apply only to the mercury vapour, it is more than probable that they will also hold good for other vapours.

It is not the purpose of this article to deal with the actual application of the Cooper Hewitt lamp. Photographers and lithographers have found that, instead of using 25 to 50 amperes with arc lamps, they only need about three amperes with the Cooper Hewitt lamp, and at the same time can obtain better results on account of the light being so evenly distributed all over the tube. The diffusion of the light and the absence of red rays, which are well known to fatigue the eyes, make the lamp especially suitable for machine shops and drawing offices. The Cooper Hewitt Electric Company (represented in this country by the British Westinghouse Company) supply lamps for general illumination or for special purposes.

NOTES ON AERIAL POWER LINES.

BY CHE.

The probable introduction of overhead high-tension power transmission lines in this country brings into prominence the necessity for the consideration of several important factors in the design and construction of aerial lines, with which very few engineers have had experience, and in these notes it is proposed to consider the problems underlying the elementary principles of the construction of line wires and their supports.

Obviously, the supports and lines are subjected to various stresses for which provision must be made when designing the same. These stresses are: (1) stresses due to the weight of the conductors and any accidental overload, such as accumulation of snow and ice; and (2) stresses due to the lateral pressure of the wind on the poles and wires. In addition to these stresses, the poles are more or less affected by the effects of vibration.

Dealing with the design of the poles first, and considering only poles of wood, it is clear that the former stresses introduce a compressive or crushing force, whilst the tension in the wire due to its weight and sag, as well as the wind pressure, introduce a flexing strain. If the pole is sufficiently strong to withstand the flexing stress, there is not much danger due to the compressive or crushing force, especially as a very large factor of safety is introduced. Then, again, when the track is a straight line and the spans are equal in length, the longitudinal tensions on any support balance each other, so that the poles have only to resist the weight of the wire and the wind pressure. It is also clear, from first principles, that a pole subjected to a horizontal force tends to bend in the direction of the force, one side being in compression whilst the other side is in tension. In practice the shape of the pole is that of a truncated cone, and it may be shown that the taper for a conical pole to satisfy ordinary working conditions should have the relation

$$d_2 = \tfrac{3}{2} d_1,$$

in which d_1 and d_2 are the diameters of the top and bottom of the pole. If the diameter of the pole at the point of application of force is equal or greater than two-thirds of the diameter of the pole at the surface of the ground, the point of rupture would occur at the surface of the ground, whilst if the diameter at the bottom of the pole is less than $\frac{3}{2}$ times the diameter at the top, the pole will tend to break above the ground line, and be inferior to the strength indicated by the diameter at the top of the pole.

In dealing with the forces acting on the pole, it is best to treat the problem as if the pole were a beam fixed at one end and loaded at the other, and if

I = the moment of inertia of the section $= \frac{\pi d_2^4}{64}$;
T_1 = resistance to rupture per unit section of the material;
h = height of the point of application above the ground;
c = distance from the centre to the fibre under maximum stress $= \frac{1}{2} d_2 = r$ (radius);
F = the horizontal force or the resultant tension in the wires which a pole will support at the instant of rupture, when it occurs at the ground level;

the moment of resistance, M, is given by

$$M = \frac{T_1 I}{c} = \frac{T_1 \frac{\pi d_2^4}{64}}{\frac{1}{2} d_2} = \frac{\pi d_2^3 T_1}{32} = \cdot 7854\, r_2^3\, T_1.$$

The moment of the force applied is

$$M = F h$$

$$\therefore F h = \cdot 7854\, r_2^3\, T_1$$

and $$F = \frac{\frac{\pi}{4} r_2^3 T_1}{h} \text{ or } \frac{\pi d_2^3 T_1}{32 h}$$

and $$T_1 = \frac{4 F h}{\pi r_2^3} \text{ or } \frac{32 F h}{\pi d_2^3}$$

and $$d_2 = \sqrt[3]{\frac{32 F h}{\pi T_1}} = \sqrt[3]{\frac{10{\cdot}18 F h}{T_1}}.$$

The generally accepted values of the tensile strengths, T_1, for the woods most commonly used for poles are as follows: chestnut, 7,000lb. to 13,000lb.; cedar, 11,500lb.; yellow pine, 5,000lb. to 12,000lb.; redwood 11,000lb. In practice only a fraction of these values are taken, so that in the above formulæ $\frac{1}{n} T_1$ should be substituted for T_1, and n, which is the "factor of safety," is usually taken as 10. We thus have for working values of F, T_1, and d_2

$$F = 0{\cdot}00982 \frac{d_2^3 T_1}{h}$$

$$T_1 = \frac{101{\cdot}8 F h}{d_2^3}$$

$$d_2 = \sqrt[3]{\frac{101{\cdot}8 F h}{T_1}}.$$

For corner posts, as when there is a change in the direction of the line—*i e*, when the track is not a straight one—the resultant of the line tensions is not zero, and an additional force is introduced tending to deflect the post, the magnitude and direction of which are readily determined by application of the principle of the parallelogram of forces. Also, when two adjacent spans are not of equal lengths, although the track is a straight one, there is an unbalanced tension. The graphical solution in the case of corner posts is given in Fig. 1, in which O R is the resultant of the equal but inclined tensions, O A and O B or T_2, and if θ be the

Digitized by Google

supplement of the angle contained by the wires we have—

$$OR = T_2 \frac{\sin\theta}{\sin\frac{180-\theta}{2}}$$

$$= T_2 \frac{2\sin\frac{\theta}{2}\cos\frac{\theta}{2}}{\cos\frac{\theta}{2}}$$

$$= 2\,T_2 \sin\frac{\theta}{2}.$$

To counterbalance this effort, the pole must be either stiff enough to stand the bending moment, or else the top of the pole must be anchored in an opposite direction to the resultant stress by means of a guy-wire or rod. If the track is on a slope, so that there is a difference of level between the two supports of a span, there will also be an unbalanced tension to take into account. Should a wire on one side of a post become ruptured, an additional tension is introduced on the other side.

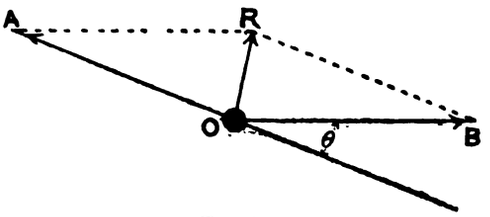

FIG. 1.

The Board of Trade regulations (Clause 17) for securing the safety of the public under the Electric Lighting Acts, 1882 and 1888, set forth that "Every support for an aerial line shall be of a durable material and properly stayed against forces due to wind pressure, change of direction of the line, or unequal length of span. The factor of safety shall be for aerial lines and suspending wires at least 6, and for other parts of the structure at least 12, taking the maximum possible wind pressure at 50lb. per square foot. No addition need be made for a possible accumulation of snow."

Dealing with the tension of aerial wires, it is well known that when a wire is stretched between two points, A and B (Fig. 2), situated at the same level, the curve A D B, known as the catenary, is formed, and the horizontal distance, A B, is termed the *span*, while the vertical distance, C D, between the lowest point of the curve and the horizontal line, A B, is the *deflection*.

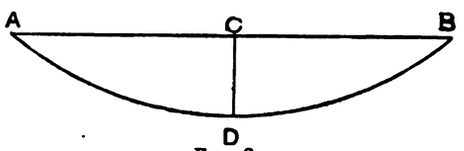

FIG. 2.

Let l = distance between the supports;
s = the sag at a standard temperature;
L = actual length of the wire at the standard temperature;
w = weight of unit length of the wire at the standard temperature;
w_s = weight of snow per unit length of the wire;
θ = standard temperature in degrees C.;
F = horizontal tension of the conductors at the standard temperature at the centre of the span;
d = diameter of the bare wire;
α = coefficient of expansion of the wire per degree C.;
n = factor of safety;
F_u = ultimate tensile strength of the wire.

Then from the properties of the catenary we have, to a close approximation, for ordinary conditions

$$s = \frac{l^2 w}{8F} \quad . \quad . \quad . \quad (1) \qquad F = \frac{l^2 w}{8s} \quad . \quad . \quad . \quad (2)$$

$$L = l + \frac{8s^2}{3l} \text{ or } \frac{L}{l} = 1 + \frac{8}{3}\frac{s^2}{l^2} \quad . \quad . \quad (3)$$

the ratio $\frac{s}{l}$ being the *ratio of deflection*.

Combining equations (1) and (3) we have

$$L = l\left(1 + \frac{l^2 w^2}{24\,F^2}\right) \quad . \quad . \quad . \quad . \quad (4)$$

The tension at either support is given by the equation

$$F_s = F + ws \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

in which ws is a quantity equal to the weight of the wire for a length s equal to the deflection; except in cases, however, where the deflection is very great, F_s does not sensibly differ from the horizontal tension, F, at the lowest point, and no serious error would be introduced by using F instead of F_s. Now, equation (5) may be written

$$F_s = \frac{l^2 w}{8s} + ws = wl\left(\frac{1}{8}\cdot\frac{l}{s} + \frac{s}{l}\right) \quad . \quad . \quad (6)$$

If we denote $\left(\frac{1}{8}\cdot\frac{l}{s} + \frac{s}{l}\right)$ by k, then $F_s = wlk$; wl is obviously the total weight of a wire equal to the span in length, and k consequently denotes the *tension per unit span weight*. k may be obtained experimentally for all ordinary proportionate deflections, and from a curve plotted from these results the total tension at the supports and sags may be determined for all practical cases. Introducing the factor of safety, n, and the ultimate tensile strength of the wire, F_u, we have

$$wlk = F_s = \frac{F_u}{n} \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

but F_u may be expressed as c times the weight of the wire used, consequently

$$wlk = \frac{F_u}{n} = \frac{c \times 5{,}280\,w}{n} \quad . \quad . \quad . \quad . \quad (8)$$

If w is the weight per foot, and l in the above equations is given in feet, therefore

$$nlk = 5{,}280\,c \quad . \quad . \quad . \quad . \quad . \quad (9)$$

but if the mile be the unit of length in the above equations,

$$nk = c \times \frac{1}{l} \text{ or } n = \frac{c}{k} \times \frac{1}{l} \quad . \quad . \quad . \quad (10)$$

in which $\frac{1}{l}$ = number of poles per mile. Equation (10) is a simple relationship connecting the factor of safety, the tensile strength and density of the material, the value of k, and the number of poles per mile. The weights of one mile of copper and aluminium one square inch cross-section are respectively 20,371·878lb. and 6,178·54lb., so that if the tensile strength of a given wire be known, c is readily determined.

Coming to the question of wind pressure, one is met with some very contradictory results made by different investigators. Semenza, for instance, gives the maximum effort due to the wind as 280 kg. per square metre of plane surface, and the effective surface of the wire as its length multiplied by half of its diameter. He also gives the formula

$$P = 3 \times 10^{-5}\, d\, v^2,$$

in which P = kilogrammes per centimetre length, d = diameter of the wire in centimetres, and v = velocity of the wind in metres per second, as being more nearly in accordance with observed values. In this country the Board of Trade fix it as 50lb. per square foot, and in no case should be taken at less than 40lb. per square foot. To determine the area of the plane surface acted upon by the wind, it is usual to take the pressure per foot length on a cylindrical surface, whose diameter is d, as being from 0·5 to 0·75 times the pressure due to the wind per foot length on a flat surface of width, d, and as a mean between these two extremes two-thirds of the pressure expressed by the flat surface may be taken as a satisfactory value for cylindrical wires. Since the weight of the wire acts vertically downwards, whilst the wind acts horizontally, the resultant of the weight of the wire and the wind pressure is given by the relation

$$p = \sqrt{p_1^2 + p_2^2},$$

in which p_1 and p_2 denote respectively the forces due to the weight of the wire and the wind pressure.

ARTIFICIAL DRAUGHT FOR BOILER PLANTS.

BY F. H. DAVIES.

Up to a comparatively recent date, artificial draught as a substitute for the chimney in boiler installations was looked upon chiefly as a means for obtaining a higher duty out of fully-loaded steam-raising plant, or as the only possible alternative where æstheticism forbade the erection of a chimney. Now, however, the true facts of the case are daily becoming more fully recognised, and there is a growing tendency among engineers to regard properly-applied artificial draught as a very valuable adjunct for securing both capital and revenue economy. The objects of a draught are to supply the boiler fires with a sufficient quantity of air to allow of proper combustion of the fuel, and to carry off the resultant gases. Setting aside chimney draught, which is foreign to the subject, this may be done in one of three ways, with several variations of each.

Steam Jet.—Perhaps the earliest, and certainly the least efficient, system of artificial draught from the point of view of power consumption, is that known as the steam jet. In its nature it is a somewhat unscientific application, and rather wasteful; it is, however, in large use, and under certain conditions, despite its failings, appears to be doing good work. In principle it is very simple. The ashpit of the boiler is closed by an airtight door, and the steam jet is conducted to the underneath side of the furnace through properly-shaped nozzles. By the aid of a simple injector arrangement the steam in its flow is allowed to draw in a certain quantity of air, and the two together create a pressure in the ashpit higher than that of the atmosphere. The result is a draught through the fires, which may be regulated in intensity by the aid of valves in the steam and air pipes. The system has this to commend it: it is simple, very convenient, and decidedly the cheapest to instal; in addition, it is credited with preventing the formation of clinker to a certain degree by keeping the bars cool. On the other hand, there is much to be said against it—enough to put it beyond consideration in many cases. Unless the jets are most carefully distributed they are apt to cause excessive centralised heat in places on the firebars, with resultant burning of the latter; and if the steam is at all wet, the boiler will probably suffer harm. The great charge against the steam jet, however, is its wastefulness as compared with any other form of artificial draught producer. Under the most favourable conditions it will absorb approximately 3 to 5 per cent. of the total steam generated by the boiler to which it is attached; and in bad cases this amount may be increased to 10 or even 20 per cent. The steam jet may thus be looked upon as undesirable in any installation where high-priced fuel is used and economy is a desideratum. Only in situations where fuel may be obtained at an almost nominal figure, or where refuse is to be destroyed by the aid of forced draught, should it receive consideration, and then chiefly because of its low initial cost. Furnaces fitted with this type of forced draught have been proved capable of burning coal of the lowest calorific value and dust which in the ordinary way would be quite useless.

Mechanical Draught.—Mechanical draught has many advantages over what is termed the natural draught produced by a chimney. In the first place, the capital outlay is very much less, for although with any artificial draught something in the way of a chimney is necessary to carry off the products of combustion, it need be only comparatively small, and built of steel upon light foundations. Mechanical draught renders the plant entirely independent of atmospheric conditions, which have a very marked effect upon the efficiency of a chimney. In addition, it gives the fireman a thorough control over his draught, which, if properly taken advantage of, is of great value in securing high fuel economy. This adaptability to circumstances, which the chimney lacks, means that all classes of fuel, even those of the lowest quality, may be burnt efficiently and thoroughly, and that sudden calls for steam, such as are common in electrical work, may be met with ease by an increase of the draught pressure. Extensions, too, are much simpler and cheaper, as an increase in boiler plant which may be sufficient to overload a chimney calls merely for the installation of another fan. In this connection it should be mentioned that there is in total an economy of floor space, since higher evaporative duty may be obtained from the boilers with artificial than with natural draught. The temperature of the exit gases with chimney draught must not be less than about 400deg. F., as upon the temperature of the gases in the chimney the draught depends. With artificially produced draught this necessity for considerable heat in the chimney is, of course, absent, and consequently the furnace gases may have practically all their heat taken out of them and utilised for economical purposes. Methods of subtracting this heat and turning it to useful account will be dealt with later.

Mechanical Forced Draught.—Mechanical forced draught is obtained by the aid of fans which supply air under pressure to the boiler fires. There are two methods of doing this. That usual in marine practice is to close all air inlets to the stokeholds excepting that through the fan, which, according to the speed at which it is run, maintains the pressure in the stokeholds slightly or largely over that of the atmosphere. At the best of times a ship's funnel is a poor draught producer compared with a land chimney, and hence, if high speed and consequent boiler forcing is a necessity, as in the case of warships, mechanical draught has to be resorted to. On shore it is practically impossible to render a boiler-house airtight, and neither is it necessary, since better results may be secured by closing the ashpits, as in the steam-jet system, and leading the draught into them through special channels, regulated each by dampers.

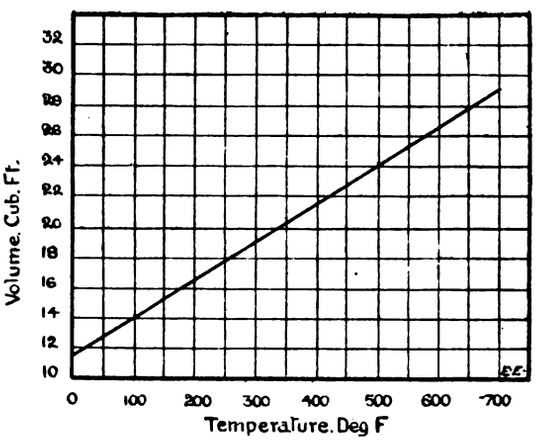

FIG. 1.—Curve showing the Volume of 1lb. of Air at atmospheric pressure at various temperatures.

The Howden system of forced draught is an extremely efficient one, and representative of the best practice. By the arrangement of first passing the air through tubes placed in the path of the furnace gases a large proportion of the heat of the latter is made useful, and the draught, before it is delivered to the fires, attains a temperature of from 150deg. to 170deg. F. The advantages arising from this use of heated air are an increased average furnace temperature, and, therefore, higher evaporation and a smaller excess of air, owing to the facilitated combination of the oxygen with the fire gases. In the Howden system the heated air is supplied both below and above the fires by an arrangement of air-boxes placed on the front of the boilers, and its quantity may be regulated by valves. A closed ashpit is not necessary in this system. The danger of a careless stoker opening the firedoors without first shutting off the draught, and so causing the flames to come out of the front of the boiler with the risk of severe burning, is one which has frequently been advanced as an objection to forced draught. In this system, however, such an occurrence is impossible, as the doors cannot be opened until the draught is completely shut off. A further objection, that forced draught is apt to blow holes in the fire, is easily got over by a careful regulation of its intensity with the thickness of the fire, and a proper distribution of the draught over the incandescent surface.

Induced Draught.—Induced draught is comparable to natural chimney draught, in that it is caused by the maintenance of a lower pressure in the flues than that of the atmosphere. This difference in pressure may at times amount to as much as 4in. of water. With induced draught

Digitized by Google

the fan is situated in the flues or at the base of the chimney, and it is thus exposed to the full heat of the furnace gases, and to the destructive action of the grit that is carried over from the fires. In early days this was considered an almost fatal objection to the system, but experience has proved that although the wear and tear of the fan is certainly greater than in the case of forced draught, there is no

manner in which the power required to run the fan mounts up with the heat of the gases. The induced-draught system lends itself very well to the thermal economy obtained by heating the air prior to its being drawn into the furnace. This is effected in much the same manner as that described above; horizontal or vertical tubes are placed in a favourable position in the flues, and the air passes first through

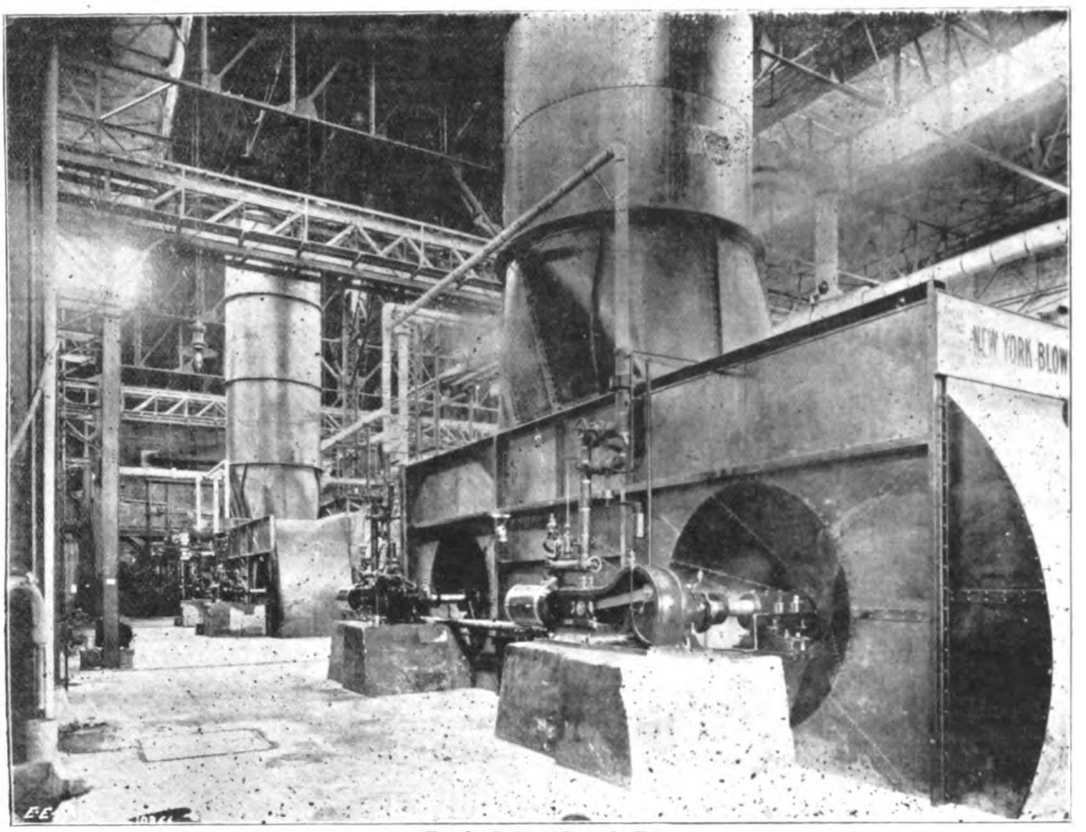

FIG. 2.—Induced Draught Fans.

difficulty whatsoever in successfully working fans in flue gases up to and even exceeding 500deg. F. In the case of all but the smallest installations the fans are always provided with water-cooling gear attached to the bearings, which entirely prevents overheating. An open ashpit is, of course, used with induced draught, which possesses all the advantages of forced draught in the ease and convenience of control. The fan, however, takes rather more power to drive it (from 1 to 2 per cent. of the boiler output), and the system is consequently not quite so economical. The reason of this is that, although the weight of air dealt with is the same as in the case of forced

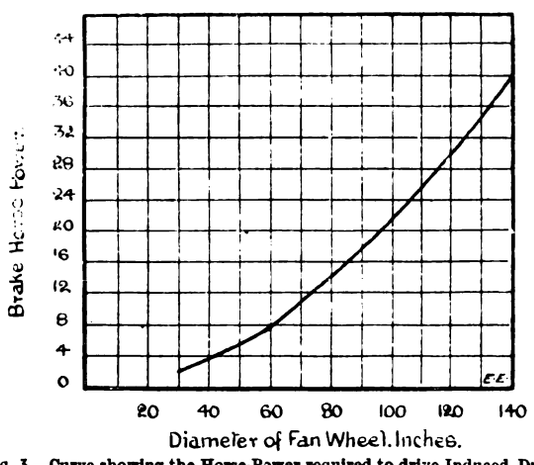

FIG. 3.—Curve showing the Horse-Power required to drive Induced Draught Fans of various sizes in a flue temperature of 550deg. F.

draught, its volume is much greater, due to the fact that it is at a high temperature, and consequently, to remove the same weight of air and to create the same draught, the fan must be larger or must revolve at a quicker speed. The increase in the volume of air with temperature is shown in curve form in Fig. 1, which will convey an idea of the

them before reaching the fires. A good example of an induced-draught installation is shown in Fig. 2. In this case economisers were not installed, as the plant was only a temporary one; their use, however, is highly desirable, not only because of the saving in fuel effected by them, but in order to reduce the temperature of the gases in which the fan works, and, therefore, the power required to operate it.

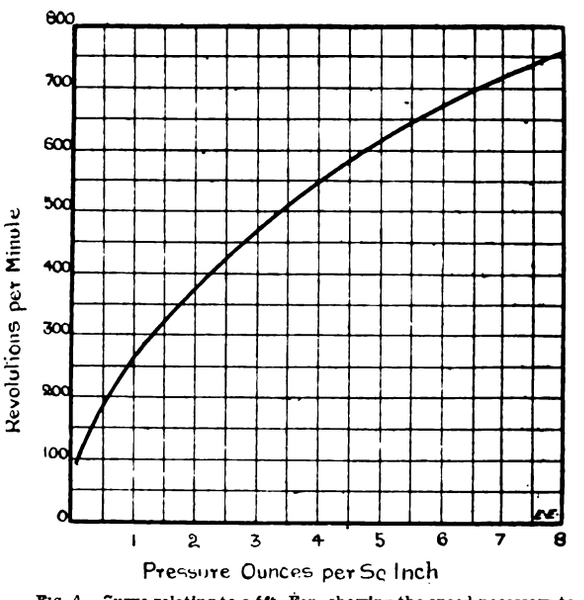

FIG. 4.—Curve relating to a 6ft. Fan, showing the speed necessary to maintain various pressures over a suitable area.

Fans.—The fan being the integral part of all mechanical draught systems, some few details of its nature and operation may not be out of place. There are two classes of fans which may be used for creating a draught—the type something akin to a propeller, which throws the air off in a direction at right angles to the blades, and the centrifugal

Digitized by Google

class, which, drawing the air in at the centre, discharges it at the ends of the blades in a tangential direction. This latter is practically the only form used for the purpose in question; the propeller type may therefore be neglected. The curves shown in Figs. 3 and 4 speak for themselves They are based upon the published figures of the American Blower Company and the Sturtevant Company respectively. The air pressure which any given fan will generate depends upon its peripheral velocity, varying as the square of its speed. The velocity of the air discharge with a free outlet is practically equal to the peripheral velocity of the wheel, and the power absorbed varies as the cube of the speed. It is, therefore, preferable to use large vans at low velocities than small ones running at a high speed. The actual performance of a fan will vary considerably from its theoretical performance with the size and shape of its casing. General rules, therefore, are not of very much practical value for application to every class of fan, and only serve to outline the performance. In the same way the effective draught at the chimney base with any given fan will depend largely upon the nature of the passages provided for the air. If these are small and tortuous they will naturally give rise to a considerable loss, and increase the percentage of the boiler power required by the fans. As a rule, air flues are built of brick, which should be glazed or thoroughly painted to prevent leakage. In some cases, however, iron or earthenware pipes are used, great care being given to their jointing for the above reason. All things being considered, the installation of a fan draught to obtain the best results is by no means a simple matter, and requires a fair amount of special knowledge. This is particularly the case as regards the fan itself, little being known of its relative performance under different circumstances outside the ranks of specialists.

WIRELESS TELEGRAPHY MEASUREMENTS.*

BY W. DUDDELL, MEMBER, AND J. E. TAYLOR, ASSOCIATE MEMBER.

In spite of the very large amount of matter that has been published on the subject of wireless telegraphy, there is very little quantitative data available. The object of the present tests was to measure the R.M.S. value of the current in the receiving air wire and to determine as far as possible how this current depends on the arrangement of the transmitting and receiving apparatus and the distance between them. The following preliminary tests were officially carried out by the authors for the Postal Telegraph Department, at the instance and under the control of the engineer-in-chief, Mr. J. Gavey, C.B., in Bushy Park, in June, 1904. The tests were made between a transmitting station which could be easily and quickly moved to any part of Bushy Park as required and a receiving station which was set up in a fixed position for about one-half of the tests, and was then taken down and reset up in a fresh position and many of the former tests repeated. All the transmitting apparatus was fitted up inside a large Post Office temporary telegraph van, behind the driver's seat of which a bamboo mast was fixed. The vertical wire—a $^{7}/_{22}$ G.P. (cable core)—was suspended from a spar on this mast, and could be raised or lowered as required. The earth connection was made to the centre of a piece of galvanised iron wire netting 76ft. long and 3ft. 10in. wide, fixed flat on the top of the grass alongside of the van.

In all the experiments given in this paper the vertical wire was directly connected to the closed oscillating circuit, as shown in the diagram of connections (Fig. 1). The method of operation is based on the excitation of oscillations in the antenna by directly connecting it to a closed oscillating circuit, some other point of which is connected to earth. There are thus two distinct resonant systems; one a closed circuit, consisting of a condenser and inductance spiral, L, and the other the antenna, inductance spirals, H and L, and the wire netting or surface of the ground. When made to have the same period of electric vibration, oscillations are communicated to the antenna. Adjustment for this purpose was made by altering the self-induction, H, until the current in the air wire was a maximum, as indicated on the thermal ammeter, A. A well-defined maximum was readily obtained in this way, though sharper tuning could have been reached by reducing the amount of coupling between the two resonant systems. It was found, under the conditions of working, that there corresponded to each combination of self-induction and capacity a spark-length which gave the required current in the transmitter air wire. The frequency of the oscillations was altered when required by changing the size and number of the jars used, and the vertical wire was always tuned to suit the oscillating circuit by altering the number of the turns of the self-induction, H, in series with it. This adjustment was made by observing the current by the Duddell thermo-ammeter, A, and adjusting the number of the turns of the self-induction till this current was a maximum. The self-induction, H, consisted of 71 turns made by winding two No. 16 tinned copper wires side by side, touching one another in a shallow screw thread on a wooden cylinder 4in. diameter and 18in. long. The jar or jars, F, were charged by an induction coil, I, through two choking coils, intended to protect the induction coil from the oscillatory currents. The induction coil (a 30cm. spark size instrument) was supplied by 15 accumulators, a resistance being used in series with the coil. Two different interrupters were used: (1) a mercury turbine interrupter; (2) a Grisson interrupter.*

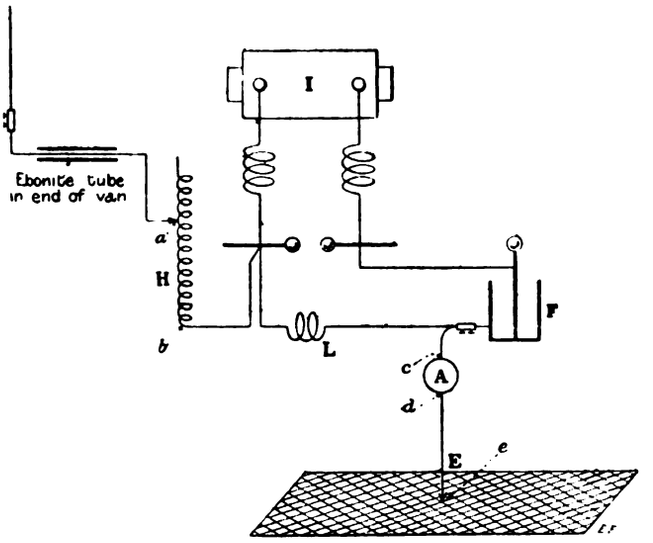

FIG. 1.

The mercury turbine interrupter was driven in all the tests at a speed of 1,070 r.p.m., giving 17·9 trains of oscillations per second; and the latter was run at 1,500 r.p.m, giving about 100 trains of oscillations per second. Signals lasting 30 seconds, with an equal time interval between them, were regularly sent from the transmitter, and during each signal an observation of the current in the vertical receiving wire was made. In general from eight to twelve such observations were taken for each experiment. In most of the tests the height of the top of the vertical transmitting wire from the ground was 42ft., the length of wire from the top to the terminal of the self-induction being 48ft. 6in. The length of the earth connection was 28ft. 4in., and about 4ft. 6in. of wire was used in making the connections between the self-induction, spark-gap, jars, and ammeter inside the van. Three different wave-lengths were used in the tests, obtained by altering

* Paper read before the Institution of Electrical Engineers.

* The Grisson interrupter is used with a special induction coil or transformer having a connection made to the middle point of the primary, so that a current flowing in at this point and dividing equally between the two halves produces no magnetic field. This point is connected to one pole of the battery, the other two terminals being connected alternately with the other pole of the battery by means of a revolving commutator. The following series of actions takes place:

1. Current through first half of primary, magnetising core.
2. ,, ,, both halves, no magnetisation.
3. ,, ,, second half of primary, core oppositely magnetised
4. ,, ,, both halves, no magnetisation.

In action it is necessary to regulate the speed of the commutator so as to produce a resonance between the secondary circuit and the rate of reversal in the primary.

the capacity in the oscillating circuit and tuning the vertical wire to suit. In each case the self-induction, L, in the oscillating circuit, which consisted of two turns of stranded conductor wound on a wood core 127mm. diameter, 7mm. pitch, was kept the same. The stranded conductor consisted of 19 No. 22 copper wires, each separately silk covered.

Wave No. 1.—The capacity, F, consisted of one four-pint jar half covered with tinfoil. Wave-length, about 375ft. With this wave-length and the vertical wire 42ft. high, the following data were always worked to unless stated to the contrary: Spark-length, 5·29mm. Current in vertical wire, about 0·36 ampere with mercury interrupter. Number of turns of self-induction in series with vertical wire, 12

Wave No. 2.—The capacity, F, consisted of one four-pint jar completely covered with tinfoil. Wave-length, about 400ft. With 42ft. vertical wire, unless stated to the contrary, the other data are: Spark-length, 7·08mm. Current in vertical wire, about 0·50 ampere with mercury interrupter. Number of turns of self-induction in series with vertical wire, 18.

variable self-induction the same size as that used in the transmitter circuit (H, Fig. 1), and the other end of this self-induction was connected to earth through a Duddell thermo-galvanometer, which was used to measure the received current. The earth connection was made to the centre of a piece of wire netting 77ft. long by 3ft. 10in. wide. The vertical height of the air wire from the ground was in most of the tests 56ft., the total length of wire from the top to the terminal of the self-induction being 65ft., and the length of the earth connection 19ft. 3in. The receiving circuit was tuned by altering the number of turns in the self-induction until the current as shown by the thermo-galvanometer was a maximum. Observations were generally made both with the circuit tuned as above and also with the air wire connected direct to earth through the thermo-galvanometer without any self-induction in series; this arrangement will be called "untuned." In the thermo-galvanometer the current to be measured flows through a fine resistance about 3mm. long, and the heat given out by it falls on a small thermo-junction fixed to the moving part of the instrument. The sensibility can

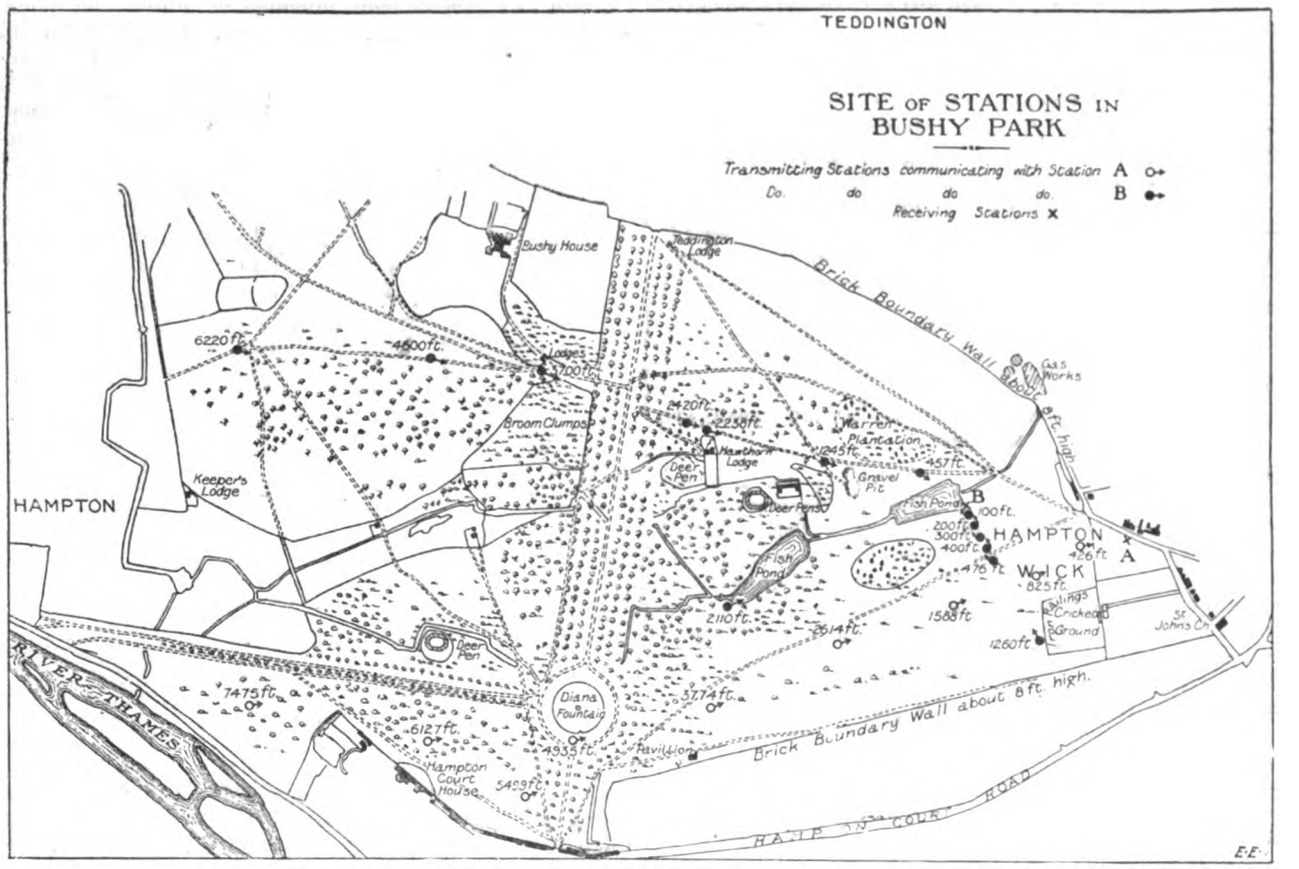

FIG. 2.—Reproduced from the Ordnance Survey Map with the sanction of the Controller of H.M. Stationery Office.

Wave No. 3.—The capacity, F, consisted of two four-pint jars completely covered with tinfoil used in parallel. Wave-length, about 500ft. With 42ft. vertical wire, unless stated to the contrary, the other data are: Spark-length, 4·55mm. Current in vertical wire, about 0·50 ampere with mercury interrupter. Current in vertical wire, about 0·70 ampere with Grisson interrupter. Number of turns of self-induction in series with vertical wire, 40.

The receiver was first set up in a paddock at the point marked A on the accompanying map (Fig. 2). The vertical wire was suspended from a spar fixed to the top of a terminal pole belonging to the telephone system; the overhead telephone wires ended at this pole, and were taken down the side of the pole and under the park in a cable. The terminal pole was stayed with stout stranded iron wire. To make certain what effect these telephone wires and stays were having on the results, the receiver was moved to point B on the map (Fig. 2), near the fishponds. In this position the vertical wire was hung from a light bamboo tied to the top of a London County Council fire-escape. The receiving instruments were, in each case, set up inside a small wooden contractor's office. The vertical air wire—a $^{7}/_{22}$ G.P. (cable core)—was connected to a

be altered either by varying the resistance of the heater or by altering the distance between the heater and the thermo-junction. The resistance of the heaters used was about 100 ohms, and the sensibility was adjusted by changing the distance between the heater and the thermo-junction, so that throughout each series of tests both the resistance and the lengths of wire used in the measuring circuit remained constant.

Height of Transmitting Air Wire Varied.—Three different lengths of wire were used so as to make the vertical height of the transmitting air wire 21ft., 31·5ft., and 42ft. The arrangement of the closed oscillating circuit, and consequently its own frequency of oscillation, was not altered: the air wire being retuned to the same frequency as the oscillating circuit by altering the number of turns of the self-induction in series with it. When the height of the air wire is increased, we may keep the power supplied to the coil and the length of the spark-gap constant, in which case the current in the air wire will also increase though not in the same proportion; or we can keep this current constant by altering the spark-gap and the power supplied to the coil. Both these arrangements were tested. The results are given in Table I. The tests were repeated with

Digitized by Google

two different wave-lengths. Of course, during the tests the arrangements at the receiver end were kept constant. Taking first the figures for the receiver tuned to the same frequency as the transmitter, and the current in the transmitter air wire kept approximately constant, it is seen that the receiver current is very closely proportioned to the height of the transmitter air wire. In the results, where both the height and the current in the transmitter air wire varied (spark-length constant) the received current is nearly proportional to the product of the height into the current in the transmitter. So that calling the vertical height of the transmitter air wire h, and the current flowing into it A, we may write the received current, in micro-amperes, $k\,h$ A, where k is a constant which has the value 16·6 for wave No. 1 and 20 for wave No. 2, h being in feet and A in amperes. Using these two constants, a column of calculated currents has been worked out for comparison with the observed values. Turning next to the results with the plain air-wire receiver (untuned), it is not possible to find values for the constant k which will fit the results at all satisfactorily. The nearest values are $k = 5{\cdot}3$ for wave No. 3, and 16·7 for wave No. 1. These observations require to be extended on a larger scale before it can be said what the exact relation is between the height of the transmitting antenna and the current in the receiving air wire, though it appears to tend towards a simple ratio.

42	12	5·39	0·355	308	298	270·5	248·5

Arrangement of Transmitter Air Wire Varied.—The results obtained are given in Table II. The main point to be noted is that, taking a constant length of transmitter air wire and reducing its vertical height to one-half, by rolling up half of it at the top, or by carrying it out horizontally for half its length and then fixing the remainder vertical, or by forming a vertical loop, the current in the receiving air wire is reduced to approximately one-half the value it has for the whole transmitter wire vertical. So that reducing the vertical height by any of these methods has the same effect as cutting off the wire from the top as found in last section. Taking the air wire having a vertical height of 21ft., we have found that if an additional 21ft. be added to the top so as to make the vertical height 42ft. the received current is doubled; if, however, the extra 21ft. be added horizontally to the top, so as not to increase the vertical height, the received current is still increased by 50 per cent. Thus an air wire 21ft. high with 20ft. of wire connected to it in a horizontal position at the top produced more current in the receiver than an air wire 31ft. 6in. high.

Earth Connections Varied.—In all the tests given in this reports, except those detailed in this section, the earth connection at each station consisted of about 76ft. of wire netting flat on the grass. The tests given in Table III. show that only the centre part of the netting near where the earth wire was fixed to it was effective, the two extreme ends of the netting appear to make no appreciable effect on the result. This seems to indicate that it would be better to use a circular piece of netting for the earth with the wire connected to the centre rather than a long strip, as was used in these experiments. An attempt was made to obtain a better earth by connecting the earth wire to the lead sheathing of the telephone cable, which is under the park, but the received current with this connection was only about 60 per cent. of that obtained with the netting earth. This telephone cable is armoured and laid direct in the earth. An earth was also made on the iron stay of the terminal pole, and a slightly better result obtained than with the connection to the lead sheath of the cable. The question of the earth connection for wireless telegraphy is a most important one, and requires very thorough investigation. It was several times noticed that the current into the transmitter air wire was slightly diminished at the commencement of a shower of rain. Thus, after the weather had been dry for about a week, a heavy rainstorm reduced the current by about 2 per cent. This appeared to be due to altering the conditions of the earth rather than to any effect on the air wire. Retuning did not reproduce the original current.

TABLE II.—Arrangement of Transmitter Air Wire Varied. Receiver in paddock, distance 1.588ft. Height of receiver air wire, 56ft. Spark-gap, 4·55mm. Mercury interrupter. Wave No. 3 (500ft.).

Bound Volumes of "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold-Lettered, price 8s. 6d. New Volume, January to June, 1905, now ready.*

THE TELEPHONIC QUESTION.

Most people are utterly tired of the telephonic question, as indeed we are, but it is necessary for the sake of historic continuity to refer to the action of the House of Commons on Mr. Lough's motion relating to the agreement. We presume the discussion in the House of Commons was necessary in order that the Postmaster-General might have the opportunity of saying that practically he accepted the suggestions of the committee as far as they could be accepted. He pointed out that there were two parties to an agreement, and modifications could not be made unless with the consent of both parties. In our last issue we stated that the suggestions of the committee with regard to the employés to be taken over were satisfactory. They have been accepted by the Postmaster-General with certain necessary modifications to make them workable. It will be well, perhaps, to put on record in these pages the terms as read by Lord Stanley in the discussion. They were as follows: (1) "Subject to the other provisions of this memorandum the Postmaster-General will take into the service of the Post Office the servants and officers of the company who have been not less than two years continuously in the service of the company on Dec. 31, 1911, and such officers and servants shall enjoy the advantages and be subject to all the conditions of the rank or grade to which they are admitted in the same manner as other officers and servants of the Post Office in that rank or grade. This undertaking does not apply to the general manager or to officers of the company in receipt of £700 per annum or upwards. (2) The Postmaster-General has already by his agreement with the company conceded that officers or servants who have been continuously in the service of the company from Aug. 15, 1904, until Dec. 31, 1911, and who then became established servants of the Post Office, entitled to pension, shall be so entitled, though they may retire before they have served ten years under the Crown. (3) He is also willing, in the case of officers who do not participate in the pension scheme of the National Telephone Company, and who on the transfer of the company's business become established servants of the Post Office entitled to pension, to allow them to count for purposes of pension their continuous service with the company subsequent to Dec. 31, 1909, as service under the Crown. (4) As regards medical examination, the Postmaster-General cannot undertake to examine candidates for the Telephone Company's service, but he is willing to dispense in 1912 with the medical examination of any officer or servant, if such officer or servant has been in the service of the company continuously for two years on Dec. 31, 1911, and has had no abnormal amount of sick leave during that time. (5) The pension fund of the company is in the hands of trustees, and its administration depends upon a private trust deed. The provisions of the deed are so different from the conditions of the Civil Service pension system that (apart from other difficulties) it would be impracticable for the Postmaster-General to administer the fund or to continue the same system for individuals. For instance, under the trust deed no pension can be granted to an officer who retires under the age of sixty-five, whereas under the rules of the Civil Service an officer may be called upon to retire at sixty, and if retiring at sixty, either compulsorily or voluntarily, is entitled to a pension. The fund must, therefore, be closed, and officers and servants entering the Post Office must be subject to the Civil Service rules as to pensions (subject to the provisions of this memorandum) If, however, it be shown that by the closing of the company's pension fund and the substitution of the system of Civil Service superannuation the general

Digitized by Google

body of the participants in the pension scheme of the company will be placed in a substantially less favourable position, the Postmaster-General will consider the expediency of adding a period (not exceeding in any case two years) to the service which under the rules of the Civil Service the officers affected are entitled to count for purposes of pension. (6) These arrangements cannot be fully carried out without the authority of an Act of Parliament, and this declaration is made subject to the passing of such an Act. An Act will be necessary to provide the money for the purchase from the company, and provisions on this subject will be included in that measure." The only other point to be mentioned is that the Postmaster-General was emphatic against granting any more licenses before 1911 to municipalities, because the National naturally would not give way on the question of time extension of its privilege to run correspondingly with the time such licenses would run. He said: "The committee urged that no corresponding extension should be granted to the company. The company would not agree to that, and he was bound to say he thought their refusal was justified. What were the circumstances? The agreement of the Act of 1898 was that, when a municipality obtained a license, and was in competition with the National Telephone Company, a license extending to the same period should be granted to the company. It was the late Mr. Hanbury, who was always quoted as a friend of the municipalities, who imposed this condition. The proposal of the committee was a practical infringement of a statutory right. There was a further condition—that there should be intercommunication at once and without charge between the municipalities to whom was granted a license and the company. That meant that if the company had worked up a business of, say, three hundred subscribers in a town, a municipality entering the field would at once enjoy the advantage of having those three hundred members, not indeed as subscribers, but as communicants. He thought that a most unfair condition, and he was not surprised that the company would not agree to it. If the House insisted on that condition, the agreement fell to the ground. If the hon. member's motion were carried, the agreement would cease to exist. He thought hon. members ought to think twice before they sacrificed the advantages that would come from the agreement." In the end Mr. Lough's motion was lost by a majority of seventy-seven. We thus come to the position that this agreement, with the modifications accepted by both parties, will hold; that no more municipal licenses will be granted; and that in 1911 the telephonic system of the country reverts to the State on what are known as tramway terms, and that due consideration is given to the employés existing at the time of the take over.

THE POST OFFICE REPORT.

The fifty-first annual report of the Postmaster-General has just been issued, and deals with the business of the year ending March 31, 1905. With the development of the postal business we are not concerned editorially, but the results show a steady increase both in the public services rendered and financial returns. Considerable extensions have been made in the use of motor vans for the conveyance of mails, and Lord Stanley is able to report a substantial advance in the reliability of the services already established. On some services the results have been highly satisfactory, but on others the motor vans employed have not yet shown themselves to be so trustworthy as horse vans. The use of such motor vans is being extended.

The returns of the Telegraph Department show that during the year ended March 31, 1905, 88,969,000 telegrams passed over the Post Office wires, as against 89,997,000 in 1903-4, a decrease of 1·14 per cent. The decrease in private telegrams was over 1¾ million messages. The decrease in the number of ordinary inland telegrams is perhaps due partly to trade depression; but as it is coupled with an increase of 5·1 per cent. in the foreign telegrams, it may be attributed largely to the growth of the telephone system. The number of foreign telegrams is the highest on record. The average number of words per week in Press telegrams during the year was 15,531,332, against 14,588,458 in 1903-4. During the year 193 new telegraph offices have been opened in country villages and the suburbs of the large towns. Guarantees have been given for 154 of these new offices—66 by local authorities and 88 by private persons. The telegraph offices now open in the United Kingdom number 10,172 at post offices and 2,354 at railway stations and other public places. The delivery of telegrams by cycle instead of foot messengers has been further extended, and 3,898 bicycles are now employed for this purpose. About 150 bicycles have been issued for the use of linemen engaged in the maintenance of the telegraph lines.

The system of providing direct communication between provincial towns has been pursued as in previous years. Amongst other direct lines may be mentioned new circuits between Manchester and Southampton, Dublin and Cardiff, Liverpool and Waterford, Liverpool and Londonderry, Birmingham and Cork, and Preston and Glasgow. Cambridge has been placed in direct communication with Ipswich, Norwich, and Peterborough; and the communications in the Eastern Counties have generally been improved. The underground line from London to the North has been extended, as foreshadowed in the last report, by the provision of a cable containing 97 wires between Warrington and Carlisle, and the laying of 76 miles of pipe, which, together with the section laid in the previous year over the Beattock incline, complete the pipe line from Carlisle to Glasgow. It is proposed this year to provide wires over the latter section, and communication will then be possible between London and Glasgow by means of underground wires solely. The next extension of the underground trunk telegraphs is to be the establishment of underground communication with the West of England. A pipe is being laid to contain 137 wires between Hanwell and Slough, and during the present year it will be extended from Slough to Reading. The provision of a pipe and cable between London and Chatham is also being put in hand as a beginning of an underground route to the south east coast, the point of departure of many of the submarine cables. The use of pneumatic tubes laid under the streets for the conveyance of telegrams between the head and branch offices in large towns is being gradually increased. Tubes have recently been provided at Edinburgh, Belfast, and Southampton, and it is proposed to serve several of the West-end branch offices in London by this means upon the completion of the new power station at Blackfriars, from which they will be worked.

On the vexed question of wayleaves Lord Stanley says: "It is my constant endeavour to minimise the inconvenience which my works must inevitably cause to those who use the streets under which telegraphs are being laid, and I am convinced that my officers zealously second my efforts in this respect. I think also that I go no further than is absolutely necessary in erecting overhead telegraphs along the country roads, though I am aware that in this matter also my action is in some quarters unwelcome. I am bound to emphasise the fact that, in the present state of electrical science, I cannot maintain an efficient telephone service over long distances without keeping the wires overhead; and I cannot even in the case of telephone exchange wires set up an adequate system in the suburbs and the country at any reasonable cost if I am to carry isolated lines underground. I regret to note increasing objections both from certain local authorities and from private landowners to the necessary extensions of my lines. Appeal was made during the last year on four occasions to the courts, two of the cases being further referred to the Railway and Canal Commission. In each case the final decision was in favour

Digitized by Google

of my department. The necessity for these proceedings frequently delays the connection of subscribers with the Post Office telephone exchanges."

Promising experiments with various high-speed automatic type-writing telegraphs are being continued at the Post Office. The Postmaster-General remarks that British makers of electric plant are now devoting more of their attention than formerly to the manufacture of telephone apparatus, though he cannot yet dispense—or nearly dispense—with the services of foreign makers. As regard foreign telegraphs, a small direct line is to be provided between London and Cologne, and also between London and St. Malo. The cable about to be laid to Iceland *vid* the Faroe Islands is also referred to in the report.

On the question of wireless telegraphy, the report states that some difficulty has been experienced in dealing with the applications for commercial licenses, owing to the fact that, in the present state of electrical science, it is impossible for the stations of rival undertakings to work in the same neighbourhood without danger of mutual interference. During the interruption of the cable to the Scilly Islands in March last communication was restored by means of wireless telegraphy between the Admiralty station on the island and the Marconi Company's station at Poldhu; and arrangements have been made for utilising the service in any future case of interruption. The international conference on wireless telegraphy, which was to have been held in April last, was postponed owing to the political situation.

As regards telephones, the number of trunk wire centres open on March 31 last was 443, an increase of 47 in the year. The new trunk circuits provided during the year numbered 186, and the total number in use was 1,604, as compared with 1,418 in the preceding year. The total length of the trunk circuits in use was 56,400 miles, containing about 112,800 miles of wire. The capital expenditure on the purchase and development of the trunk wire system up to March 31 last was £2,537,288 including an expenditure during the year of £337,246. The conversations over trunk lines by telephone totalled nearly 15½ millions, and the increase was nearly two millions, which is more than the decrease in private telegrams. The average value of each conversation was 5·9d.—just under the cost of one telegram.

Last year the Anglo-French telephone service was extended to the principal provincial towns in England and France. The service has since been extended to certain other English provincial towns, and the Anglo-Belgian telephone service has similarly been extended during the year. There are now four circuits between London and Paris, one between London and Lille, and two between London and Brussels, the latter carrying an increasing amount of traffic. A still further development of these services may be expected now the new agreement with the National Telephone Company has been approved by Parliament, as under that agreement the lines will become available for use by subscribers to the company's system. Experiments have recently been made in telephonic communication between London and Rome by way of Paris. It was found possible to exchange speech when the conditions were exceptionally favourable; but, in spite of the partial success of the experiment, a public service between the two capitals is not at present practicable. No less than 75 small telephone exchanges have been opened by the Post Office during the year, most of which are in places where no telephone service was previously available.

The number of telephones in connection with the Post Office London telephone system increased during the year from 15,632 to 24,351, and additional subscribers are being connected at an average rate of about 150 a week. A new exchange was opened at Hampstead during the year under review, and two others have been opened since March 31. The accommodation at the Central Exchange is now almost exhausted, but a new exchange, to be called the City Exchange, with a maximum capacity of 18,000 lines, is expected to be ready for opening in a few months. The length of the underground pipes which had been laid in the London area on March 31 last was 1,251 miles, 105 miles having been laid during the year. Cables containing 162,216 miles of wire have been provided, including 35,572 miles rented by the National Telephone Company pending the transfer of the company's system to the Post Office. The lines of the present subscribers and the junction lines between exchanges have absorbed 66,821 miles, and 59,823 miles of wire remain available for the future development of the London telephone system.

The average cost of construction per mile of double wire has decreased since last year from £18. 16s. 10d. to £16. 18s. 6d., and the average cost of constructing an exchange circuit (including the installation of telephone instruments and of exchange apparatus, but excluding the provision of spare plant) has been £38. 18s. 9d., as against £41. 9s. 8d. in the previous year. Taking into account the whole system, including spare plant of all kinds, the capital expenditure per station—*i.e.*, per telephone connected with an exchange—stands now at £64, as compared with £86 in 1902-3, and £73 in 1903-4. It is hoped that the expenditure per station will still further diminish as the very large amount of spare plant provided comes into use.

An account of the receipts and expenditure relating to the London service for the year ended March 31, 1905, shows a balance of £93,298, a sum nearly sufficient to meet the charge for interest on capital and to provide for depreciation of plant. This balance is rapidly increasing as more of the plant comes into use and begins to earn revenue.

The report, on the whole, is a most satisfactory one.

THE ADMINISTRATIVE COUNTY OF LONDON AND DISTRICT ELECTRIC POWER BILL.

(Continued from page 166.)

On Friday last Mr. A. C. MORTON, chairman, Streets Committee, City Corporation, stated that the Corporation objected to the Bill on the score of monopoly. As it was, there were two companies in the City, which was entitled to the benefit of the competition between them.

Sir RALPH LITTLER, K.C., presenting the case for the City generally, held that the purchase clause was quite illusory and impracticable.

The Hon. J. D. FITZGERALD, K.C., said that, having regard to the lateness of the session, he would only deal with the salient features raised in the criticisms against the Bill. Numerous objections had been taken to various clauses as though they represented some departure, but they were just the clauses that had been inserted in other Power Bills. Counsel emphasised the fact that the promoters could only enter the area of an existing authority with the consent of the Board of Trade. The suggestions that large power consumers would benefit at the expense of the small users were quite unjustified, as the same maximum applied to all. The opposition of the Metropolitan Company was due to an attempt to obtain a better bargain than was agreed upon before the Lords' Committee. Counsel then urged strongly the claims of industrial London to a cheap power supply. The present undertakings supplied only 4 per cent. of the horse-power used in London for such purposes. The talk about a monopoly was a mere bogey. Parliament had shown in the past that it was capable of dealing with any attempts of that nature, there was the competition of other forms of power, and Colonel Crompton had stated that consumers could generate for themselves, under certain conditions, at ·65d. per unit. Dealing with the proposed purchase clause, he stated that it was substantially on the lines followed in the Electric Lighting Act of 1888, except that the term was 50 years instead of 42, and he thought that the restrictions the promoters were under regarding capital charges and dividends quite justified this extension. He concluded by appealing to the committee to find the preamble proven on grounds of public expediency.

The committee then adjourned for the interval, and subsequently retired again for a short period, after which the CHAIRMAN stated that, owing to the momentous issues involved, the committee could not arrive at a decision that day. It would be necessary for them to know the precise terms of the purchase clause.

Digitized by Google

The Hon. J. D. FITZGERALD appealed to the committee, on the grounds of urgency and expense, to come to a decision that day, as otherwise it would be almost impossible for the matter to be dealt with in the present session of Parliament. He read the following additional clause in regard to the acquisition of the promoters' undertaking: "Notwithstanding anything in this Act contained the company may, before ascertaining the clear profits of the undertaking available for the payment of dividend, set aside such sums as they think fit to form a sinking fund, which shall remain the property of the company in the event of any purchase of the undertaking, provided that the sums so set aside in any year shall not exceed an amount equal to 1 per cent. per annum on the paid-up capital of the company for the year, and the aggregate of such sums shall not at any time exceed an amount equal to one-third of the paid-up capital of the company for the time being."

The CHAIRMAN intimated that, while the committee appreciated the promoters' difficulties in regard to time, the great interests at stake necessitated further consideration. The committee would, however, proceed with the matter at 11 o'clock on Monday.

On Monday the committee sat from 11 a.m. till 7.30 p.m. in hopes of finishing the clauses, but the new proposals were so numerous that the matter had to be again adjourned. At the opening of the proceedings the CHAIRMAN announced the decision of the committee, which by a majority was that, subject to the consideration and approval of clauses and amendments, it would report to the House that the preamble of the Bill was approved.

The consideration of the clauses in the Bill was then commenced, proposed new clauses being left until afterwards. Many of the objections to the clauses were thrown out. Thus on Clause 3 West Ham asked that words should be inserted which would give protection against the generating station of the promoters becoming a nuisance as regards the emission of smoke.

Mr. FITZGERALD, K.C., pointed out that the clause in the Bill followed exactly the recommendations of Lord Cross's Joint Committee of both Houses to the effect that the liability in common law in the case of persons exercising statutory powers and duties was sufficient. It was simply nonsense to say that under such a clause a smoke nuisance could not be dealt with.

The committee, after hearing evidence, passed the clause unamended.

On Clause 5 further protection for the tramway undertakings of the London County Council and West Ham was asked for, but this was not granted. Clause 18 was altered to prevent the company from dividing premiums on shares as profits. The altered paragraph reads: "All moneys raised under this Act, whether of shares, or debenture stock, or premiums obtained from the issue thereof, shall be applied only to purposes to which capital is properly applicable." The use of Greenwich Tunnel for mains was deleted from Clause 33, and the question of laying mains by agreement with the London County Council in Blackwall Tunnel was deferred for the parties concerned to make terms with each other.

Mr. FREEMAN, K.C., asked the committee to transfer the boroughs of Camberwell, Deptford, Woolwich, and Poplar from the industrial to the non-industrial area. Counsel for Hackney, Shoreditch, and Ilford proposed similar amendments.

The CHAIRMAN said the division of the area could not be altered.

Sir R. LITTLER, K.C., asked that an amendment should be made to prevent the company from carrying mains through the City. He complained that behind the backs of the Corporation an agreement had been come to with one of the companies supplying the City.

Mr. FITZGERALD denied that this was so. The mains must pass through a certain but not a large part of the City.

The committee by a majority decided against the amendment.

Proposals to omit Ilford and West Ham from the area of supply were rejected by a majority. A number of other amendments were debated and rejected. One of these provided that electricity for lighting should be supplied through separate meters, which would be open for inspection by the local authorities, so that it would be possible to know the proportion of energy which was being used for lighting purposes. While the amendment was disallowed, Mr. Fitzgerald agreed to the insertion of a proviso that where any person supplied by the company used a supply for lighting except in accordance with the provisions of the Act, the company should, on becoming aware thereof, discontinue the supply for lighting, and be liable to a penalty of 40s. for each day's default. An amendment was, moreover, accepted giving power to the local authority to inspect works with the view of ascertaining the amount of electricity used for lighting purposes.

Clause 63 was amended so that any 20 consumers could demand a revision of prices every five years. The Board of Trade will then consider the matter.

The question of the powers of the company to purchase complete undertakings was deferred. An amendment was accepted by which the company cannot purchase any undertaking within the city of London without the consent of the Corporation, which consent is not to be unreasonably withheld. After consideration this amended clause was made applicable to all local authorities within the proposed area.

On Clause 74 the London County Council obtained the right to be heard before any Board of Trade enquiry as to delay in the carrying out of the proposed works and consequent withdrawal of powers.

The purchase clause, which sets out the terms on which the company's undertaking might be acquired, after a period of 50 years by some board or authority authorised by Parliament, was altered so that the period should be 42 years.

Several new clauses proposed by the opponents of the Bill were considered and not accepted, and the committee then adjourned.

The new purchase clause as amended reads as follows:

In the event of any public authority or body of trustees (hereinafter called the "purchasing authority") being authorised by Parliament to acquire the undertaking at the expiration of a period of 42 years from the passing of this Act, and of subsequent periods of 10 years thereafter, the following provisions shall apply and have effect—that is to say:

1. Not less than 12 months' notice in writing shall be given to the company by the purchasing authority intimating their intention to acquire the undertaking.

2. Such purchase shall be made upon the terms of the purchasing authority paying to the company in respect of the undertaking the then value thereof as determined in accordance with the provisions of Section 2 of the Electric Lighting Act, 1888.

3. As from the date of purchase the undertaking shall be transferred to and vested in the purchasing authority, and such authority, to the exclusion of the company, shall have and may exercise all the rights, powers, authorities, and privileges of the company, and shall be subject to all the duties, obligations, agreements, and liabilities of the company in like manner as if they were the company, except the debts due by the company at the date of purchase, and the liabilities with respect to the debenture stock and mortgage debt of the company.

4. For the purposes of this section "the undertaking" means all lands, buildings, works, materials, and plant of the company suitable to and used by them for the purposes of their undertaking, but shall not include any insurance fund, reserve fund, or sinking fund authorised by this Act, or cash in hand or at bankers, securities for money, or any debts due to the company.

In consideration of the reduction of the period for purchase from 50 to 42 years, the following section was added to the Bill:

Notwithstanding anything in this Act contained, the company may, before ascertaining the clear profits of the undertaking available for the payment of dividend, set aside such sums as they think fit to form a sinking fund, which shall remain the property of the company in the event of any purchase of the undertaking. Provided that the sum so set aside in any year shall not exceed an amount equal to 1 per cent. per annum on the paid-up capital of the company for the year, and the aggregate of such sum shall not at any time exceed an amount equal to one-third of the paid-up capital of the company for the time being.

On Tuesday last a number of new clauses for the protection of the city of Westminster were discussed and

Digitized by Google

rejected. One of these asked that all mains should be laid on the cut-and-cover system, so that they would afterwards be accessible. The company were also asked to erect street boxes on land purchased for the purpose, but they had no power in the Bill to buy land for the purpose. Another proposal was that all vehicles used by the company in connection with their work should be under the regulation of the Westminster City Council.

The committee, with one dissentient, rejected the clauses.

Some clauses held over from Monday were then considered. It was agreed that "in respect of all electric lines laid down by the company in any street in the administrative county of London, the London County Council shall for the purposes of this section have all the rights, powers, and privileges of the local authority." This was introduced to protect the interests of the London County Council tramways and sewers. An agreement was announced between the company and the London County Council as to the laying of mains through the Blackwall Tunnel. At the same time the company agreed to accept the modified sliding scale suggested by the Council's expert. This now reads: "The dividend which the company is authorised to pay in that year may be increased in the ratio of one-eighth per centum," etc., instead of one-quarter. The clause, after discussion, was agreed to, the effect being that when the average price per unit drops to ½d., the dividend will only be 11 per cent., instead of 15 per cent., but, on the other hand, if the price averages 1d., the dividend will be 4 per cent., whereas before there could be no dividend.

Other special clauses were refused, but Battersea was promised that mains should not be laid in St. John's hill and Lavender-hill if alternative routes were found available.

Sir RALPH LITTLER, on behalf of the City Corporation, asked the committee to insert a clause which read as follows: "The company shall not, either directly or indirectly, oppose the preamble of any Bill which may hereafter be introduced to supply energy in any area within the company's area of supply." This was not accepted, and the same fate met a proposal from Mr. CLODE on behalf of the London County Council. He explained that by the purchasing clause nobody had an absolute right to purchase, and such a right must hereafter be acquired by the parties coming to Parliament and obtaining a right by an Act of Parliament. This proposed clause was to prevent the present company opposing such a proposal if made, and was really to make the purchase clause substantial.

Mr. FITZGERALD said this would be legislating for 40 or 50 years hence. Such a Bill might contain matters most prejudicial to the company, and it was unreasonable to ask for such a clause.

The CHAIRMAN said the committee were unanimous that they could not accept such a clause. He was glad to say their last decision on the Bill was unanimous. They ordered that the Bill be reported to the House.

ELECTRIC WINDING MACHINES.*

BY PROF. PAUL HABETS, OF BRUSSELS.

(Concluded from page 161.)

The motor, M (Fig. 12), is a separately excited continuous-current machine; its rated power is 320 h.p. at 64 r.p.m., and at 500 volts. It will carry an overload of 40 per cent. for half an hour, and of 100 per cent. for five minutes. It will reverse without moving the carbon brushes, and gives no sparking even when the voltage is considerably reduced. The terminals of the haulage motor are electrically connected with the generator, G^1 (Fig. 12), of the Ilgner motor-generator, M^1—G^1, and a maximum current release, which

See also Fig. 11

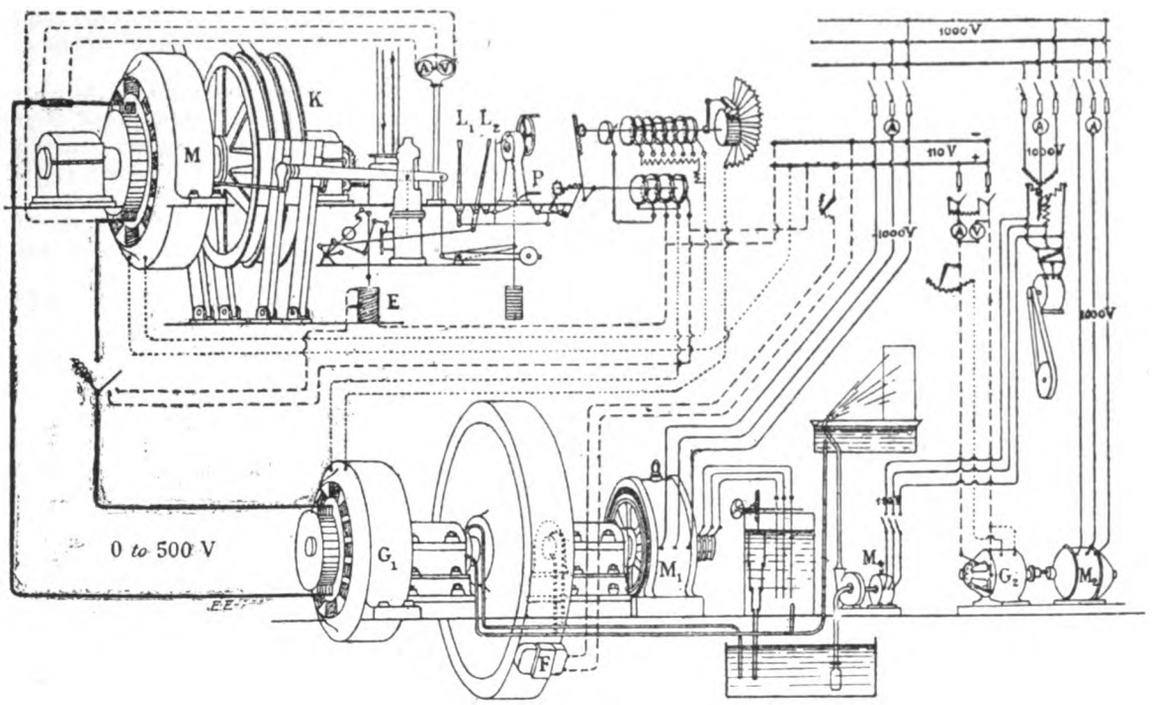

FIG. 12.—Diagram of Installation.

acts when the current reaches 1,500 amperes, is inserted in one of the leads. The output of the continuous-current generator, which is separately excited, is 650 kw. at 500 volts when making 285 r.p.m.; the rise of temperature, measured by the increased resistance, does not exceed 45deg. The carbon brushes have no lead even when the machine is generating the maximum current required by the motor. The machine will also generate the current without sparking at voltages varying between zero and ± 500. These results are due to the large proportions of the generator, whose power is more than double that of the haulage motor. The generator and the haulage motor are of similar design. The cast carcass carries the pole-pieces of laminated iron, which are fixed by bolts in such a manner that they can be removed laterally without dismounting the armature. The field coils are protected by the carcass, and the bobbins are divided into sections for the purpose of ventilation. The armature is a drum, the conductors being tooled and placed in the grooves of the sheet-iron core; the openings between the conductors allow of an effective cooling by circulation of air. The haulage motor, M, and the generator, G^1, are both excited by a small motor-generator, M_2—G_2, which

* Paper read before the Institution of Mechanical Engineers (translated from the French).

Digitized by Google

supplies a continuous current at 110 volts. This motor-generator consists of a 27-h.p. asynchronous motor, M_2—supplied with current from the power station and making 820 r.p.m.—and an 18-kw. continuous-current shunt generator, G_2. The armature of the main generator, G^1, is mounted on the end of the shaft, which also carries, between its two bearings, a flywheel of cast steel, 4m. (13ft. 1½in.) in diameter and weighing 40 tonnes (39·3 tons). The rotor of the asynchronous motor, M^1, which drives the Ilgner group, is mounted on the other end of the shaft; it will exert 250 h.p. at a continuous run af 285 r.p.m. For the purpose of inserting a liquid rheostat in the rotor circuits, on starting the machine, the rotor is provided with slip-rings. An electromagnetic brake, F, when excited, will generate eddy currents in the flywheel rim, and will stop the motor-generator in about a quarter of an hour. Without this contrivance, it would take several hours to bring the machines to a standstill on account of the large amount of energy stored in the flywheel. The bearings of the motor-generator are lubricated by means of rings; the steps are cooled by circulation of water from a vessel at a higher level. The water flows into the grooves of the bearings and into the reservoir of the starting rheostat, and falls into a cistern. A small centrifugal pump, worked by a 2-h.p. asynchronous motor, M_1, takes the water back to the high-level vessel. The pump can lift five litres (1·1 gallon) of water per second through a height of 15m. (49ft. 2½in.), and forces the water as a spray against a cooling screen. The reversing of the haulage motor is brought about by manipulating the lever, L_1, of a controller. According to the position of the lever, the following will take place: (1) simultaneous reversing of the field current of the generator, G^1, and the haulage motor, M; (2) reducing the field current of the haulage motor and interrupting the field circuit of the generator, when the motor is stopped; (3) increasing the field current of the generator progressively, by cutting resistances out and thus causing the voltage of the generator as well as the speed of the motor, M, to increase progressively. While the lever, L_1, is turned back towards the position "stop," the counter E.M.F. generated in the haulage motor (driven by the inertia of the moving masses) will become higher than the E.M.F. generated in G^1. The motor will become a generator and will act as a brake, thereby reducing the period of retardation. The Koepe pulley, K, is provided with two brake rims. The brake, which is worked by compressed air, is only used by the driver for holding the pulley during the standstill of the machine, and is manipulated by means of a lever for admitting the compressed air into the cylinder. It also acts as a safety brake when the three-phase circuit is interrupted. An electromagnet, E, excited by the field current, will then be demagnetised, a counterpoise will be released, and the brake will be brought into action. The brake will also act when the maximum release breaks the circuit, as the field circuit will also be interrupted. When the cage overshoots the landing stage, the indicator, showing the travelling of the cages, will cause the maximum release to break the circuit, and the brake will consequently be brought into action. The brake may also be applied by working the pedal, P, which will release a counterpoise. The retardation is also brought about by the indicator, which causes the lever, L_1, to be moved towards the position "stop" as the cage approaches the pit bank. This automatic movement is often limited, so as to allow the driver to finish the "lift" and to manipulate the machine. The compressed air required for the brake is supplied by a small compressor driven by a 5-h.p. three-phase motor at 120 volts. The different machines and apparatus, as well as the electrical connections, are shown in Figs. 11 and 12.

2. *Description of the Trials and the Results.*—The haulage machine just described has been submitted to a series of trials with the object of giving an account of the performance of the Ilgner system; also of testing the consumption guaranteed by the contractor, and finally of determining the consumption of energy under actual working conditions. The trials were made on Jan. 8, 10, 29, and 30, 1905.

(*a*) *No-Load Trials.*—The difficulty of starting the heavy flywheel, which squeezes the oil out from the bearing surfaces, makes it necessary to keep the Ilgner machine group in permanent motion, as the haulage machine does not stop for very long. The consumption of energy while the Ilgner group is working on no load has an important bearing on the economy of the system, and it was, therefore, decided to determine this consumption. A Siemens wattmeter and an electricity meter were inserted in one of the motor leads, M^1, and readings were taken every five minutes during a period of 35 minutes, the machine making 313 r.p.m. According to the readings of the wattmeter, which had been specially standardised, the consumption was 31·94 kilowatt-hours. The electricity meter showed a consumption of 30·85 kilowatt-hours. The temperature of the oil on the bearings was 30·8deg. C. (87·4deg. F.). By stopping the circulation of the water for 4½ hours the temperature of the oil on the bearings rose to 45·5deg. C. (113·9deg. F.). Under these circumstances, and the shaft making 315·5 r.p.m., the consumption according to the wattmeter and the electricity meter was 30·55 kilowatt-hours and 29·82 kilowatt-hours respectively. According to another trial, repeated on Jan. 29, the consumption was found to be 28 kilowatt-hours at a speed of 314 r.p.m. The temperature of the oil was 35·7deg. C. (96·3deg. F.). The latter consumption corresponds to that guaranteed by the contractor. The efficiency of the motor at this reduced load was 0·6; the windage of the Ilgner group and the friction between the journals and the bearings absorbed, therefore, about 17 kilowatt-hours.

(*b*) *Passive Resistances in the Pits and in the Haulage Motor.*—These resistances were determined by giving the masses a certain velocity and measuring the height through which the useful load was lifted. The energy consumed by the passive resistances would then be equal to the kinetic energy stored in the moving masses minus the work done on the useful load. The suspended loads were:

	Kg.	About
460 + 400 = 860m. (2,820ft.) of rope at 5·6 kg. per metre (3·76lb. per foot)	4,800	(10,600lb.)
2 cages with attachments at 2,100 kg. (4,630lb.)	4,200	(9,260lb.)
8 empty tubs at 250 kg. (551lb.)	2,000	(4,408lb.)
4 loads of coal at 535 kg. (1,180lb.)	2,140	(4,720lb.)
Total	13,140	(28,988lb.)

The diameter of the Koepe pulley (reduced by wear) was 2·88m (9ft. 5⅜in.). The moment of inertia of the suspended loads was $= \frac{13{,}140 \times 1{\cdot}44^2}{g} = 2{,}780$kg.-m.^{2} (65,970 lbs.-feet^2).

The moments of inertia of the rotating masses were:

		Kg.-m.^{2}	Lb.-ft.^{2}
1.	Moment of inertia of the Koepe pulley	630	(14,950)
2.	,, ,, motor armature	250	(5,932)
3.	,, ,, head pulleys	675	(16,018)
		1,555	(36,900)

The moment of inertia of the masses was thus I = 2,780 + 1,555 = 4,335 kg.-m.^{2} (65,970 + 36,900 = 102,870 lbs.-feet^2). The kinetic energy corresponding to a speed of 8m. (26ft. 3in.) per second equals $\frac{I\,\omega^2}{2}$ $\omega = \frac{8}{1{\cdot}44} = 5{\cdot}55$, and, therefore, $\frac{\omega^2}{2} = 15{\cdot}4$ hence the kinetic energy $= \frac{I\,\omega^2}{2}$ = 66,759 kg.-m. (482,900 feet-lbs.) The loads travel through a height of 29m. to 30m. (95ft. to 98ft.) after the current has been cut off from the motor. The work done by the non-balanced load was thus 2,140 × 29 = 61,060 kg.-m. (441,647 feet-lbs.) to 64,200 kg.-m. (464,400 feet-lbs.) The kinetic energy of the masses is between $\frac{66.759}{64,200} = 1{\cdot}04$ and $\frac{66,759}{61,060} = 1{\cdot}095$ times the work done in raising the non-balanced loads—*i.e.*, the useful work. The resistances in the pits and in the machine are, therefore, only 4 to 9½ per cent. of the useful work. We shall see that these figures, which may at first seem rather small, agree with other tests.

(*c*) *Guaranty Trials.*—The object of these trials is to determine whether the consumption in kilowatts per useful horse-power developed by the machine comes within that guaranteed by the contractor. The guaranty had been fixed by assuming a haulage of 30 up and down journeys per

Digitized by Google

hour; each journey included a loading at the bottom landing stage at a depth of 368m. (1,207ft.), and a stoppage on the way at one of the intermediate loading stages, at depths of 342m., 288m., and 185m. (1,122ft, 945ft., and 607ft.). Three series of trials were made on Jan. 10 and repeated on Jan. 30; each trial included 10 up and down journeys made as quickly as possible. Series I. comprised journeys with loadings at 368m. and 342m. (1,207ft. and 1,122ft.); series II. comprised journeys with loadings at 368m. and 288m. (1,207ft. and 945ft.); series III. comprised journeys with loadings at 368m. and 185m. (1,207ft. and 607ft.) At each of these trials the following observations were taken every 10 seconds: (1) Readings of the Siemens wattmeter (the same as used at the no-load trials) which was inserted in the joined circuit of the Ilgner group and the motor-generator, M_2-G_2. These readings were plotted with time as abscissæ, and the integration of the curve gave the total electric energy spent during the test. This energy was also determined by means of the electricity meter by taking readings at the beginning and at the end of the tests. The results obtained by these two instruments differ only 1 to 3 per cent. (2) Readings of a Weston ammeter and voltmeter which were connected to the same circuits. From these data we may plot the curve of apparent alternating watts; and by dividing the watts found by the wattmeter by the apparent watts, we obtain a curve representing the variations of cos of the installation. (3) Readings of the ammeter in the field circuit. The latter was maintained at 110 volts. Recording instruments give an account of the volts and amperes of the continuous current which drives the haulage motor. By multiplying the simultaneous volts and amperes, we obtain the watt curve of continuous current, which represents the power spent at any moment during the haulage; and by integrating the corresponding parts of the curve, we determine the energy spent during the different parts of the journey. The variation of speed of revolution of the Ilgner group was shown by a recording speed indicator. The variation of kinetic energy of the group from the beginning to the end of each trial had to be added (algebraically) to the consumption of the electric energy, found by means of the electricity meter or the Siemens wattmeter, in order to determine the total expenditure of energy.

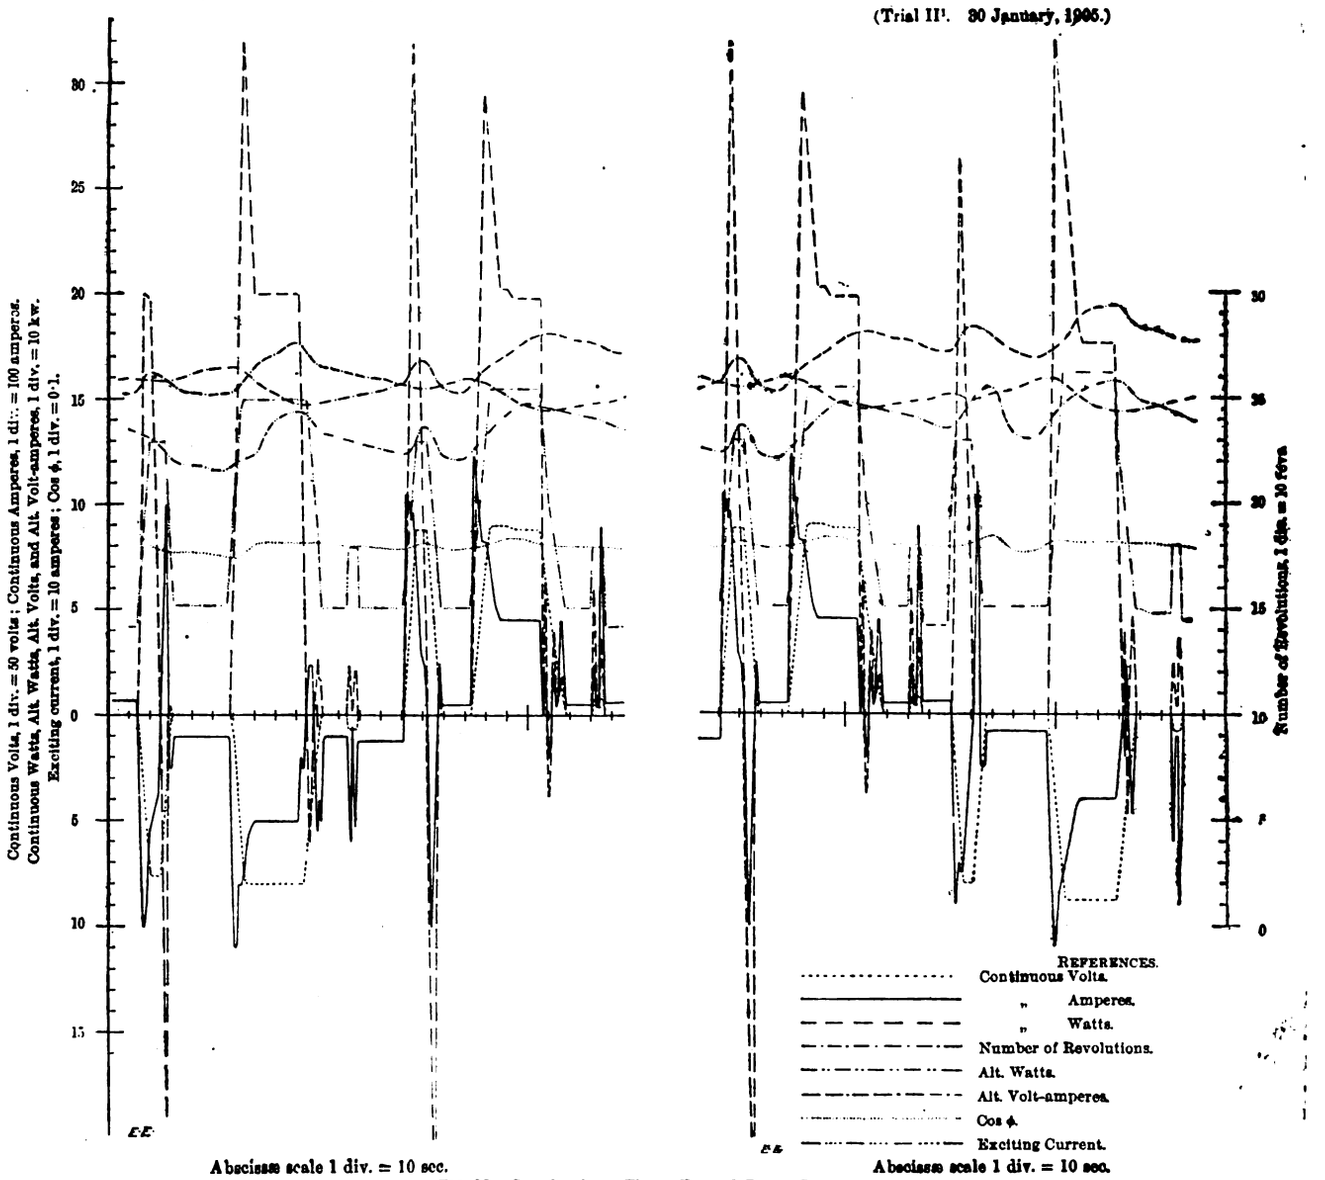

FIG. 13.—Results from Three Up and Down Journeys.

	Kg.-m.²	Lb.-ft.²
The moment of inertia of the rotor of motor, M^1...	65	(1,543)
The moment of inertia of flywheel	1,000	(23,730)
The moment of inertia of the armature of generator, G^1	160	(3,796)
The moment of inertia of shaft	5	(118)
Total.....	I = 1,230	(29,187)

The variation of kinetic energy

$$= \frac{(\omega_1^2 - \omega_2^2)}{2} \times I = \frac{(n_1^2 - n_2^2)\ 2\ \pi^2}{3,600} \times I,$$

where n represents the number of revolutions of the Ilgner group as indicated by the recording speed indicator.

The author does not consider it necessary to publish all the figures and curves obtained by these trials, as their number is very considerable. Fig. 13 represents the results from three up and down journeys of trial II¹ made on Jan. 30. The trials comprised 10 complete journeys from landing stages at depths of 368m. and 288m. (1,207ft. and

Digitized by Google

945ft.). The performance of the Ilgner system is indicated by this diagram. It will be noticed that the power absorbed by the haulage motor (continuous watts) varies considerably—viz, from zero to about 300 kw., then falls to 200 kw. and returns to zero. The power supplied by the power station (alternating watts) varies only between 110 kw. and 160 kw. The results which may be deduced from these trials will be found below, and from these we have determined the efficiency R_1 = ratio of useful power to power supplied to the haulage motor (continuous watts) and efficiency R_2 = ratio of useful work to the sum of the energy spent by the alternating current and the kinetic energy stored in the Ilgner group. The watts consumed per useful horse-power spent in drawing coal is determined by dividing 746 watts by R_2. The consumptions given above are slightly smaller than those guaranteed by the contractor. The consumption at the power station of Espérance is 11 kg. (24¼lb.) of steam per kilowatt-hour; the consumption at the trials would, therefore, be between 17·75 kg. and 20·3 kg. (39·1lb. and 44 75lb.) of steam per useful horse-power hour, which is very small for a winding machine. It is possible to produce a kilowatt-hour by a much smaller consumption of steam; the consumption guaranteed for a steam turbo-alternator working at a pressure of 6·5 kg. (14·3lb.) and superheated 300deg. C. (572deg. F.) is 8·05 kg. (19 73lb.). Adopting this figure, we should require 14 40 kg. to 16·5 kg. (31·74lb. to 36·37lb.) of steam per useful horse-power hour, and we may even go below these figures. The electric winding machine can, therefore, compete with the very best steam winding machines. Mr. Henry, engineer to the Hasard Collieries, has not succeeded in reducing the consumption below 18·94 kg. (41·7lb.) of steam per useful horse-power hour, notwithstanding the best known improvements. It will be noticed that the efficiencies, R_1, are very high. If the mean value of R_1, 0 855 (from the trials on Jan. 30), be divided by the efficiency of the haulage motor, the reciprocal of this quotient will be the factor by which the useful power must be multiplied in order to obtain the power required by the haulage motor to overcome the useful loads and the passive resistances. If the efficiency of the haulage motor (neglecting the field current) be taken as 0·95, then we have $\frac{0·855}{0·95} = 0·90$ and $\frac{1}{0·90} = 1·11$; the passive resistances, therefore, do not exceed 11 per cent., which agrees fairly well with the figure already found above.

Trial.		Number of up and down journeys per hour.	R_1.	R_2	Mean useful work per hour in H.P.	Consumption per useful H.P. in kw.

(*d*) *Consumption of Energy under Working Conditions.*—For the purpose of determining the consumption in kilowatts per useful horse-power, the haulage machine at the pits of St. Nicolas has been submitted to a permanent set of trials, lasting from Jan. 17 to March 1, 1904. The consumption was measured by the electricity meter, inserted as in the guaranty trials. The readings were taken every day at 6 and 8 a.m., and at 3 and 6 p.m. The number of revolutions made by the Ilgner group were read off simultaneously with the readings of the electricity meter, and a record was made of the coal and stones drawn during the different intervals of time. By means of these data the useful work done by the machine may be determined, as well as the mean work per hour. The consumption of electric energy, to which is added or subtracted the kinetic energy of the Ilgner group, admit of determining the consumption in kilowatts per useful horse-power. The large number of results from the trials, which lasted over a period of one month and a half, have been plotted (Fig. 14) by taking as ordinates the consumption in kilowatts per useful horse-power, and as abscissæ the mean useful horse-power given off by the machine. The points lie evidently on an hyperbolic curve. During the night, when the haulage is less, the ordinates are longer, on account of the permanent consumption of the Ilgner group. The ordinates will be shorter as the haulage becomes more active, and

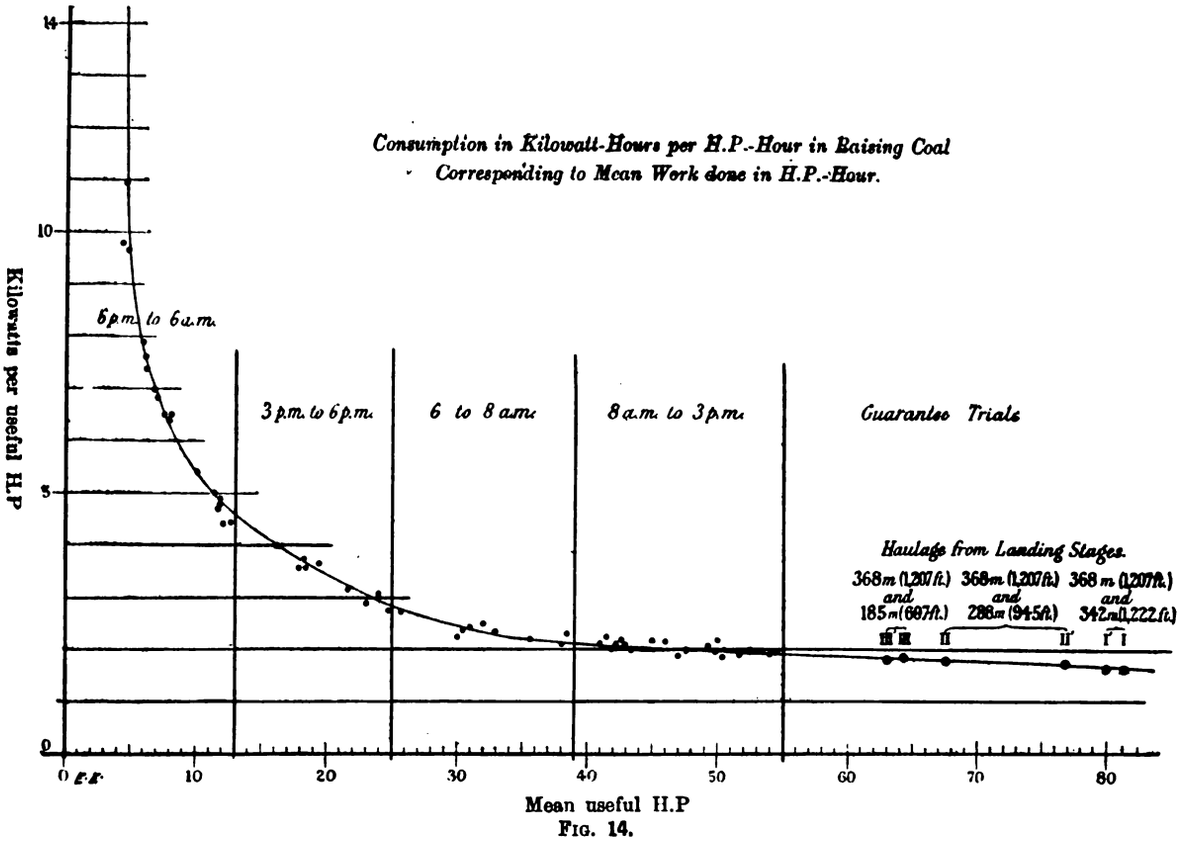

FIG. 14.

Digitized by Google

will be about 2 kw. per horse-power between 8 a.m. and 3 p.m. The results from the guaranty trials have also been plotted; these points lie on the continuation of the curve. It may be remarked that the hyperbolic curve is similar to that representing the consumption of a steam-driven winding machine. The high consumption during the night may be attributed to the Ilgner system, and would, therefore, not take place if the winding machine were driven by an asynchronous motor; but then one would have to take into account the consumption of energy required to keep a dynamo at work at the power station, which should be large enough to generate the maximum power required for starting the winding machinery. At the instance of the machine at pit No. II. Preussen the author has shown that the variation of consumption of a winding machine driven direct by an asynchronous motor follows also an hyperbolic law. The electric winding machine at St. Nicolas has replaced a steam-driven machine, which was put down in 1874. According to trials made on Feb. 17, 1903, the steam-driven machine consumed 53·1 kg. (117lb.) of steam per useful horse-power hour during the period of maximum haulage from 8 a.m. to 3 p.m. By installing the electric machine, a battery of six boilers, working at a pressure of five atmospheres, has been abolished. These boilers were in such a bad state that they would soon have had to be replaced by new ones. Besides being economical in consumption, the electric machine has also caused a reduction in wages, as the stokers who were dismissed from St. Nicolas have not been taken into service at the power station. As the electrically-driven machine is much simpler to manipulate than the steam-driven machine, the drivers (two in number) needed very little instruction before taking over the new machine. The consumption of the accessories is very small. The rope is a flat steel rope. The two ropes which were used at first consisted of six hawsers of four strands each, on a core of hemp; each strand contained seven wires of 2mm. ($\frac{5}{64}$in.) diameter. The ropes were 92mm. ($3\frac{5}{8}$in.) wide and 20mm. ($\frac{51}{64}$in.) thick, weighing about 5·7 kg. per metre (3·8lb. per foot). The wires were of steel with a breaking strength of 140 kg. to 150 kg. (320lb. to 330lb.), and would bear 14 bendings over a mandrel of 5mm. ($\frac{1}{5}$in.) and 30 torsions on a length of 200mm. ($7\frac{4}{5}$in.) before rupture. The total breaking strength of the rope was 77,750 kg. (76·5 tons). The first rope was removed after only three months of service, on account of unnecessary precaution. It was found by a tensile test that the total breaking strength of the weakest part of the rope was still 66,000 kg. (145,504lb.). The second rope lasted $4\frac{1}{2}$ months. It was replaced by a rope consisting of seven hawsers of four strands each, on a core of three wires of 1·2mm. ($\frac{1}{32}$in.) diameter, each strand containing seven wires of 1·8mm. ($\frac{5}{64}$in.) diameter. The rope, being 110mm. ($4\frac{21}{64}$in.) wide and 18mm. ($\frac{45}{64}$in.) thick, weighs about 5·75 kg. per metre (3·8lb. per foot). The wires are of steel, with a breaking strength of 130 kg. to 135 kg. (286·6lb. to 297·6lb.); the 1·8mm. ($\frac{5}{64}$in.) wire would bear 18 bendings over a mandrel of 5mm. ($\frac{3}{64}$in.) and 30 torsions on a length of 200mm. ($7\frac{7}{8}$in.). The 1·2mm. ($\frac{1}{32}$in.) wire would bear 36 bendings and 30 torsions on a length of 150mm. ($5\frac{29}{32}$in. or 5·9in.). The total breaking strength of the rope is 77,000 kg. (75 8 tons). On account of the small diameter of the Koepe pulley, it was desirable to give the new ropes more flexibility by making them thinner and of finer and more ductile wire. It is interesting to compare the expenses, with regard to ropes, of the Koepe machine with those of the old steam-driven machine with bobbins and flat aloes ropes. The latter ropes weighed about 4,600 kg. (10,141lb.), and cost during later years from 1·65fr. to 2fr. per kilogramme (7d. to 8·71d. per pound). Let us adopt the lowest figure: a rope will then cost 7,600fr. (£304), and two ropes will, therefore, be 15,200fr. (£608). These ropes last about 26·32 months—say 30 months on an average. The rope expenses per month would, therefore, be 500fr. (£20). The ropes which were rejected cost 2,250fr. (£90), which for a period of $4\frac{1}{2}$ months is 500fr. (£20) per month, the same as we found for the aloes ropes. One may, however, expect to find the steel ropes more economical, as their construction is more suitable for the purpose, and may, therefore, last more than $4\frac{1}{2}$ months. A rejected haulage rope may be used as counter rope.

It may safely be concluded from these trials that the electric haulage machine, even if it is not more economical than the best steam-driven machine, is certainly not more expensive. The greater facility and safety with which it can be manipulated, the smoothness with which it works, and its much greater flexibility, will often make it preferable to the steam-driven machine, even in the case where transmission of energy is not required. There can be no hesitation in the choice between the two systems when the power has to be transmitted from a distance, or, as in the case of the pits of St. Nicolas, where the production of energy can be centralised at one power station.

TRADE NOTICES AND NOVELTIES.

A Novel Sample Cabinet.

The accompanying illustration represents a novel sample cabinet which has been prepared by the Simplex Steel Conduit Company, Limited, Westinghouse-building, W.C., with the idea of supplying on loan to station engineers, architects, lecturers, etc., a set of samples for inspection, as they are far more convenient loose than mounted on a board. The cabinet contains four trays, so that the samples can be classified into main groups, and as each tray is subdivided, the groups can be further arranged in sections. If the trays containing the

Simplex Sample Cabinet.

samples are placed out on a table with the tools from the bottom of the box, an excellent idea of the completeness of the Simplex system of conduit wiring can be obtained. A detailed description of the cabinet and its contents is given in a leaflet recently issued by the company.

A Useful Draught Gauge.

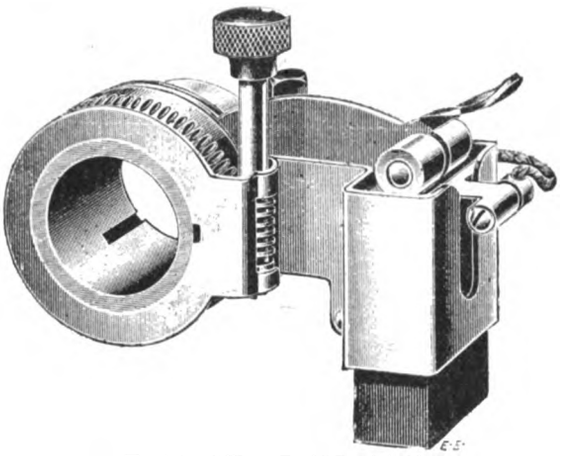
The "Phœnix" indicating and recording draught gauge is a useful device which not only shows on a dial, but also automatically registers on a chart, the exact draught in a boiler or other furnace, thus enabling the stoker to adjust the dampers in order to obtain the best results possible, and at the same time affording the engineer a reliable means to check the work of his men. Details are contained in a new pamphlet just issued by Messrs. Sanders, Rehders, and Co., 108, Fenchurch-street, London, E.C. Two charts taken at an electricity works, before and after installation of the apparatus respectively, are included to illustrate its usefulness. These charts lead one to the conclusion that a considerable saving of fuel may be effected with the aid of the instrument.

A New Brush-Holder.

Messrs. Veritys Limited, Deansgate, Manchester, have sent us particulars of the "Aston" worm-feed brush-holder just introduced by them. This holder, which we illustrate herewith, is of the "box" type, though the principle of "worm-feed" can equally well be applied to the "finger" type of brushes. The former type, however, is coming more and more

Digitized by Google

into favour with engineers, we are told, owing to the fact that vibration is not so readily transmitted from armature to brush gear by this type as is the case with the more rigid "finger" type. "Box" type holders fail where the attempt is made to obtain a tight contact between carbon and box. In the Aston brush-holders the carbon is a moderately loose fit in the box, and ample contact is provided by a flexible copper connection between carbon and holder. The carbon is fed down without friction by the pressure of two small rollers, which are connected by means of a lever to the "worm-feed" adjustment.

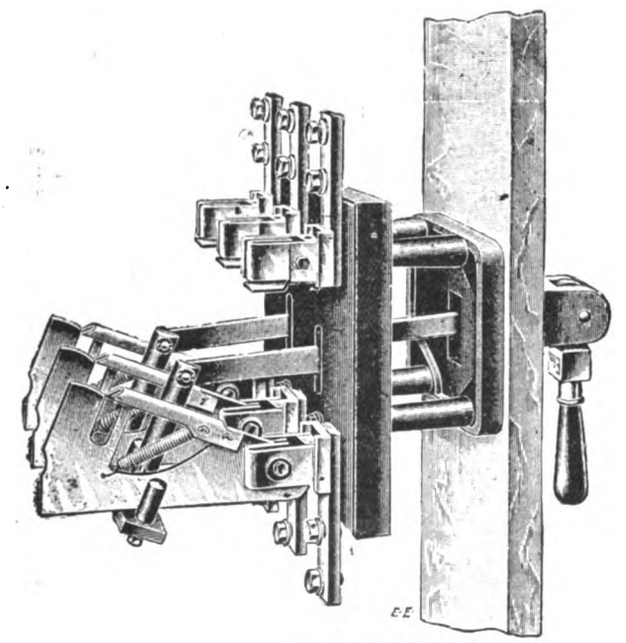


The Aston "Worm-Feed" Brush-holder.

By turning the insulated knob of a small screw, the pressure on the carbon can be regulated to the finest limit. One end of the spiral spring is connected to the worm-wheel, and the other end to the lever, and as the worm-wheel is turned by the thumb-screw, greater or less pressure is put on the carbon. The tube of the holder is split through half its length, and a split ring provided with a steel key is used for tightening the holder upon the brush pillar. The lever is extended beyond the pressure rollers to provide a ready means of raising to try the tension or remove the carbon. A small slot is provided in the front of the carbon-box, and as the carbon is fed forward, the lever finally comes to rest at the bottom of this slot. The possibility of the lever touching the commutator is thus avoided. The thumb-screw is fitted with an insulated knob, so that extra tension can be applied if required while running without fear of shock.

Low-Tension Switchgear.

The Union Electric Company, Limited, 151, Queen Victoria-street, E.C., are issuing a new list of their low-tension switchgear for capacities of from 20 to 6,000 amperes, and voltages up



Union B pattern L.T. Treble Pole Switch.

to 550. Two leading types of switches are dealt with in this list. Pattern B is of small ampere capacity, and made one, two, or three pole. Its leading features are as follows: A replaceable spark-carrying contact with exceedingly rapid break on each pole, which keeps the main contacts entirely free from all sparks; the replaceable finger is held in by split pins, the flat contact by an accessible bolt; arrangement for connections at back or front of switchboard; change-over arrangement with off position, both for front and back of board working; large contact surfaces, the 550-volt types having the same contact area although lesser ampere rating than the 250-volt types. Pattern C is made for larger currents up to 6,000 amperes. It is provided with magnetic blow-outs on all poles, replaceable spark-carrying rollers, and laminated brush contacts. Both types are arranged for mounting behind the switchboard with the operating handle in front. The accompanying illustration shows a treble-pole switch of the first-mentioned pattern. For use in connection with these switches, special open fusible cut-outs and enclosed handle plug carriers are also included in the list.

Catalogues, etc., Received.

WALL TELEPHONE.—The General Electric Company, Limited, Queen Victoria-street, E.C., are advertising their K 25 battery wall telephone by means of a little novelty card, which is an exact facsimile of the instrument. We understand this telephone has been remodelled in order to bring it up to the very highest possible state of efficiency and simplicity, the inside connections being particularly simple. It has the additional advantage of an extremely low price for such a well-finished and efficient article.

PORTABLE DRILLS AND ELECTRICAL ACCESSORIES.—From the Electrical Trades Supply, Limited, Great Charles-street, Birmingham, we have a well-illustrated catalogue of their portable electric drilling machines, also a list of E.T.S. damp and dust-proof electrical fittings for collieries, ironworks, factories, mills, ships, etc.; a list of electrical porcelain ware, including ceiling roses, cut-outs, wall plugs, lamp-holders, brackets, watertight fittings, etc.; and an abridged list of cord pendants, ceiling fittings, brackets, electroliers, and standards.

LEIGH ELECTRICITY ACCOUNTS

We give below an abstract of the revenue account for the year ended March 31, 1905, just issued by the Leigh Corporation Tramways and Electricity Committee.

Dr. *Expenditure.*	£	s.	d.
To generation of electricity	1,461	15	1
Repairs and maintenance of plant	598	11	3
Distribution of electricity	333	19	4
Rents, rates, and taxes	182	19	6
Management expenses, salaries, etc.	357	1	5
Special charges, insurance, etc.	284	4	7

APPOINTMENTS VACANT.

Chief Instructor in Mathematics, Northampton Institute, Clerkenwell. Salary, £150 per session. Applications by 30th inst. See advertisement in last issue.

Premium Pupil, Kilmalcolm Electric Lighting Co. See advertisement in last issue.

Assistant Engineer about 25 years of age, with good knowledge of mechanical engineering. Applications to G M 532, Messrs. Deacon's, Leadenhall-street, London, E.C.

Practical Engineer to supervise the equipment of a complete electrical tramway in India. Applications to Box No. K 10, *Electrical Engineer* Office. See advertisement in last issue.

Mechanical and Electrical Engineer. Salary, 30s. per week. Applications to R. N., *Electrical Engineer* Office. See advertisement in last issue.

Electrician, Monmouthshire Asylum, Abergavenny. Salary, £2 per week. Applications to the Medical Superintendent by 12th inst.

LEGAL INTELLIGENCE.

TRAM COLLISION.

Before Mr. Justice Grantham and a special jury at the West Riding Assizes, Leeds, last week, an action was heard in which Dr. Henry White, of Bradford, claimed £17,200 damages against the Bradford Corporation for personal injuries sustained on Easter Monday. One part of the doctor's claim was £16,000 for loss of practice, past and future. The plaintiff's case was that he was being driven in a phaeton from his residence in St. Jude's-place into Manningham-lane, and on reaching the corner he saw a tramcar coming along Manningham-lane 60 or 70 yards away. Believing there was sufficient time, he attempted to drive across the street to get to his right side. The phaeton had not cleared the car lines, however, when the car dashed into it, and both the plaintiff and his coachman were thrown out. The doctor had been told by his medical advisers that he was quite unfit to do his work. He had been in bed some weeks, and would be unable to follow his practice for a considerable time. The plaintiff contended that the car was being driven at a speed of over 20 miles an hour.

The defence was that when the phaeton drove out of St. Jude's-place at a smart trot the car was only 16 yards away. The driver rang his bell and applied the brakes, and but for the driver of the phaeton hesitating on the rails no accident would have occurred.

The jury awarded the plaintiff £1,500.

COMPANIES' MEETINGS AND REPORTS.

GASLIGHT AND COKE.

At the half-yearly ordinary general meeting of the Gaslight and Coke Co. last week, Mr. HOWARD C. WARD (deputy-governor), who presided, stated that there never was a time when competition was so keen and prices for electric current so low, especially those charged by borough councils who had their own electric undertakings, and who had the rates to fall back upon if they lost money. There had been a considerable saving in several directions. The Corporation of the city of London had decided to experimentally light Queen Victoria-street, Lower Thames-street, and Fleet-street with gas. That was extremely satisfactory, inasmuch as it would not only tend to increase the Company's gas sales, but it also showed that the most important corporation in the world realised that gas was a better and a cheaper light for the streets than electricity. Another matter for congratulation was the fact that they had secured the lighting of the new Victoria Station in competition with electric light at an extremely low figure.

As compared with the corresponding half-year of 1904 there was a considerable falling off. After paying a dividend of £4·8 per cent. there was a deficit of £30,000 in place of the surplus of £98,000 12 months ago.

LONDON ROAD-CAR.

At the forty-fifth half-yearly meeting of this Company, the CHAIRMAN stated that the number of passengers carried was 37,377,896, being an increase of 411,343 over the number carried in the corresponding period of 1904. The weekly average traffic receipts per car were £17. 3s. 7¼d., against £16. 18s. 2d., being an increase of 5s. 5d. per car per week. Of the total number of passengers, nearly one million were carried by motor omnibuses. Although the number of motors was relatively small, their greater earning power had had a considerable effect in increasing the average receipts of the cars, but it was only fair to say that the average receipts of the horse cars were slightly better than in the corresponding period. The experience gained enabled the Board to gauge the situation with tolerable accuracy. Their minds were made up regarding the type of motor which would not be adopted by them, as well as the type which would suit. Generally, the outlook was not unsatisfactory. The balance available for division was £21,903, of which it was proposed to transfer £2,000 to the general reserve, raising it to £60,000. It was also proposed to pay a dividend of 4s. per share on the fully-paid shares, carrying forward £6,613.

NERNST ELECTRIC LIGHT.

An extraordinary general meeting of this Company will be held on 14th inst, when the resolutions passed at the meeting on July 24 will be submitted for confirmation. These resolutions sanctioned the provisional agreement under which it is proposed that the Company shall sell to the Allgemeine Elektricitäts-Gesellschaft all the patent rights possessed by it for manufacturing and selling Nernst lamps elsewhere than in Europe and the United States of America and Canada, and including the Company's rights to the royalties payable by the Allgemeine Elektricitäts-Gesellschaft on deliveries of patented Nernst lamps for Great Britain, for £24,000, to be paid in cash.

ANGLO-AMERICAN TELEGRAPH.

The half-yearly meeting of this Company was held on Tuesday, Mr. F. A. Bevan presiding. Particulars of the report appeared in our last week's issue.

The CHAIRMAN stated that the new half-year had commenced with increased traffic, and they looked forward to a good half-year, in spite of the fact that the Newfoundland authorities had taken it into their heads to impose a tax on them, which might cause a loss of £1,000 a year. They were also threatened with competition in Newfoundland.

The report was approved.

Digitized by Google

SOUTH WALES ELECTRICAL POWER.

An extraordinary general meeting of this Company was held on Saturday at Cardiff, Mr. R. Forrest, J.P., presiding. It was resolved to create £100,000 additional debenture stock of the Company, bearing interest at the rate of 5 per cent. per annum, being the fourth and fifth instalments of £50,000 each, part of the £250,000 which the Company is empowered to borrow under its Act.

NORTH METROPOLITAN TRAMWAYS.

The report for the half-year ended June 30 last states that the gross receipts for the period have amounted to £307,419, and expenditure to £295,524. The number of cars running shows a decrease of 4·25; there was a decline of 44,093 in the miles run, and of £2,506 in traffic receipts. The sum of £11,794 has been charged against revenue for maintenance of the permanent way. For some time past negotiations have been pending with the London County Council for the surrender of the lease of their northern tramways, which was granted by the Council to the Company in October, 1897, and which would not have expired in the ordinary course until June, 1910, and also for the purchase of the properties, cars, horses, etc., which belong to and are employed by the Company in working these tramways. These negotiations have now resulted in an offer by the Council which the directors have decided to recommend the shareholders to accept, and the terms of which have been embodied in an agreement which will be submitted to the shareholders for confirmation at the general meeting to be held on the 16th inst. This agreement, which is to take effect as from April 1 next, will, if ratified, also put an end to various matters in dispute between the Council and the Company.

NEW COMPANIES REGISTERED.

City of Ely Electric Light and Power Co., Limited.—Capital, £5,000. Object: to adopt an agreement with H. Foote, L. Milne, and E. J. Owen, providing for the transfer to the company of the undertaking and powers granted to them by the Ely Electric Lighting Order, 1904, etc.

Newquay Electric Light and Power Co., Limited.—Capital, £15,000. Object: to carry on at Newquay, and elsewhere in Cornwall, the business of an electric light and power supply company in all its branches, and to adopt an agreement with H. Foote, L. Milne, and E. J. Owen for the acquisition of the undertaking and powers granted to them by the Newquay Electric Lighting Order, 1904, etc.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Warrington.—Tenders are required for cables. Tenders by Aug. 11.

Sophia.—The District Finance Commission require tenders for telegraph material by Aug. 25.

Florianopolis (Brazil).—The Municipality require tenders for the lighting of the town by Oct. 2.

Finchley.—The Urban District Council invite tenders for storage batteries and booster. Tenders by Aug. 15.

Turn-Severin (Roumania).—The Mayor invites tenders for the electric lighting of the town. Tenders by Sept. 10.

Olympia 1905 Exhibition.—The Executive Committee invite tenders for the loan or hire of 300-kw. direct-coupled steam set.

Paris.—The Post and Telegraph Department require tenders for rubber-insulated copper wire. Tenders to above, 103, Rue de Grenelle, by Aug. 24.

Madrid.—The Public Works Department require tenders for the construction and working of an electric tramway in Zaragoza. Tenders by Sept. 12.

Madrid.—The Public Works Department require tenders for the construction and working of an electric tramway in Malago (Malaga). Tenders by Aug. 19.

Madrid.—The Public Works Department require tenders for the construction and working of two electric tramways in Barcelona. Tenders by Aug. 18.

Acton.—The Urban District Council invite tenders from manufacturers for the supply of arc lamp carbons and house fuse-boxes for a period of 12 months. Tenders by Aug. 21. See advertisement in last issue.

Larne (Ireland).—Tenders are invited for lighting the public streets and roads of the urban district of Larne by means of coal gas or electricity for three years from Aug. 1, 1906. Tenders by 10 a.m. on Sept. 2.

Alicante (Spain).—The Harbour Board (Junta des Obras del Puerto) require tenders for two electric cranes, capable of lifting 10,000 ko. and 1,500 ko. respectively. Tenders by Sept. 15. Estimate, 107,010·10 pesetas.

Swansea.—The Corporation invite tenders for supply, delivery, and erection of one intercommunication switchboard section for central exchange, and apparatus for sub-exchanges at Morriston and Mumbles. Tenders by Aug. 11.

Erdington.—Tenders are required for the construction of Section No. 1 of the Erdington tramways, comprising the laying of the permanent way, including copper bonding, wood block paving, and other works incidental to the laying of about 2½ miles of double-track tramway, for the Tramway Committee. Tenders to the joint engineers, Mr. Robert Green (of Messrs. Pritchard, Green, and Co.), of 37, Waterloo-street, Birmingham, and Mr. Herbert H. Humphries, engineer to the Council, Public Hall, Erdington.

Chelmsford.—The Town Council invite tenders for lighting the public streets and public clock within the borough with electricity, gas or other illuminating power for three or five years from March 25, 1906. Tenders by Sept. 8.

Dublin.—The Lighting Committee of the Corporation invite tenders for certain alterations and additions to the coal storing and conveying plant at their Pigeon House generating station. Tenders by Aug. 15. See advertisement in last issue.

Paris.—The Waterworks Department of the Municipality require tenders for supply and erection of motors, pumps, and generators for the proposed waterworks at Chantilly. For particulars apply to above authority. Tenders by Oct. 12.

Stalybridge.—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

Merthyr Tydfil.—Tenders are invited by the Urban District Council for the erection of refuse destructor plant capable of effectually burning 120 tons of refuse per day, together with all buildings and contingent works connected therewith. Tenders by Sept. 1.

Fulham.—The Council invite offers for a 300 kw. horizontal compound condensing slow-speed set with condenser complete, consisting of Musgrave engine fitted to a General Electric Co.'s alternator, speed 95 r.p.m. Offers to the Town Clerk by noon on Aug. 16.

Municipal Board of Mussoorie (India).—The Municipal Board invite tenders for the supply, delivery, and erection at sites, in complete working order, of the following plant: (*a*) steel power pipes; (*b*) water-motors; (*c*) alternators with exciters; (*d*) switchboards with instruments and apparatus; (*e*) transformers; (*f*) induction motors; (*g*) pumps; (*h*) workshop machines. Also for the supply and delivery of the following: (*a*) bare copper wire for overhead mains; (*b*) insulators and lightning arresters; (*c*) arc and incandescent lamps; (*d*) telephone equipment; (*e*) workshop tools; (*f*) general stores. Specifications, form of tender, and general conditions can be obtained on application to Mr. C. H. Shanan, municipal electrical engineer, Municipal Office, Mussoorie, India (telegraphic address, Shanan, Mussoorie), on payment of a deposit of Rs.75 (£5), which amount will be returned on receipt of a bona fide tender. Tenders by Oct. 23. See advertisement in previous issue.

RESULTS OF TENDERS.

Colchester.—The Town Council have accepted the tender of W. T. Henley's Telegraph Works Co. for cables at £490. 0s 2d.

Hammersmith.—The tender of Messrs. Foster, at £1,607, has been accepted for the erection of additions to the Borough Council's electric lighting works.

Scunthorpe.—The Urban District Council have awarded the order for storage battery of 122 standard lighting type cells to the Hart Accumulator Co.

Beckenham.—The Urban District Council have accepted the following tenders: Babcock and Wilcox, boilers, £1,171 without brickwork, and £1,946 with brickwork; General Electric Co., alternators, with a Belliss engine, £1,604.

Brighton.—The Town Council have accepted the tender of the Chloride Electrical Storage Co., Clifton Junction, near Manchester, at £3,600, for the supply, erection, and maintenance of a 260-cell storage battery having a capacity of 1,000 ampere-hours at the Southwick power station.

Hampstead.—Eight tenders for the supply of coal and coke to the various depots of the Council—including the electric lighting depot—for one year have been referred to the Works Committee with power to act. The tender of Mr. A. Mercer, of Boundary-road, for relaquering the electric light fittings in the town hall for £13 has been accepted.

Wishaw.—The Town Council have accepted the following offers for the carrying out of the electric lighting scheme, which is expected to be introduced in the beginning of October: Callender's Cable Co., London, underground mains, £5,437. 5s. 3d.; J. M'Ewan. Wishaw, £677. 18s. 4d., excavating and reinstating; Oliver and Co., Woolwich, £539. 10s. 6d., new flame lamps (45 in number).

Metropolitan Asylums Board.—The Board have accepted the following tenders: Messrs. James and Browne, 395, Oxford-street, W., to supply a chassis for £465, and the Electromobile Co., to supply an electrically-propelled ambulance on hire at three months for £10. Group III.—Cars driven by electricity: Electromobile Co., 7, Curzon-street, Mayfair, W., 8 h.p., £460, hire £10 per month; Carl Oppermann Electric Carriage Co., 7, Underhill-street, Camden Town, N.W., £425, hire £20 per month. The purchase price includes the amount to be paid for hire for three months unless otherwise stated.

Bath.—The Corporation have received the following tenders for storage battery for the electricity department:

Tudor Accumulator Co.	£2,483	5	0
Chloride Electric Storage Co.	2 190	17	10
Pritchetts and Gold	2,947	0	0
Premier Accumulator Co.	3 125	11	0

BUSINESS NOTES.

TRACTION.

Nottingham.—A fatality occurred on the Barford line owing to the failure of the lifeguard to act.

Birkenhead.—The experiment of 3d. return tickets to Liverpool is stated to have proved disappointing.

Rotherham.—At the meeting of the Town Council the chairman of the Tramways Committee stated that ½d. fares did not pay.

Kirkcaldy.—The District Committee have decided to take no action in regard to the proposal of the promoters of the Wemyss tramways to lay the rails of lines Nos. 2 and 6 on a raised track.

Rochdale.—The Corporation have rejected the Tramways Committee's proposal for 1½d. workmen's fares on the Littleborough section, holding that it would be politic to charge 1d. only.

Goods Traffic.—At a meeting of tramway managers held at Manchester, under the presidency of Mr. J. M. McElroy, the general opinion was that something should be done to develop goods traffic.

Removal.—The engineer's office of the Metropolitan District Railway has been transferred from Lillie Bridge Works, S.W., to the St. James's Park Station, to which address all future communications should be directed.

St. Petersburg.—It is reported that invitations for tenders for the construction of the St. Petersburg electric tramway system have only been sent to German, French, and Belgian firms, and not to British or American houses.

Charing Cross, Euston, and Hampstead Railway.—The half-yearly report states that the capital expenditure to date is £3,372,694, of which £741,158 was incurred in the past six months. During the current half-year the expenditure is estimated at £750,000.

Limerick.—It was expected that a scheme on the part of a private company for constructing a tramway would be considered by the Corporation last night. It is reported that the promoters intend the system to be for goods traffic only, in which case they are likely to meet with considerable opposition.

Derby.—At the meeting of the Town Council on the 2nd inst. great satisfaction was expressed with the way the contractors (Messrs. Wm. Griffiths and Co.) had progressed with their work. They had gained marks of approval and approbation on all hands, and the Tramways Committee did not think the town had ever had a better lot of men working in the place.

North-East London Railway Bill.—After hearing evidence on the lines of that given before the Commons Committee, the Select Committee of the House of Lords presided over by Lord Ludlow approved of this measure for a tube from the City to Waltham Abbey. Owing to the obstructive tactics of the Irish Nationalists the Bill has had to stand over this session.

Yarmouth.—At the meeting of the Town Council on Tuesday it was reported that the receipts for the past month had been £1,400. 12s. 9d. on the Yarmouth section, an increase of £18. 16s. 11d., and on the newly-electrified Gorleston section £1,070. 2s. 3d., a total of £2,470. 15s. The number of passengers carried during the month on the Gorleston section was 123,336.

Devonport.—The Tramways Committee's recommendation that the company's offer to pay the Corporation a fixed sum to be released from the obligation to erect shelters has been approved. The Corporation will erect several shelters themselves. Experiments are to be made on the Morrie-square route, and if the results justify such a course the company will permanently restore the service on this line.

London County Council.—A short extension of the County Council's tramways system from Blackfriars, Waterloo, and Westminster Bridges has been opened for traffic, and the cars, instead of stopping in Tooting High-street, proceed to Tooting Broadway. This line is shortly to be further extended in two directions, one branch going to the county boundary at Merton, and another to Tooting Junction railway station.

Bath.—Colonel von Donop, representing the Board of Trade, last week visited Bath for the purpose of inspecting the new extension of the electric tramways system. The new route commences from the existing line at the end of Newbridge-road, Lower Weston, and terminates at the Globe Inn, Newton St. Loe. The work, which was commenced on June 9, has been carried out expeditiously. The inspector expressed himself as satisfied with the work.

Aberdeen.—At Monday's meeting of the Corporation the annual tramway accounts were submitted. The gross revenue amounted to £70,430. and there was a net surplus of £12,288, which has been applied to renewals and depreciation. Details of the year's working have already appeared in our columns. The accounts were unanimously approved. It has been decided that the fares for the ensuing year shall remain practically as at present. A proposal to extend the system of ½d. fares was negatived.

Seaham and District Light Railway.—At the inquiry by the Light Railway Commissioners as to the expediency of granting an application for a provisional order to lay tramways from Ryhope to Seaham Harbour, Seaham Colliery, Murton Colliery, and South Hetton, to which we referred last week, Mr. D. Balfour, jun., M.I.C.E., of Messrs. D. Balfour and Son, consulting engineers, Newcastle-on-Tyne, gave detailed evidence as to the route, gradients, lengths, and cost of the line. The chairman intimated the Commissioners' assent to the proposal.

Bury.—The following resolution was adopted at last week's meeting of the Town Council: "To pass a resolution in pursuance of the recom-

Digitized by Google

mendation of the General Purposes Committee approved by the Council, that the resolution passed at a meeting of the Council held on July 6, 1905, altering the resolution of the Tramways Committee on the 9th ult., with reference to obtaining further cars, be rescinded." It was intimated by the chairman of the Tramways Committee that the agreement with Heywood had virtually been concluded, subject to the approval of the respective Corporations.

Tipton.—As the result of negotiations which have been in progress for over 12 months, it is stated that there is now a prospect of an early solution of the tramway difficulty at Tipton, the British Electric Traction Co. having entered into an agreement with the District Council to commence within two months the electrification of the line from Dudley to Princes End, and from Ocker Hill to Wednesbury. Owing to the effect of mining subsidences, the question of the electrification of the intermediate section between Princes End and Ocker Hill is to remain in abeyance.

Ramsgate.—On the morning of the 3rd inst. a remarkable accident occurred on the loop line connecting Ramsgate and Broadstairs. As one of the cars was proceeding along Madeira-road, East Cliff, which is steep and winding, it left the rails, and, dashing into the iron fence and coping which skirted the footway, it was precipitated into space. It appears to have turned a somersault and alighted upon some vacant land 32ft. below. The four passengers and the conductor had remarkable escapes. The driver seems to have been shot out of the vehicle before it fell over, and sustained rather severe injuries. The Board of Trade have intimated that they will hold an inquiry.

Fareham.—The question as to the extension of the tramway line in West-street, over which there has been some discussion between the Gosport and Fareham Tramway Co. and the London and South-Western Railway, has been satisfactorily terminated. The line at present stops at a point about 200 yards from the railway station, and an effort was made by the company and the Urban District Council to obtain a concession from the railway company to run as far as the station. To this the latter demurred, but a letter has recently been received from the railway company granting permission to construct the line to a point within 30ft. of the company's pavement.

Plymouth.—The new section of the Corporation tramways, which extends from Pennycomequick to Old Town-street, *via* Cobourg-street has been inspected by Colonel Druitt, representing the Board of Trade. In the trial run, Mr. Raworth, jun., acted as driver, and in the car were Mr. R. R. Monk (chairman of the Tramcar Committee), Messrs. C. R. Everson, tramway manager, J. Paton, borough surveyor, and Okell, electrical engineer. The car travelled easily, and the inspector expressed satisfaction with the type of car and the trial, but stipulated that a Sprague brake should be fitted to each of the cars for service on this line as a precaution against running backwards down the hill at Pennycomequick. The cars are fitted with Raworth's regenerative control.

Morley.—The Town Council have adopted the following resolution: "That the town clerk write to the British Electric Traction Co. stating that the Corporation are very anxious to have the Morley tramways completed with as little delay as possible, and ask if they will give an undertaking that the railways will be completed within the period if the Council agree to the further extension, and that in the event of an unsatisfactory reply being received from the company, the town clerk be instructed to submit the facts to the Board of Trade." On the one hand, the Corporation is asked by the company to consent to this extension, and, on the other, it is being urged by the democratic section of the community to undertake the construction and extension of the tramways itself.

Tramway Extension in Yorks.—The Tramways Orders Confirmation (No. 1) Bill came on Monday before the Committee on Unopposed Measures at Westminster, the Deputy-Chairman of Committees (Mr. Laurence Hardy) presiding. The Bill confirms orders made provisionally by the Board of Trade empowering the Corporations of Bradford, Leeds, Keighley, and Pudsey to construct tramways. Mr. Bonnor Maurice explained that there was a contest in the House of Lords because the railway companies did not consider that they were sufficiently protected. The clauses objected to had been struck out of the Bill, and new ones inserted. These had been agreed to by all the parties interested, as well as by the Board of Trade. The Bill passed through committee, and was sent for third reading in the Commons.

Glasgow.—At a meeting of the inhabitants of Duntocher the following resolution was carried unanimously: "That this public meeting unanimously resolves to again approach Glasgow Corporation to request an extension of the tramways from Kilbowie to Duntocher, a distance of barely two miles. They submit that as there is a population of over 3,000 people in Duntocher and Hardgate, and a very considerable daily traffic between Duntocher and Clydebank (in which place nearly all the inhabitants of Duntocher are employed), that as the district around the two villages is peculiarly healthy and picturesque, and admirably suited to building purposes, and as a golf course with a large membership has recently been opened at Hardgate, the desired extension would be a great benefit to the locality, would develop the district, and could hardly fail to be remunerative to the Corporation."

Motor 'Buses.—The deputation appointed by Glasgow Corporation to visit the recent Electric Tramway and Railway Exhibition report that very distinct evidence has been given of the development of the motor 'bus in opposition to tramway traction, but they do not view with alarm any opposition from this source in Glasgow, as the expense of renewing the rubber tyres is admittedly very heavy, the cost being 2d. per mile run even on smooth pavement. They could not, therefore, be run on a paying basis on the square setts of the city streets, while the rough ride on the irregular streets would compare unfavourably with the smooth running of the cars. The deputation suggest, however, that in any further extensions it should be considered whether or not it would be wise to apply motor power to the cars in the outlying districts instead of equipping an overhead system. The heavy expense of renewing the tyres would be done away with, owing to the lines being laid.

Cardiff.—At the meeting of the Corporation Councillor Courtis moved that the borough treasurer pay monthly into the insurance fund 1¼ per cent. out of each day's gross traffic tramway receipts. Councillor Ramsdale pointed out that they had paid £3,000 for accidents. He was of opinion the amount should not be less than 2 per cent. Councillor Courtis replied that the present year had been quite exceptional, that they had accumulated a fund of £5,000, that during the past three years their expenditure on this account had been £2,382. 4s. 2d., or, roughly, an average of £800 a year, and that the committee felt under the circumstances 1¼ per cent. would be ample. In the first years of a tramways undertaking the expenses on account of accidents were always heavy, but as the years went on experience showed the number of accidents decreased. The motion was adopted.

Finchley.—At last week's meeting of the Urban District Council the surveyor reported that he had received an urgent request from the county surveyor that the plan of the light railway might be approved at once, and a plan was submitted showing the position of the track from the termination of the existing railway to the Barnet boundary. The Highways Committee reported that, with a view to expediting matters so that action might be taken by the County Council before their summer recess, they had instructed the surveyor to forward the plan to the county authorities approved on behalf of the Council to a point by Wallfield Cottage, subject to the paving of the margins of the track being carried out as the work of laying the railway proceeded. The committee also reported that it was not possible to deal with the proposed railways beyond Wallfield Cottage pending satisfactory settlement of the negotiations for widening as far as the Barnet boundary. The committee's action was approved.

Hull.—At the meeting last week of the Tramways Committee, the City Engineer submitted a letter from Messrs. Lackenby and Co., stating that they had delivered the last car cover of their contract to the depôt for fixing, and asked if the Corporation were prepared to proceed with a further number of coverings. The City Engineer said it was a question of whether they should adopt further coverings with opening roofs, or whether as an experiment they should try a cover with a fixed roof and opening side windows. It was decided to reply to Messrs. Lackenby and Co. that the Corporation do not propose at present to fix any further quantity of coverings of the description which they have been providing, and the city engineer was authorised to fix to one of the cars a sample cover with fixed roof and movable side windows. The tramway manager (Mr. W. McCombe) reported that the tramway receipts from April 1, the beginning of the Corporation financial year, to July 29, amounted to £37,387. 7s. 6d., which was an increase of £88. 0s. 10d. over the corresponding period of last year. The Mayor remarked that the great drawback to the system at the present time was the Hedon-road route, which, however, is showing signs of improvement.

Halifax.—The extension of the tramways to West Vale was formally opened last week by the mayor of Halifax, Alderman Enoch Robinson. On the previous day the new route was officially inspected by Lieut.-Colonel Druitt, on behalf of the Board of Trade, and passed by him. The extension measures 1 mile 3 furlongs 7 chains, and the 1d. stage has been altered to a point opposite the Prince of Wales Hotel. The doubling in Huddersfield-road amounts to 1 furlong 5 8 chains, from Stafford House to the top of Salterhebble-hill. The cost was £12,590 for the length from the top of Salterhebble-hill to the terminus at West-vale, and the doubling has entailed an expenditure of £1,082. These figures are less than the original estimate, which was £1 200 for the doubling and £13,543 for the new track. The line from the top of Salterhebble-hill is practically a double one, and included in the cost is the lowering of the road 2ft. 4in. under the railway arch so as to get headway. A private car left the town hall at 4 o'clock on Thursday week, and was joined by two others at Wards-end. The mayor was joined by the chairman of the Tramways Committee, Alderman T. Hey, Councillor Fawcett (vice-chairman), and the rest of the members, Mr. J. Lord (borough engineer), Mr. W. M. Rogerson (electrical engineer), Mr. F. Spencer (tramways manager), and others.

West Ham.—The report of the Corporation tramways for the year ending March 31 shows that the revenue derived from the electric tramways was approximately £55,000, and this amount was increased to nearly £62,000 by the receipts from the North Metropolitan Tramways Co. The working expenses of the electric trams amount to £37,851, and interest on capital absorbs £9.020, while sinking fund accounts for £4,325, leaving a net balance of £10,092. Of this last-mentioned amount £3,092 is allocated to reserve, while the substantial sum of £7,000 is contributed to the relief of rates. The following statistical information in regard to the electric lines is interesting: car miles, 1,237,165; passengers carried, 15,773,592; total number of units used, 1,311,865; units per car mile, 1·060; percentage of working expenses to receipts, 67; average traffic revenue per car mile, 10·68d.; average car miles per day per car, 105; average time-table speed per hour, 6¾ miles; average car hours per day, 16; average working expenses per car mile excluding power cost, 5 646d.; average working expenses per car mile including power cost, 7·343d.; average fare charged per mile, ·56d. Penny fares represented over 56 per cent. of the receipts. At the commencement of the financial year the system (reckoned as single line) represented 17 miles. During the year extensions aggregating no less than 41 route miles were opened. The population served is about 300,000. The tramways department and Mr. H. E. Blain, the manager, are to be congratulated upon these promising results.

Lancashire and Yorkshire Railway.—At the half-yearly meeting on Wednesday the chairman stated that the electric service upon

Digitized by Google

the Liverpool, Southport, and Crossens line during the last six months had been quite satisfactory, and had been appreciated by the vast majority of the people who had used it, as the company had carried no less than 600,000 additional passengers with ordinary tickets. Their season tickets had also increased in number. The amount of building which was going on upon the line in consequence was also very gratifying, showing that it had done what was hoped it would do in attracting a large number of people to go and live out in this district. As to the cost of working, they had only had six months' experience as yet of the complete electric service, and the directors thought they would be better able to judge of the actual facts as to cost of working when they had had a complete 12 months' experience of operation. It was, however, clear that it would have been impossible to give the public the great advantages which they had in rapidity and frequency of service by any other method than by working electrically. There were, in addition, other indirect advantages to be considered; one, particularly, was the reduction of operations necessary at the terminal station, as the train could leave the platform it arrived at without any shunting, and this alone would postpone the necessity for enlarging the Liverpool station for some time to come. The short connecting line between Seaforth and the Liverpool Overhead Railway was brought into operation on July 2, and this additional convenience to the public would no doubt develop in time into an important feeder.

LIGHTING AND GENERAL.

Finchley.—The Urban District Council have agreed to expend £214 on laying cables.

Ashton.—The Guardians have agreed to borrow £5,000 for the purpose of electric lighting.

Islington.—Sanction has been received to the borrowing of £4 885 for electric lighting purposes.

Longton.—The output of electricity during July was 4,502 units, being an increase as compared with last year of 14 per cent.

Buralem.—Application is to be made for sanction to borrow the sum of £5 500 for the purpose of extending the electric lighting mains to Tunstall.

Huntingdon.—The preliminary report of Mr. F. W. Warden-Stevens upon the proposed electric lighting of the borough has been referred to the Public Health Committee for a report.

Brampton.—The Post Office authorities have obtained the Urban District Council's consent to the placing of an underground telegraph line along the road from Castlecarrock to Jockey Shields.

Gomersal.—An offer of the Electrical Distribution of Yorkshire, Limited, with regard to inclusion of the district in an application for a provisional order is before a committee of the Urban District Council.

West Auckland.—At a recent meeting of the ratepayers it was decided to accept the Cleveland and Durham Electric Power Co.'s offer to light the village with 55 16-c.p. electric lights for the sum of 37s. 6d. per lamp.

W. T. Henley's Telegraph Works Co.—The directors have declared an interim dividend on the ordinary shares at the rate of 10 per cent. per annum, less income tax, for the half-year ending June 30 last, payable Sept. 1.

Outing.—The staff of F. A. Glover and Co. celebrated their annual outing on Saturday by an early excursion to Margate, and a cricket match (Mr. F. A. Glover's XIII. *v.* Mr. R. H. Hayne's XIII) at Thanet College ground commenced at 10 a.m.

Agency.—Messrs. Dorman and Smith, of Ordsal Electrical Works, Salford, have appointed Messrs. Andrews, Davidson, and Co., of 136, Bothwell street, Glasgow, to represent them in Scotland for the sale of their switches, fuses, switchboards, electrical accessories, and fittings.

London Gazette.—The first meeting in the estate of John Weston Martin and John Primmer Poor, jun., electricians, 186, New-road, Buckland, Hants, will be held at the Official Receiver's Offices, Cambridge Junction, High-street, Portsmouth, on Aug. 14, at 2 30 p.m.

Removal.—Messrs. Alfred Dickinson and Co., consulting engineers, have removed their London offices to 210, Gresham House, Old Broad-street, E.C., where Dr. John Mannheim is in daily attendance, and Mr. Alfred Dickinson on Tuesdays and Wednesdays, or by special appointment.

Tunbridge Wells.—Owing to the number of houses now requiring a supply of electric light in Camden Park all the house transformers will be moved, and a low-tension 05 distributing main will be laid, which will take its supply from a transformer pillar situated alongside the entrance gates to Camden Park.

Rochdale.—The discounts proposed to be allowed on electricity accounts will amount to £125 for the year, and the reductions in the charges for current for power purposes will represent a sum of £270. Both the discounts and the reduced charges are being made with the object of stimulating the demand for current.

Morley.—The total output from the electricity works during the month of June was 4,742 units, as compared with 5,895 units the corresponding month of last year, being a decrease of 1,153. The actual units sold to consumers by meter were 3,328 against 2,563 the same month last year, being an increase of 765. The number of lamps connected to date was 12,739.

Metropolitan Asylums Board.—The Local Government Board have sanctioned the proposal to enter into a contract with a selected firm or firms for the installation of electric lighting, telephone, and fire-alarm systems at the South-Eastern Hospital without first advertising for tenders, and promising to issue an order authorising the expenditure of a sum not exceeding £2,950 on the proposed alterations and additions to Millfield.

Carnarvon.—The Council in their contracts with the National Electric Construction Co. for the work and extension of mains have exceeded their borrowing powers by about £344, and application will be made for sanction to borow a further £1,000. Applications for 108 8-c.p. equivalents and promises of a further seven 8-c.p. equivalents have been received from persons in Palace-street, and an extension is to be made at a cost of £92.

Lifts.—In a small illustrated pamphlet the London Hydraulic Power Co., 9, Bridge-street, S.W., give a short summary with regard to the safety, convenience, and economy of their lifts, and they illustrate progress they have made since 1886 by a table which shows that in that year they delivered 1,271,000 gallons of water for 364 machines at work, and that these numbers had increased in 1905 to 17,708,000 gallons and 5,597 machines. Over 150 miles of mains are at present laid for the above purposes.

Perth.—The electricity accounts for the year ending May 15 show a revenue of £5,484 and expenditure £3,354, leaving £2,130 to be carried to the net revenue account. Interest on the sinking fund and reserve fund amount to £2,422. The assets are entered at £43,292. During the year 629,209 units were generated; there were 159,120 units used in public lamps, 358,100 units by private consumers, and 57,271 units in works giving a total of 574 491 units. There were 70 arc lamps and 59 incandescent pillars for public lighting, and the maximum supply demanded was 421 kw.

Bexley.—At a recent public meeting of the inhabitants of the district a resolution was passed protesting against the action of the Bexley Urban District Council "in agreeing secretly and without consulting their constituents to sell to the electric power monopolists the power station at Bexley at considerably less than cost price, and to buy from them power for the tramways and lighting at almost twice the price offered to private manufacturers, thus betraying the interests of the community and helping on the establishment of a trust in an industry of paramount importance."

Hull Municipal Telephones.—At the recent meeting of the Corporation Telephones Committee, which was held *in camera*, a letter from Mr. Bennett with reference to the construction of the overhead work was referred to a sub-committee, consisting of the chairman, deputy-chairman, and Messrs. Holder, Boyes, Bentham, and Hanger, with full power to deal with it. The telephone manager's recommendation that the committee should instal party lines for five subscribers at £3 per annum per subscriber for 720 messages, and after that number of messages at 1d. per call, was adopted.

Ramsey.—At the last Urban District Council meeting the clerk read a letter from Lord Stanley to the Right Hon. A. E. Fellowes, M.P., as to the provision of telephonic communication for the town. It was stated that to put Ramsey into telephonic communication with the trunk system would entail a somewhat costly circuit to Huntingdon, and in order to justify the expenditure it would be necessary to get 20 persons to rent exchange circuits at the rate of £6 a year for a connection to premises within half a mile of the exchange, with an additional 25s. for each quarter of a mile after the first half-mile.

Yarmouth.—The Stables Committee have resolved to purchase an oat and bean crusher to be worked by motor at a cost of £40. Nineteen applications have been received for electric light, estimated to bring in a revenue of £130, for which cables are to be laid at a cost of £530. The town clerk has been instructed by the Law Committee to serve notice on the National Telephone Co., under the several agreements between the Corporation and the company, requiring the removal at the expiration of six months' time of all posts now erected on the highways in the borough and on corporate property.

Redditch.—Compared with the previous 12 months the progress made by the electric supply undertaking in the past 15 months had been very satisfactory. On Jan. 1, 1904, the total number of consumers was 296. On March 31, 1905, the number was 383. On Jan. 1, 1904, the total lamp connection in 8-c.p. lamps was 15,844; on March 31, 1905, it was 23 345. The gross profit on the 15 months' working was £783, an increase of £323 over that obtained in 1903, and equal to a dividend of 2½ per cent. on the capital expended at the beginning of 1904. The analysis of the works costs shows that in the past 15 months the total cost per unit had been reduced from 2·07d. to 1·67d.

Stock Exchange.—The Stock Exchange Committee have appointed Aug. 16 special settling day in American Telephone and Telegraph Co.'s 3,980,000 dol. 4 per cent. collateral trust bonds of 1,000 dol. each, allotted in London, Nos. 55,732 and 55,733, 56,551 to 56,900, 57,401 to 57,486, 58,633 to 58,657, 61,848 to 61,880, 61,929 to 61,931, 62,369 to 62,383, 66,002 to 66,267, 66,526 to 67,000, 67,251 to 67,745, and 67,751 to 69 980; and Aug. 23 for Metropolitan Electric Tramways' 182,181 ordinary shares of £1 each, fully paid, Nos. 1 to 40,785 and 249,942 to 391,337. The committee have ordered Edmundson's Electricity Corporation's further issue of 10,000 ordinary shares of £5 each, fully paid, Nos. 70,001 to 80,000, to be quoted in the official list. Applications have been made to the committee to appoint a special settling day in and to grant a quotation to London United Tramways (1901) further issue of £300,000 4 per cent. first mortgage debenture stock; and to allow the following securities to be quoted in the official list: Marconi's Wireless Telegraph Co.'s shares of £1 each and Metropolitan District Railway Co.'s further issue of £100,000 4 per cent perpetual debenture stock.

Dalkeith.—The Electric Supply Corporation have concluded an arrangement with the Town Council to erect Nernst all-night lamps on the alternate arc lamp columns in a number of streets. These will be lighted when the arc lamps are put out for the night. The Corporation have fixed £2 each per annum as the cost for the light, and the fitting of the lamps and upkeep are undertaken by the contractors. A scheme of electric lighting for the less important streets is under the consideration of the Lighting Committee of the burgh, and they have recommended to the Town Council a scheme which works out,

Digitized by Google

including the laying of the mains, at £2. 7s. 6d. per year for each light.

Blaydon.—The Urban District Council have concluded a draft temporary agreement with the County of Durham Electrical Power Distribution Co. to enable the company to start with the works at once, subject to certain reservations that the company and the Council should enter a contract under Section II. of the Electric Lighting Act, 1882, for the execution and maintenance of the works needed within the area of the provisional order, and that the period of such contract should expire at the end of 25 years from the date of the temporary agreement. Application is to be made to the Board of Trade "enabling them to carry their high-tension and distributing mains overhead, but that the Council still reserves the right to approve of the design and position of the poles for carrying the wires."

Felten und Guilleaume-Lahmeyerwerke.—We are informed that the agency for Great Britain and Ireland for insulated wires and cables for electric light and power purposes and for the Neptune copper rail bonds manufactured at the Mülheim works (Carlswerk) of Messrs. Felten und Guilleaume-Lahmeyerwerke, have as from Aug. 1 been transferred to the Lahmeyer Electrical Co., 109 and 111, New Oxford-street, London, W.C., and that their English chief electrical engineer (Mr. R. R. Todd) has joined the Lahmeyer Electrical Co from that date as manager of their cable department. The agency for telephone and telegraph wires and cables, as well as for all bare iron, steel, copper, and bronze wires for all purposes, and their numerous other wire manufactures—such as wire ropes, wire netting, barb wire, wire chains, wire mats, etc.—will remain with Messrs. W. F. Dennis and Co., 49, Queen Victoria-street, London, E.C., as before.

Dewsbury.—The accounts of the electricity department show a gross profit of £4,384. After allowing £356 for discount and leakages, the income from the sale of current amounted to £8,922, and sundry other receipts brought the total up to £9,243. The chief items of expenditure were £3,089 for the generation of electricity and repairs and maintenance; £602 for distribution; and £830 (including £285 transferred to joint expenditure account), management expenses. From the net revenue account it appears that £1,329 was paid in interest; £1,821 contributed to the sinking fund; £1,000 applied in aid of the rates; and £250 transferred to the reserve fund, still leaving a balance of £1,002 to carry forward. These figures total £5,403, which represents the income, made up as follows: balance from last abstract, £1,009; balance from this year's revenue account, £4,384; and bank interest, £9. The reserve fund now stands at £798.

Eastbourne.—Mr. J. Kempe Brydges in his annual report states that the units sold for private lighting were 753,562, as against 714,716 last year, and for power 34,423, against 18,686. The following figures are available: number of consumers connected, 1903-4 888, (1904 5 977); added during year, 84 (89); units sold, 897,193 (947,671); net balance, £3,858 (£2,726); allotted to depreciation fund £1,000 (£2,000); allocated to relief of rates, £750 (£725). The cost of working the undertaking has been reduced, the total cost per unit sold being 1·95d., as against 2·09d. last year, and 3·57d. when the Corporation first acquired the undertaking. Owing to the reduction in the price the revenue has fallen from 5·61d. to 5·1d. per unit, and the net profit has fallen from 1·03d. to ·69d. per unit. The coal bill has been slightly reduced, although the cost of coal per ton was 1s. 2d. more than last year. It is hoped that the introduction of the mechanical stoker, combined with the lower price of coal, will considerably reduce this item during the current year.

Kensington.—The Works Committee intimated at the last Borough Council meeting that they had had before them the further communication which had been received from the Kensington and Knightsbridge Electric Lighting Co. on the subject of the extension of the use of electricity for street-lighting purposes, stating that if the Council could see their way to light the side streets in the borough by this means, they would be prepared to supply the current for the purpose at 1d. per unit subject to the average lighting time per lamp being 3,600 hours per annum. The company also call attention to the suitability of Nernst lamps for lighting side streets by electricity, and stated that in the event of the Council being desirous of inspecting this kind of lamp they would be prepared to fix up three or four such lamps free of charge. A recommendation "that the company be informed that the Council are not prepared to adopt the proposal put forward at the present time," was agreed to. It was explained that the company's offer seemed to be made on the condition that the whole of the side streets were lighted by electricity.

Colchester.—The electrical engineer's last report states that the output of electricity (lighting) in units during June was 19,403 against 16,338 in 1904 and 15,113 in 1903; ditto (traction) ditto 38 931; number of consumers at end of June, 722 against 481 in 1904 and 362 in 1903; total number of 8 c.p. lamps connected 33,558, against 25 881 in 1904 and 22,819 in 1903. The Electric Light and Power and Tramways Committee having considered the report of the electrical engineer dealing generally with the question of cost incurred in generating electric current for tramway purposes, have made the following recommendations, which were adopted by the Council last week: to rescind its decision arrived at on May 3 last relative to the price of such current supplied during the said eight months, and in respect of the supply for the financial year ending March 31, 1906; (2) to fix the price of current so supplied during the said eight months at 1½d. per unit; (3) to direct that the question of price for the financial year ending March 31, 1905, be considered by the joint committees previously to the completion of the next annual accounts of the electric light and power department, the tramways department in the meantime to pay on account for current at the same rate—viz., 1½d. per unit—the payment to be subject to any needful adjustment after conference.

Willesden.—The accounts of the Urban District Council's electricity undertaking for the year ended March 31, 1905, show that the total number of consumers at the commencement of the year was 557, and at the end 1,002. The equivalent number of 8-c.p. lamps connected at the commencement of the year was 29,462, and at the end 49,300. The total increase in 8-c.p. lamps connected during the year amounts to 60 per cent. The revenue amounted to £13,301, and the expenditure on revenue account, including sinking fund charges, was £13 037, showing a profit on the second year's working of £204, as against a deficiency on the first nine months' working of £4. The expenditure included a sum of £334 legal charges incurred in the proceedings instituted against the Metropolitan Electric Supply Co. The report draws a comparison between the present mode of purchasing electricity in bulk and of generating the supply. The charges to consumers have been reduced both for lighting and supply for motive power, with the result that the average price received for private supply has been only 3·61d. per unit during the past year as against the first estimate of 4·61d., a reduction of nearly 20 per cent. As only 6 per cent. of the 874,914 units sold to private consumers was used for motors and heating, the average price for lighting is among the lowest received, not only in the Metropolis, but in the whole country. Notwithstanding the total average revenue per unit sold was only 3·64d., the year's working has resulted in a net profit, as before stated, of £204 after paying all charges. The low average price obtained has correspondingly affected the rate paid for bulk supply, which, instead of amounting to 2 231d. per unit sold, as originally estimated on a closely similar output, was only 1·5981d. per unit sold, or ·6331d. less. If the surplus in any year exceeds 5 per cent. upon the aggregate capital expenditure, a rateable reduction is to be made in the charge for the supply of energy. The Council already have a reserve in the profit of £3,300 received from the power company, and this may be applied in the purchase of sites for generating and sub-stations should the agreement with the company for bulk supply be terminated at any future date.

Bermondsey Inquiry.—The Bermondsey Municipal Association last week passed a resolution to the effect that the Board of Trade be asked to hold an inquiry into the electricity undertaking of the Council, and that a full copy of the committee's report be forwarded to that authority. The report referred to is one prepared by a committee of inquiry into the municipal electrical undertaking at Bermondsey which was appointed at a meeting of ratepayers last December. It deals principally with three points—namely, the loss on the dust destructor, the cost of electric street-lighting, and the system of accounts under which it is alleged that items are deliberately transferred to a purely administrative department, although they legitimately belong to the electric lighting undertaking—for instance, probably about £1 000 this year as parliamentary expenses. With regard to the actual cost incurred in erecting and working the destructor, the committee say: "From the borough treasurer's accounts for the year ending March 31, 1904, we find that the capital cost was £25,000; working and maintenance for 1904, £5,675. 8s 1¾d. The revenue was: supply of steam to baths, £300; supply to electric lighting, £500; sale of flue dust, £38. 1s. 1d.; destruction of trade refuse, £31. 15s. 1d.; insurance claims paid in respect of accidents to workmen, £16. 16s. 2d.—total, £886. 12s. 4d. Actual cost for the year, £4,788. 15s. 9¾d. The amount of refuse actually treated was 13,027 tons, and the cost of barging this at 2s. per ton would have been £1,302. 14s., so that the realised loss for the year was £3,486. 1s. 9¾d. It thus appears that the actual cost for destroying 13,027 tons of refuse was £4,788. 15s. 9¾d., or 7s. 4d. per ton, and the actual loss was £3,486. 1s 9¾d. In these figures no allowance is made for depreciation. If this is put at a very low estimate of 1½ per cent. on the cost price, £25,000, we shall have to add £375 to the net cost and to the actual loss for the year, thus bringing the net cost to £5,163. 15s. 9¾d., and the realised loss to £3,863. 1s. 9¾d." The committee compare the estimates and the actual result as follows: capital cost, estimate £10,000, actual result £25,855; maintenance, estimate £1,359. 4s 8d., actual result £5,675. 8s. 1¾d.; revenue, estimate £1,170, 1s. 8d., actual result £886. 12s. 4d.; cost for the year, estimate £189. 3s., actual result £4,788 15s. 9¾d.; cost of destroying refuse per ton, estimate 4d., actual result 7s. 4d.; net annual profit, estimate £786. 15s. 4d., actual result no profit, but instead a loss of £3,486. 1s. 9¾d. Concerning the electric light undertaking, the report points out that the ratepayers occupy a three-fold position: (1) that of sellers of means of production, (2) that of producers, and (3) that of consumers, and that it is, therefore, a palpable absurdity to contend that the whole undertaking is a financial benefit to the ratepayers, because one branch shows a balance, by allocating many of its own debits to one of the other two branches, and by exacting from the other an excessive charge. The report gives an analysis of the actual number of units produced during the year ended March 31, 1905: (1) to private consumers of electricity for lighting purposes; (2) to private consumers for power purposes; (3) to municipal institutions; (4) to the municipal authorities for street-lighting purposes; the expenditure occasioned thereby, and the amount realised by the sale. This analysis shows that the sale to private consumers results in a loss amounting to £203. 3s., but that the sale for public purposes—*i.e.*, by the ratepayers as producers to the ratepayers as consumers—realises by the fixing of an arbitrary figure a surplus of £1,000. The report shows how this £1,000 surplus, or net profit, as it is wrongly called in the accounts, is made. The report further complains that no reduction of price similar to that made to outside consumers is made in street-lighting, and the supply to municipal institutions, and that in consequence the revenue account is unduly inflated, also that whereas for the purposes of street-lighting £5,413. 9s. 6d. has been spent in the erection of arc lamps, the electric undertaking is not charged with one penny of the same. Similar remarks are made with regard to maintenance of arc lamps. With regard to the Council's estimates for the current year, which are based on reduced prices for current to outside consumers, the committee consider that Bermondsey possesses none of the characteristics

Digitized by Google

which give a practical encouragement to an electric undertaking. They say: "(1) There are very few residences of any size in the borough, and no large retail establishments; (2) the large buildings are principally warehouses, which require, comparatively speaking, very little electricity for lighting purposes; (3) powers are refused to the undertaking by the Board of Trade in the part of Bermondsey in which customers would be most probably found, and are only conceded in that part which private companies apparently avoid as unprofitable." The committee thinks that the consumption of power may increase, but that three points must be noted: (1) the competition of the gas company, which supplies motor energy at a very low cost; (2) the fact that many large consumers generate their own electricity by means of energy supplied by the gas company; and (3) that the cost to such customers does not exceed 1d. per unit. Even if all the advantages were allowed—of not paying the complete instalments, of not taking into consideration the dust destructor deficit, of transferring accounts to other departments, and in the face of keen competition realising the large estimated increase—the profit as shown by the undertakers would only amount to 0·401 of 1d. per unit as far as motor power was concerned. To spend capital on generation of motor power, and to maintain the dust destructor for such generation, did, they consider, constitute a lamentable policy. A comparison is made with other districts, and the report concludes as follows: "It is generally agreed that the Camberwell area is one of the, if not the, best lighted in London. In the main thoroughfares burners of 80 c.p. are fixed, in the semi-main roads 60 c.p., and in all other 40-c.p. burners. The entire cost of public lighting for the year ended Lady Day, 1904, as shown in the Council's published report, was £11,752, an average of £90·8 per mile, the figure for the year to March last being lower. During the year ended Lady Day last Bermondsey for gas used in public lighting £3,753 and £4,738 for electricity, averaging £123. 1s. per mile. If the Camberwell system was in operation in Bermondsey a saving of about £2,200 per annum would be effected, with this additional advantage, that there would be a full efficiency of street-lighting throughout the night. One very great objection to the electric light for the streets is the obligation to turn them off at midnight, leaving the streets, by reason of the ineffective substitute provided, in comparative darkness. After 12 o'clock, in spite of the excessive cost of street-lighting, Bermondsey is the worse-lit district in the Metropolis."

PROVISIONAL PATENTS, 1905.

JULY 28.

15479. A contact hood for use in raising and lowering electric arc lamps and other apparatus. Claude Edward Gillett Gilbert, Chingford, Essex.

JULY 29.

15546. Improvements in apparatus for controlling and operating the points of electric railways and tramways. William Herbert Turner, Rowland Edward Dixon, and Thomas Bell Stewart, Swinegate, Leeds.

15561. Improvements in the production of metal articles or metal-covered articles by electro-deposition. Frank Iorns Gibbs, 128, Colmore-row, Birmingham.

15577. A new or improved cut-out for overhead tramway wires. Frederick Charles Morris and James Oliver Hart, 8, Quality-court, Chancery-lane, London.

15590. Improvements relating to points or switches for electric tramways working upon the slot-conduit system. Albert Newmann-Connett, 322, High Holborn, London. (Complete specification.)

15591. Improvements in devices for electromagnetically influencing the arcs of electric arc lamps working with alternating-current. Tito Livio Carbone, 322, High Holborn, London. (Complete specification.)

15594. Improvements in the conveying of currents to electrodes arranged in electrically-insulated tubes. Ganz und Co., Eisengiesserei und Maschinen-Fabriks Act.-Ges. m. b. H., 6, Lord-street, Liverpool. (Date applied for under Patents Act, 1901, Aug. 26, 1904, being date of application in Germany.) (Complete specification.)

JULY 31.

15606. Improvements in the manufacture of metal articles by electro-deposition. Frank Iorns Gibbs, 128, Colmore-row, Birmingham.

15658. Improvements in and relating to telephone attachments. Nebo Earl Damico, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

15673. Electric lamp bulb and method of and apparatus for finishing same. George Philip McDonnell, 55, Chancery-lane, London. (Date applied for under Patents Act, 1901, Nov. 2, 1904, being date of application in United States.) (Complete specification.)

AUG. 1.

11301a. Improvements in mounting and heating cylindrical thermo-electric generators. Compagnie Thermo-Electrique (Système Hermite) Société Anonyme, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 3, 1905, being date of application in France. An invention comprised in Application No. 11,301, dated May 30, 1905.) (Complete specification.)

15681. Improvements in electric rotary switches or wipe contacts. Samuel Hindley, 78, Langdon-street, Sheffield.

15690. An improved system of electric road traction. Alfred Lyster Shepard, 32, Victoria-street, Westminster, London.

15714. Improvements in testing apparatus for traction insulators. Arthur Henry Pott and Kenelm Edgcumbe, Collindale Works, Hendon, London.

15739. Antiseptic mouthpiece or transmitter for telephone or speaking tubes. Joseph Vyvyan Wedgwood, The Wigwam, Aldwick, Bognor.

15752. Improvements in self-releasing brake handles for electric tramcars and other vehicles. Marius Belmondo, 6, Lord-street, Liverpool. (Complete specification.)

15769. Improvements in electric soldering irons. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

15770. Improvements relating to the insulation of electric conductors. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

AUG. 2.

15791. Improvements in the operation of points or signals for electric railways. George William Somerville and Oliver Hicks, 68, Owen-street, Accrington.

15819 Apparatus for electrically ringing church bells and the like. John Richardson Eyre and Edmond Meyer, Tudor Boddam, 28, Marlborough-hill, London.

15819. Improvements in and relating to automatic electric circuit breakers. Lionel Robinson and Co., Limited, and John Dingle Adams, 28, New Bridge-street, London.

15827. Improvements in electrical carbon brushes and in holders for same. Frederick James Hesmes Baker, 33, Cannon-street, London.

15836. Improvements in electric wiring. Reginald Frederick Yorke, 19, Holborn-viaduct, London. (Complete specification.)

15859. Improvements in prepayment meters. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States).

15860. Improvements in dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

15862. An improved electric press for bells. Frederick Fenwick Robinson, Royal Oak, Sawley-road, Long Eaton, Derbyshire.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Aug. 24.

1904.

15469. Use of vapour electric conducters in distributing systems for rectifying or other purposes. Kruh. (Date applied for under International Convention, July 13, 1903.)

16842. Electricity service systems and junction boxes therefor. Owen.

16932. Electromagnetic brakes for vehicles. Kramer. (Date applied for under International Convention, Aug. 7, 1903.)

16968. Arc lamps. Cook. (Post-dated Sept. 13, 1904.)

16978. Means for receiving or translating electric, wireless, or like impulses. Underhill.

17043. Electric bells, indicators, and domestic telephones. Bhisey.

17060. Magnetic compasses. Morrall.

17442. Electric controllers. Scott.

18203. Electric motor control systems. British Thomson-Houston Company, Limited. (General Electric Company.)

18204. Transformers especially adapted for use on electric vehicles. British Thomson-Houston Company, Limited. (General Electric Company.)

19160. Telephone cord. Sievert.

19506. Wall sockets and switches for electric circuits. Fletcher.

20715. Insulating edgewise-wound electric coils. British Thomson-Houston Company, Limited. (General Electric Company.)

20965. Leading-in conductors for electric incandescent lamps and the like. Carolan. (General Electric Company.)

20976. Electric traction. Clouston.

21028. Electrical measuring instruments. Elphinstone and Fast.

21043. Alternating-current electric motors. Carolan. (General Electric Company.)

21307. Electric energy meter. Javaux.

21672. Electric batteries. Lake. (Soc. Anon. Le Carbone.)

22372. Means for trolleys or vehicles to pick up and return electric current from and to conducters they traverse and obtain motion. Sayer.

1905.

1004. Dynamo-electric machines. Brown and Greenwood.

Digitized by Google

369. Vapour electric apparatus for rectifying alternating electric currents and other purposes. Jackson. (Date applied for under International Convention, Jan. 9, 1904.)

3979. Supporting devices for electric conductors. Jones. (Date applied for under International Convention, March 14, 1904.)

4363. Apparatus for obtaining constant voltage from dynamos working at varying speeds. Ejquem. (Date applied for under International Convention, March 3, 1904.)

5409. Vapour electric apparatus. Hewitt. (Date applied for under International Convention, April 9, 1904.)

5553. Electric arc lamps. Riley and Rowing.

8659. Means for protecting electric telegraph lines against the influencing action of alternating-current lines situated in the neighbourhood thereof. Siemens Bros. and Co., Limited. (Siemens-Schuckertwerke G. m. b. H.)

8973. Vapour electric apparatus. Hewitt. (Date applied for under International Convention, May 13, 1904.)

9129. Thermal electric switches for incandescent electric lamps. Frey. (Date applied for under International Convention, Aug 3, 1904.)

10111. Insulation of electric conductors. Berger. (Date applied for under International Convention, May 14, 1904.)

10769. Receiver connections for wireless telegraphy. Thompson. (Ges. für drahtlose Telegraphie m. b. H.)

13084. Controllers for single-phase induction motors. Jackson. (Date applied for under International Convention, June 30, 1904.)

14214. Electric furnaces. Kjellin. (Date applied for under International Convention, July 11, 1904.)

14221. Means for producing current or radiations for a transportable wireless transmitter station. Thompson. (Ges. für drahtlose Telegraphie G. m. b. H.)

NOTES.

Electro-Peat.—It is reported that a plant for the manufacture of electro-peat fuel has been erected at Kiberry Bog, near Athy, County Kildare, upon the estate of the Duke of Leinster, and that it will be in operation before the end of the present month.

New Publication.—The latest of the "Model Engineer Series," issued at 6d., by Messrs. Percival Marshall and Co., is, "Screw Threads and Twist Drills (Small Sizes)," by George Gentry. The handbook contains definitions and tables of a number of types, including the Whitworth, British Association, and the International Metric Standard, but we must confess to a feeling of surprise that no allusion whatever is made to the work of the Engineering Standards Committee on the subject.

Submarine Signalling.—At the instance of Trinity House the first experiments to be made in England with the apparatus for the transmission of submarine signals which has been perfected by Mr. Millet, of the Submarine Signal Co., were last week conducted in the Straits of Dover. The system has been successful in its trials at the lightships outside New York. By means of the signals, steamers approaching New York have been enabled accurately to ascertain their position as much as four and five miles away in thick fog. The vibrations travel under water over four times faster than in air. The experiments in the Channel last week are stated to have been successful.

American Apprentices.—The General Electric Co. announce that assistants are required at its factory in West Lynn, Mass., and the following rates of pay are offered. Drawing office apprentices, who must have graduated at a high school, commence at 22s. per week, and advance by half-yearly increments to double that amount in three years, at the expiration of which they receive a bonus of £15 if their services have been satisfactory. Shop apprentices who are graduates of high schools begin at 18s. 6d. and advance to £2, with a bonus of £22 at the end of four years. Grammar school graduates or high school students receive for the latter class work 14s. per week, advancing to 35s., with a bonus of £22 at the end of four years. It will be noticed that no premium is required from those entering the works.

The Production of Iron Mirrors.—A method of producing light iron mirrors for galvanometers is described by Mr. V. Bierwicke in *Annalen der Physik*. An iron strip capable of being electrically heated to redness is arranged in an air-tight glass vessel. Immediately over the strip is suspended the material (glass, mica, or celluloid) on which the mirror is to be deposited. The containing vessel is then highly exhausted by means of a mercury pump, and when a pressure of only a few thousandths of a millimetre is reached the iron strip is raised to a bright red heat, and the deposition of iron commences. The deposit maintains its good reflecting qualities for a long period; it appears perfectly coherent under the microscope, and is capable of retaining a high degree of residual magnetism. In this way the mirror can be employed as its own magnet in place of heavy cut-steel mirrors. The reflecting power of these mirrors for white light is about 62 per cent. of that of a silver mirror.

Electricity in Mining.—At the Mining Congress recently held at the Liége Exhibition, Mr. L. Creplet, engineer of the Société International d'Electricité, Liége, advocated the use of continuous-current motors for driving roll trains. There are already several applications in Belgium. The Grievegnée Company uses a merchant mill driven by a compound-wound motor that can develop from 450 h.p. to 900 h.p., and the Providence Company has another capable of from 500 h.p. to 1,000 h.p. The Ougrée-Marihaye Company (which has already applied this improvement) will in a few months have in use a roll-train motor of 1,000 h.p. to 1,500 h.p., capable of direct driving at 75 r.p.m. to 135 r.p.m. M. Greiner, general manager of the Cockerill Works, Belgium, stated that the problem of driving roll trains electrically is already solved from an economical point of view, and he expressed the opinion that the best solution is central electric generators driven by gas-engines, and each roll train driven by its own motor.

Production of Tickets.—From time to time railway and tramway companies find their right to call for the production of passengers' tickets questioned before various tribunals by travellers of more or less acrimonious temperament. In general the courts have upheld the validity of the companies' by-law in reference to this matter, and had this not been the case one might well wonder what practical means the companies would have of placing an obstacle in the way of constant fraud by unscrupulous passengers. Seeing, then, that the regulation harmonises with both law and equity it is a matter for some surprise that it should meet with disregard at the hands of a member of the legal profession. This happened the other day when Mr. Herbert Clifford Gosnell, solicitor, refused to produce his ticket, stating that he "could not be bothered." Apparently he made no effort to find it, but considered it less troublesome to hand the inspector his card, with the remark that the company could take out 40 summonses if they liked. For technical reasons the magistrate dismissed the charge as there was a lack of corroborative evidence, but acts like these on the part of a lawyer do not seem precisely the kind of thing to encourage harmonious relations between tramway owners and the community in general.

Patents.—Messrs. Jordan and Sons have just published a treatise on "The Law and Practice Relating to Patents, Trade Marks, and Designs," by Mr. David Fulton, of the Middle Temple. This is the third edition, and has been revised to include the changes introduced in the regulations which came into force on the first day of January. The precedents quoted comprise more than 300 additional cases, some of them of considerable importance. The publication of this edition has been deferred in order that all available information upon the new system of patents examination might be included. A good deal of apprehension was expressed on this score, so it is gratifying to have the author's assurance that the careful and discriminating use of their powers by the Patent Office promises to make the new system a really beneficial one. The present volume is of a comprehensive character, and deals with patent law and practice from every point of view that one can think of. Trade marks and designs are similarly treated, and the appendices contain the text of the International Convention and several useful forms. The treatise (which is priced at 12s. 6d.) is written in eminently lucid terms, and is relatively free from legal verbiage, so that it furnishes a serviceable guide to layman as well as lawyer, and should certainly be of use to the engineer.

The American Institute.—The issue dated July of the *Proceedings* of the American Institute of Electrical Engineers contains the following papers: "High-Power Surges in Electric Distribution Systems of Great Magnitude," by Charles Proteus Steinmetz; "Comments on remarks made by Colonel R. E. B. Crompton before the International Electric Congress at St. Louis," by J. W. Howell; "Water Powers of the South-Eastern Appalachian

Digitized by Google

some justification for such a course. It is a heavily-rated borough, and the tramway system has been constructed upon sound lines, so that in the early years there is not such pressing necessity for making an ample allowance for depreciation, and it must be confessed that, apart from the relief afforded to the rates, it is not every municipal tramway undertaking that can place over £3,000 to reserve in the first year, in addition to carrying passengers at low fares. The population of 300,000 was carried some 52 times during the year, and the average fare worked out at ·84d. The 1d. fares were responsible for over half of the receipts, and the ½d. fares contributed 25 per cent. to them. The 1½d. and 2d. stages were little patronised, and it is rather surprising to find that "workmen" with cheap tickets were only 1·2 per cent. of the travellers. Taken altogether the West Ham tramways department have good cause to feel satisfied with the results attained, and Messrs. Bullock and Blain, the electrical engineer and tramways manager respectively, are to be congratulated upon the outcome of their efforts.

Patent Practice. — Attention is directed in a paragraph appearing in the Patent Office *Journal* to a recent decision of the Law Officers in connection with Rule 4 of the Patents Rules, 1905. This rule provides that: "The statement of the invention claimed with which a complete specification must and shall be clear and succinct as well as separate and distinct from the body of the specification." The Law Officers intimated that they had no desire to lay down that the number of claims amounts to any infringement, as a specification may justifiably contain a number of separate claims. At the same time, the Law Officers deprecate the American system of attempting to deal with every possible contingency, as this is apt to result in unnecessary copiousness to the detriment of lucidity. A remark made by the Solicitor-General in expressing his concurrence with the views of the Attorney-General, is worthy of reproduction. "I agree that the mere number of claims will not necessarily constitute an infringement of this rule, supposing the claims to be real and substantial; but, on the other hand, although each claim may, in itself, be clear and succinct, if the claims are not really and substantially separate, I think in that case it would come within this rule, and that the claims, taken as a whole, would not be clear and succinct." There is no doubt that in the past the claims appended to the specification have often suffered from excessive verbiage, and this admonition from the Law Officers is a timely one. The *Journal* also calls attention to Rule 14 of the Patents Rules, 1905, which prescribes that "every Convention application, in addition to the specification left therewith, must be accompanied by a copy or copies of the specification, and drawings or documents filed or deposited by the applicant in the Patent Office of the foreign state or British possession in respect of the first foreign application, duly certified by the official chief or head of the Patent Office of such foreign state or British possession as aforesaid, or otherwise verified to the satisfaction of the comptroller." The comptroller has been advised that it is obligatory that the necessary verified documents should be left at the same time as the Convention application, and in future this requirement, is to be rigidly enforced.

The Big Power Scheme.—The metropolitan borough councils owning electrical undertakings, apprehensive of another attempt to formulate a huge private scheme for supplying electricity in bulk, propose to hold another conference with a view to protecting themselves against what they term the monopolists, and a conference under the auspices of the London County Council is also in contemplation. In an interview with a *Daily News* representative Mr. Mills, chairman of the Islington Electric Lighting Committee, stated that the experience gained during the proceedings before the Select Committee would not be wasted, as it had taught the borough councils the importance of combination. He thought the boroughs now realised that they would have to unite to provide power cheaply in bulk. If electricity could be supplied cheaply by a company, it could be supplied cheaply by municipalities. By a new scheme for extending their plant, they in Islington would be able to generate electricity more cheaply than they could have bought it from the Administrative County of London Company. The boroughs were disappointed at the attitude of the Board of Trade, which had quite gone over to the side of the monopolists. Mr. Mills did not think the last had been heard of the promoters, though he doubted whether they would essay such a sweeping scheme again. If the London local authorities can show that they are in just as good a position as the promoters of the Administrative County of London scheme to give a cheap supply of power, they would pretty well dispose of the latter's case, but it can hardly be said that they have shown this to be the case up to the present. From some statements to a representative of the same journal by Dr. T. B. Napier, chairman of the London County Council Parliamentary Committee, it appears not improbable that the County Council may revive its bill for a bulk supply to the metropolis if there is a "tolerably unanimous" request on the part of the borough councils, who would be expected to give a definite assurance that they would take sufficient current to prevent a loss. This scheme would raise again the vexed question of competition between the present supply companies and a municipal authority, which up to the present has not been sanctioned by Parliament. We also doubt if the County Council would be granted powers to go outside their area, as is now proposed.

The Bradford Burn-out.—We regret to note that the electricity supply at Bradford was interrupted last week, due to a fault on some main feeders. On Wednesday, 9th inst., the first indication of the fault was noticed at 5.25 p.m., when arcing occurred between the armour of two of the cables in the basement of the Valley-road works at the point of entry from the roadway. The arcing developed into a short-circuit, which was extinguished with sand. About half an hour after a heavy short-circuit occurred at some point outside the works premises, which caused the automatics of all the machines running on the general supply service, together having a capacity equalling 1,800 kw., to open, thus discontinuing the supply, and attempts which were made to again switch in the machines proved abortive. Smoke issuing from the cable culvert leading into the basement led to the conclusion that the trouble was not far removed from the works, and immediate steps were taken to open up the ground above the culvert, and to remove the cover of the same, which consisted of heavy York flags, some of which weighed as much as three tons. In the meantime the feeders were disconnected from the 'bus bars and from the network and tested, and a sufficient number of healthy feeders coupled up to maintain the load, and the supply was restarted at 9.50 p.m. The remaining feeders found unaffected were coupled up during the night, and the damaged cables repaired and again put into use during the succeeding day. Six cables, having a combined sectional area of 7½ square inches, were affected, several being burned clean through. The most badly damaged portion was found at a point about 60 yards from the works. The cause of the first cable breaking down has not yet been ascertained, but the effect of the breakdown raised

Digitized by Google

the potential of the lead sheathing and armour, and caused arcing from the same to other cables in the same culvert, which eventually burned through the protective sheathing of these, and at last developed into a short-circuit between the various cables affected. A somewhat similar breakdown occurred last December, and under the advice of Mr. Alfred S. Blackman, the city electrical engineer, the Bradford Council recently sanctioned the expenditure of £40,000 for providing new mains and for sectionalising and fusing the network. The work of laying these mains and providing the switchgear is at the present time proceeding with all possible speed. When the scheme is completed a feeder on which a fault develops will be automatically disconnected from the main supply by its fuses, and a similar occurrence to that of last week prevented.

Transformers.—We notice from the *Official* (*Patents*) *Journal* that a patent has been obtained in this country by Mr. J. S. Peck, of Pittsburg, U.S.A., in connection with a type of transformer designed to prevent or lessen the variation in the compounding effect. In a distributing

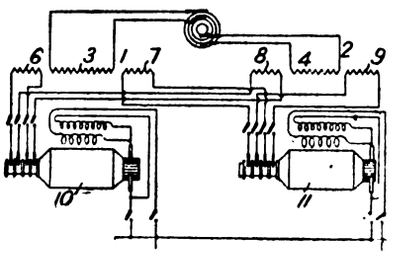

FIG. 1.

system in which transformers and rotary converters supply current to direct-current mains, the transformers are arranged with sectional secondary windings, so wound as to provide for the production, by changes in the number of converters, of either no effect or predetermined effects on the voltage variation of the direct-current circuit. When compounded converters are employed in such a system, the compounding effect—*i e*, the variation in the direct-current voltage due to variation in the direct-current load—varies with the inductive effect of the transformers on the alternating current, and therefore is, with ordinary arrangements of transformers, variable with changes in the number of converters in use. To prevent or lessen this variation, the transformers 1, 2, and the converters 10, 11, may be arranged as shown in Fig. 1, in which the transformer secondaries consist of sections 6, 7, and 8, 9

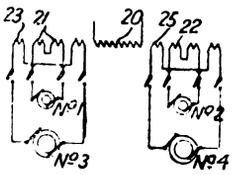

FIG. 2.

on opposite sides of the primaries 3, 4, and the converters are fed from the similar sections 6, 8, and 7, 9. The inductive effect in this case is almost exactly the same when one or both converters are in operation. When three converters are provided the secondary sections for two of them are on opposite sides of the transformer primaries, while those for the third each consist of two parts in series, and located outside of the others. A transformer for each phase is provided. The exact equivalent of the inductive effects with one, two, or three converters in operation is not obtained in this case, but is approximated to. In Fig. 2 will be seen the arrangement of the secondaries, 21, 22, 23, and 25, of each transformer used when four converters, No. 1, No. 2, No. 3, and No. 4, are provided. The compounding effect with one converter, or with one on each side of primaries, 20 in operation in this case, is about half that obtained with all in operation; but with two on the one side of the primaries in operation it is about the same as with all. An effect intermediate between these values is obtained by using any three.

The Past Session.—Compared with last year, there was a falling off in the number of electrical measures before Parliament, the figure for the past session being for traction, lighting, and power, 41, against 58, and of these half a dozen, for one reason or another, failed to become law Traction accounted for 28 Bills, and lighting and power for 13. A portion of the Bills were, as usual, merely for alterations, amendments, or extension of time. In addition, certain corporations promoted omnibus Bills which included electrical matters. On the whole, companies were in a considerable majority over municipalities. The session was somewhat remarkable for the absence of rejected measures, failure to gain the Royal assent being due to abandonment or withdrawal. The promoters of the East London and Lower Thames Power Company did not go beyond depositing their Bill, and the Central London Railway Company withdrew theirs pending the decision of the London Traffic Commission. Few public Acts were before Parliament, and the Supply of Electricity Bill was withdrawn, while a measure entitled "The Tramways and Public Companies (Ireland) Act (1883) Amendment Bill" was abandoned. This withdrawal of the Supply o Electricity Bill for the second time emphasises the laxity which often creeps into our legislative procedure. A mas of evidence was waded through again, and all for nothing the measure being sacrificed through lack of time. The Government really ought to make up its mind to deal with this Bill in a business-like manner. The number of provisional orders granted was little different from last year the figures being 59 for lighting and 12 for tramways against 61 and 13. Under the Scottish Private Legislature Act three orders were granted in reference to tramways. The outstanding feature of the session was the long struggle over the Administrative County of London Power Bill, which, despite the energy of the promoters, failed to gain a place in the Statute-book this session, although ordered for third reading after an extensive inquiry. The London County Council's General Powers Bill excited a lot of discussion in reference to the free-wiring clause, which caused electrical contractors a good deal of alarm. Ultimately, it was decided that the Borough Council should be empowered to borrow money for the purpose of providing free wiring, but that they should not execute the work themselves. The London United Tramways were granted further time for their extensions, which are being proceeded with at a fair pace, and will enable passengers to travel as far as Esher by car. The Metropolitan Electric Supply Company obtained an extension of their area for power supply. A public Bill with an electrical element in it was that of the Pneumatic Tube Despatch Syndicate. The evidence of numerous experts as to its utility failed to convince the committee, who found the preamble non proven. In the latter part of the Session a Select Committee inquired into the agreement entered into by the Postmaster-General with the National Telephone Company for the transfer of the latter's undertaking in 1911. In their report, the Select Committee made recommendations as to the encouragement of municipal systems, but Lord Stanley contended that these were supererogatory, and Parliament upheld that view, so that, in accordance with its terms, the agreement becomes operative automatically at the end of this month.

FROME ELECTRICITY WORKS.

Frome, or to designate it by its more correct name Frome-Selwood—so called because of its ancient proximity to the forest of Selwood—is a prosperous and up-to-date town of about 12,000 inhabitants, situated in the east extremity of Somerset amid picturesque country and

MR. F. HASTINGS MEDHURST, M.I.E.E., CONSULTING ENGINEER.

beautiful and historic surroundings. The annals of the town go far back into the vista of bygone ages; it was known, undoubtedly, to the Romans, and King Alfred's final victory over the Danes was won only a short distance away. The town itself is mentioned in history in the reign of Ina, King of Wessex, when in 689 his near kinsman Aldhelm—a monk of Malmesbury—founded a mission for the purpose of converting the lawless robbers that then infested the surrounding country. Nearly 300 years later, King Edred, "the then most potent King of Britain," was, when at Frome, taken with a grevious sickness in the tenth year of his reign, and died there "ere the blessed Dunstan could reach him to receive his confession." From Doomsday Book we learn that the town then belonged to the King, and occupied the fortunate position of never having been assessed. Thus from century to century the history of Frome could, if space permitted, be traced in considerable detail. The district was loyal to the Stuarts throughout that disastrous period, and the surrounding villages still bear many traces of the stirring events of those times.

Frome ceased to be a borough after the passing of the

MR. F. MICHELL NICHOLL, RESIDENT ENGINEER.

Redistribution of Seats Act, 1884, and the Local Board was, upon the passing of the Local Government Act in 1894, succeeded by the Urban District Council as the local authority for the town. Geography books of early date state Frome to be a town celebrated for cloths and strong beer, but some 20 or 30 years ago the depression in the woollen trade resulted in the closing of several of its largest mills, and for a time it was frequently referred to as "the decaying town of the West." Other industries, however, quickly sprang up, and to-day Frome, for its size, is one of the most flourishing towns in the county. In 1900 the boundaries of the urban district were extended, and immediately after the completion of that undertaking the question of an electrical installation was taken up by

Digitized by Google

the Council. The subject had been discussed on several occasions during the previous autumn, but no definite steps were taken until the spring of 1900. The Council then determined to investigate the matter, and obtained expert advice. Mr. F. H. Medhurst was selected to report on the whole question, and he has continued to act as the Council's consulting engineer to the present time. In his report Mr.

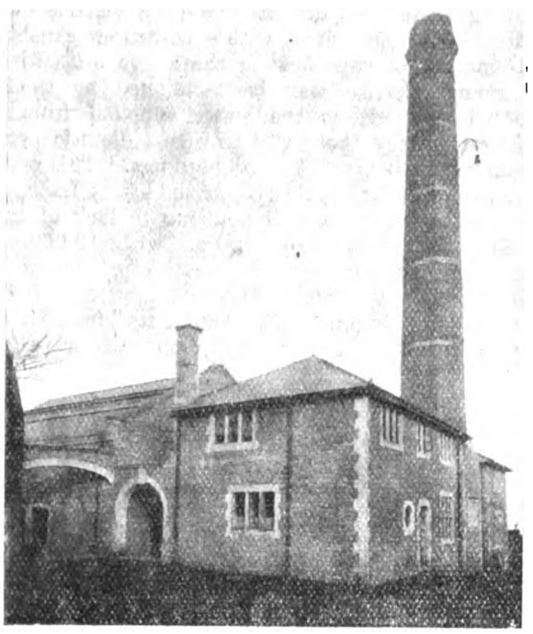

FIG. 1.—Exterior of the Frome Electricity Works.

Medhurst recommended the Council to erect electricity works for continuous-current distribution. An electric lighting order was applied for, and almost immediately it was confirmed a sub-committee was formed to inspect various electricity works. The committee on receipt of their report unanimously recommended the Council to proceed with a scheme of electricity supply, and succeeded

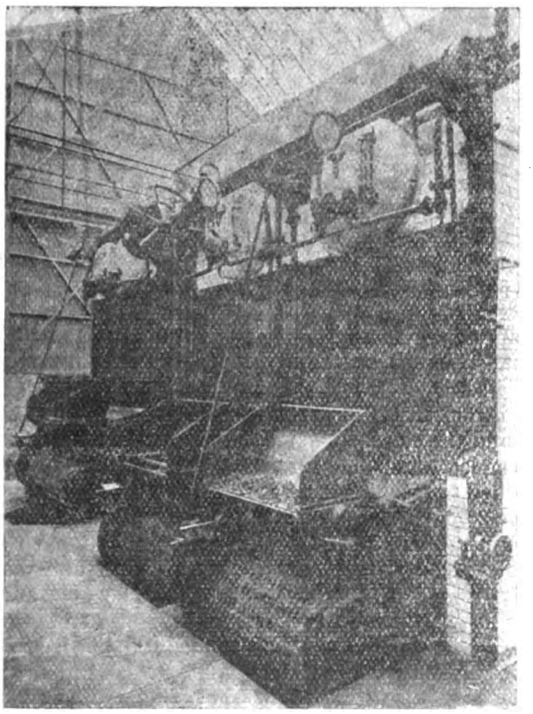

FIG. 2.—The Boiler House, showing Chain Grate Stokers.

in carrying their report. It is interesting to notice that electric lighting matters had been discussed at no less than thirty meetings before the final step was taken. Some months elapsed before further progress was made owing to the opposition of several influential ratepayers, who anticipated that the undertaking would be a burden on the rates, and that a cheaper supply would soon be available from the works which a power company proposed to erect some eight miles away. This company, by the way, has not yet commenced operations. To meet the above objections, Mr. Medhurst suggested that tenders for the complete equipment and maintenance of electricity works should be

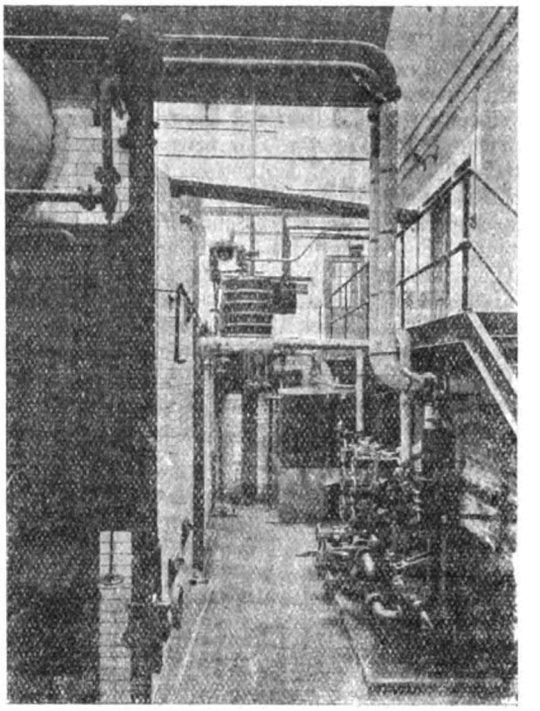

FIG. 3.—Boiler House, showing Pumps and Feed Heater.

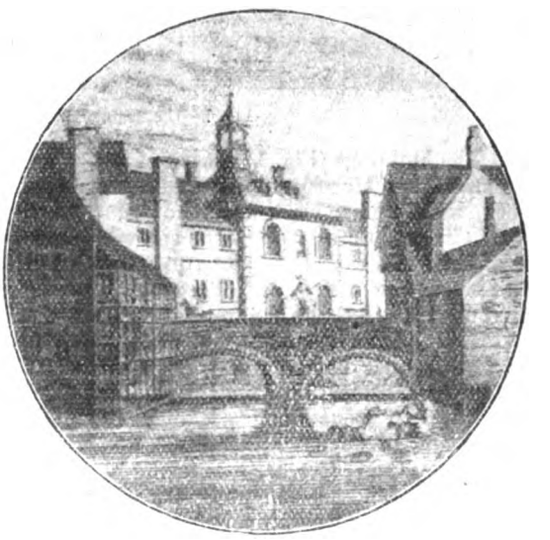
obtained from several firms of undoubted stability, on the basis of the Council raising the necessary capital and paying for the undertaking, the contractors taking, on completion of the scheme, a lease of the undertaking at an annual rental equivalent to the interest and sinking fund on the loan raised by the Council for the equipment of the works; the Council having the right to determine the agreement at the end of 7, 10, or 14 years; the contractors holding their lease for 25 years if so desired, carrying out the works under the supervision of the Council's engineer and maintaining the same to his satisfaction.

Several leading members of the Council, including the chairman, Mr. H. T. Rawlings, and Councillors Seward, Woodland, Penny, and R. T. Rawlings, were strongly in



Frome Town Bridge in 1780.

favour of the scheme being carried out in the ordinary way at the risk of the Council, holding that any initial loss would soon be more than balanced by the success of the undertaking. In deference to the wishes of a number of ratepayers, it was, however, decided in August, 1902, to proceed with a guaranteed scheme as detailed above. Plans and specifications were then prepared by Mr. Medhurst,

Digitized by Google

and the tender of Messrs. Edmundson's Electricity Corporation, Limited, was accepted in January, 1903, the total being £20,156. 5s. Messrs. Edmundson's principal sub-contractors were as follows: buildings and chimney shaft, Messrs. Hodder and Sons, Frome; boilers, mechanical stokers, and steam-pipes, Messrs. Babcock and Wilcox; condensing plant, Messrs. Cole, Marchent, and Morley; water softener, Mr. William Boby; crane, Messrs. Isles; steam-turbine dynamos, Messrs. C. A. Parsons and Co.; balancer booster, Messrs. Thomas Parker; switchboard, Messrs. Edmundson's Electricity Corporation; battery, Messrs. the D.P. Battery Company; mains, Messrs. Callender's Cable and Construction Company; cooling tower, Messrs. the Klein Engineering Company; lamp brackets, Messrs. Singer and Sons, Frome. The Local Government Board inquiry was held in the same month, the sanction of that department obtained in due course, and building operations started in the autumn of 1903.

The works have been erected on a central site acquired by the Council some years previously, formerly occupied by Messrs. E. Cockey and Sons, Limited, the well-known firm of gas engineers, who have long since moved to larger premises. The buildings (Fig. 1) consist of a boiler-house, engine-room, accumulator-room, and chimney shaft, also an office block, with stores, workshop, showroom, engineer's and general offices. Local stone has been used in the construction of the work, with Bath stone quoins and dressings, the whole presenting a neat and pleasing appearance, on which the builders are to be congratulated. The chimney shaft, 110ft. in height from the flue level, and approximately of 6ft. internal diameter, rests upon a bed of concrete on solid rock, some 15ft. from the surface. The base, of stone, with bath stone quoins, is 30ft. in height, the shaft itself being of octagonal section. Red Cattybrook bricks have been used here, with relieving bands of white brick. The cornice and cap of blue Staffordshire brick give a satisfactory finish to a well-proportioned shaft. Entrance to the offices is obtained on the east side of the building, a staircase leading from the hall to the engineer's office, general office, and showroom on the first floor. The stores and lavatory are situated on either side of a passage leading from the hall to the workshop. Access is given here to a small yard, and this forms an additional entrance to the works. A second door in the workshop opens on to a gallery in the boiler-house. This section of the works is 48ft. in length, 42ft. in width, and 26ft. in height to the springing of the roof. The coal bunkers in communication with it have been built below the ground level for convenience in handling the coal. The storage capacity of the bunkers is about 80 tons.

The steam raising plant (Fig. 2) consists of three water-tube boilers of Babcock and Wilcox's manufacture, two to evaporate 5,000lb. of water per hour and one 7,000lb. per hour at a working pressure of 160lb. per square inch. These boilers are fitted with chain-grate mechanical stokers. The moving grates are driven by a 4-h.p. electric motor. The boilers have been fitted with superheaters capable of giving 150deg. F. of superheat to the above quantities of steam. Some surprise may be occasioned by the use of water-tube boilers, as the water supplied from the Council's waterworks, though of excellent dietetic properties, contains some 25deg. of total hardness. This matter, however, was carefully considered, as the use of Lancashire boilers was out of the question owing to lack of space. Condensing plant capable of dealing with 10,000lb. of steam per hour has been provided for the turbines, so that condensed steam is available for feeding the boilers. A 28in. vacuum is usually obtained. The "make up" feed water is softened by a Boby-Chevalet heater detartariser (Fig. 3). In this apparatus unsoftened water is admitted at the top and exhaust steam at the bottom, the steam passing up through a series of trays boils the water. The carbonate of lime is deposited in the trays and settling tank at the bottom, and the softened water is then ready for use.

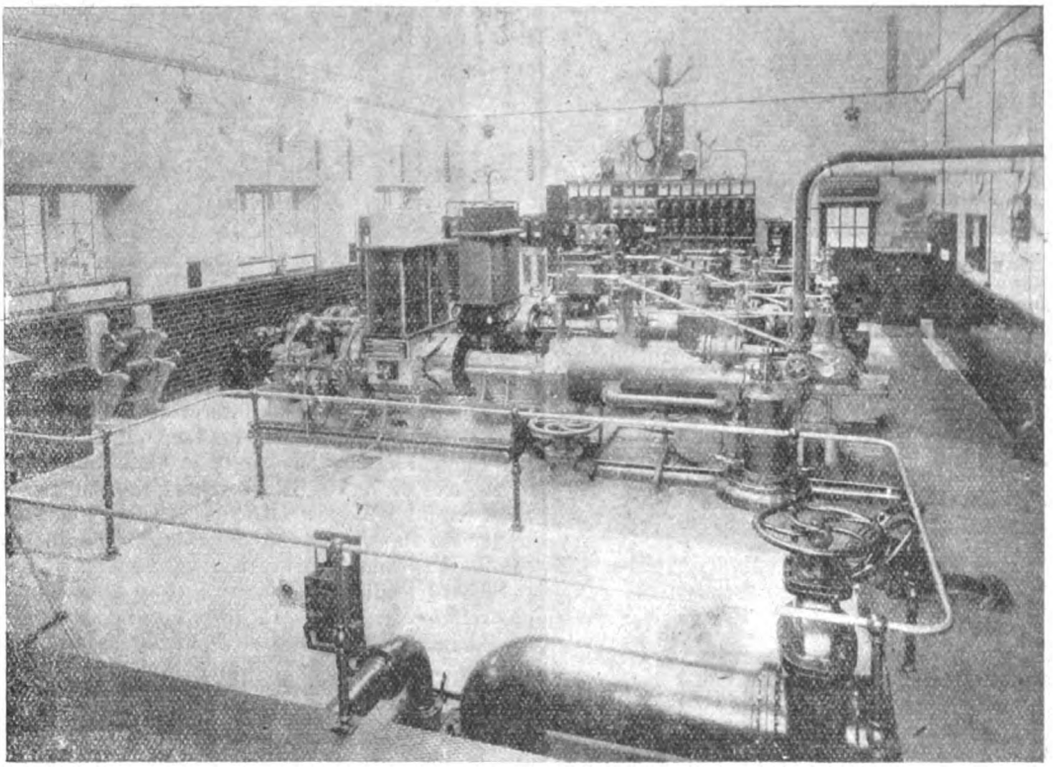


FIG. 4.—The Engine Room at Frome, showing the Parsons Turbo-Generator.

Two vertical compound direct-acting Hall steam pumps are provided for feeding the boilers. Each pump is designed to deliver 2,000 gallons of water per hour against a pressure of 160lb. per square inch. Each boiler can be supplied with either hot or cold water. The steam pipes are of wrought steel, with valves of Dewrance's make. The whole system of piping has been carefully arranged, all water from drains is collected and utilised, and the steam and hot-feed pipes and valves lagged with mica coverings.

A door at the north end of the gallery in the boiler-house gives access to the engine-room. This is 48ft. in length, 30ft. in width, and 18ft. in height to the springing of the roof. A five-ton overhead travelling crane spans the building, which, with its terazzo floor, glazed tile dado, polished metal work, and general neatness reflects credit on its designers. It is, without doubt, one of the daintiest, and at the same time one of the most business-like engine-rooms to be found in or out of the West Country.

The electrical equipment (Fig. 4) comprises three Parsons

Digitized by Google

steam-turbine dynamos, running at 3,650 r.p.m., and the usual accessories. Two of these turbines are 150-kw. machines, or 250 h.p. each, and one is a 75-kw. machine. This type of plant runs practically without vibration, and was adopted in consequence of the bad foundations.

FROME TURBO-GENERATORS.—TEST AT MAKERS' WORKS.

Load.	Kilo-watts	R.P.M.	Steam pressure at stop valve of turbine. Lbs per square inch.	Super-heat Deg. F.	Vacuum. Inches of mercury.	Llbs. steam per kilowatt-hour.
Full...	150	3,650	143	134	24 9	24·3
Half...	150	3,650	156	123	24·7	31·3
Full...	75	4,300	147	145	24	27·6
Half...	75	4,300	147	151	24	37·7

Details of the tests made on these sets are given in the table. They govern within 2 per cent. from full load to no-load, and can give 10 per cent. overload when running non-condensing. The exhaust steam from the turbines is led to a surface condenser sunk in a pit in the engine-room. The condenser is supplied with water from a Klein's cooling-tower erected at the west end of the site. The tower, of creosoted timber, is built over a concrete tank 10ft. in depth, and is 40ft. in length, 32ft. wide, and 65ft. high. The circulating water (40,000 gallons per hour at full load) flows from the tank under the tower, passes through the condenser, and is forced to a point in the tower some 30ft. from the ground. It is thence distributed in small quantities over a number of laths down which it trickles to the tank below and again flows to the condenser. The temperature of the water is, of course, lowered by its partial evaporation in contact with the draught of air created in the tower, which is open to the atmosphere at its base and acts in the same way as a ventilating shaft. The condenser is provided with an Edwards three-throw air-pump and with a centrifugal circulating pump driven by a 20-b.h.p. electric motor.

The current generated by the steam-turbine dynamos at from 480 to 530 volts is taken to the main switchboard, and from thence it flows through the various measuring and regulating instruments to the feeding and distributing mains. Separate mains are run to various parts of the town, so that in the event of a cable breaking down only a small part of the town would be affected. The cables are of the well-known Callender type, lead covered and further protected by steel tapes wound on spirally. They are laid direct in the ground and covered with hard bricks. All the connections between feeders and distributing cables are made in feeder pillars of the Callender-Ward type. The feeders are triple-concentric cables, and for the distributors three and four core cables are used. The latter four-core cables are used where street-lighting has to be supplied from the private-lighting mains.

On the north side of the engine-room is the "balancer booster" for balancing the three-wire system, and for charging the batteries. The balancer can deal with 60 amperes out-of-balance current on the 240-480 volt system. The boosters can each add 85 volts when passing a current of 54 amperes to the batteries. The accumulators consist of 260 D.P. cells, with a capacity of 400 ampere-hours. They have been placed in a spacious room at the back of the switchboard.

The growth of the undertaking has been very rapid and points to a successful working from a commercial point of view. The number of applications for light and power early necessitated the substitution of a 150-kw. turbo-generator, in the place of the second 75 kw. originally specified, and a third generator set and boiler have already been added.

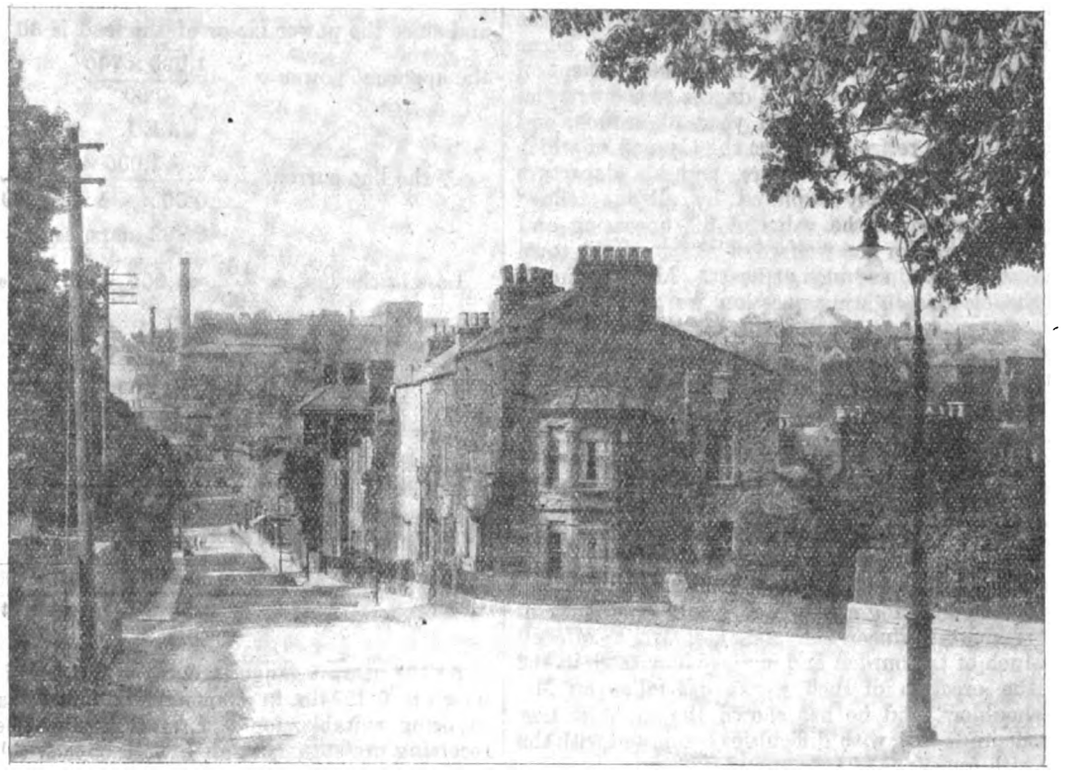

FIG. 5.—View from North-parade, Frome, showing Electric Lamp for Street Lighting.

A supply of current was first given to private consumers on July 1, 1904, and the streets were lit by electricity for the first time on Aug. 1, 1904. The original intention of the Council was to erect 10 arc lamps and about 41 incandescent lamps in the streets. The contractors, however, submitted a tender for the whole of the street-lighting on favourable terms, and the streets are now lighted by 10 three-ampere twin-carbon arc lamps of the Reason type, and 261 incandescent Nernst lamps of 80 c.p. The lamps are switched off at 11.30 p.m., with the exception of two 40-c.p. lamps on the arc lamp posts, which are switched on automatically when the arcs are switched off, and 46 of the Nernst lamps at street corners. New posts have been ordered for additional lamps, but the majority of the gas lamp posts have been utilised, fitted with graceful brackets, manufactured at Messrs. Singer's Art Metal Works. The lamps are controlled in groups from switch pillars, and the general effect of the lighting is considered highly satisfactory.

The contractors have adopted a spirited policy in the matter of charges for electrical energy. The price per unit on the maximum demand system is 7d. and 4d. per unit for lighting and power respectively for any quantity up to the amount which would have been used if the maximum

Digitized by Google

demand had continued for approximately one hour each day per quarter, and for any further units 3d. for lighting and 1d. for power, or a flat rate of 6d. for lighting and 2½d. for power. The price of gas in the town, it may be noted, was 3s. 4d. per 1,000 cubic feet until the works were under construction, since when it has been 3s. per 1,000 cubic feet. The contractors wire houses complete, if so desired, and charge a rental for the use of the installation of 4½d. per lamp per quarter. Alternatively, the installation can be paid for by instalments, spread over a number of years. In special cases current is supplied by 1d. or 1s. in the slot meters, at 7d. per unit. This charge covers both the rent of the meter and the rent of the installation. Motors and other apparatus can also be hired, and several of the leading manufacturers of the town have given a considerable impetus to the undertaking by substituting electric motors for their existing steam or gas engines. The number of motors on the mains is now 102, the range being from 35 h.p. to ¼ h.p. The equivalent number of 8-c.p. lamps, including all current-consuming apparatus, at the commencement of supply was 3,050 and at the present time is 19,579, while a further number of over 1,500 8-c.p. lamps await connection.

No description of the Frome Electricity Works would be complete without some acknowledgment of the valuable services of Mr. H. T. Rawlings, the chairman of the Council from 1898 to 1904, and others who have borne "the burden and heat of the day." The establishment of the undertaking was due in no small degree to the energies of Mr. Rawlings, spread over several years of arduous and incessant work. His retirement from the Council, of which he had been a member for 12 years, and his departure from Frome, are genuinely deplored by all his fellow-townsmen, who appreciate the value of his unceasing and unostentatious efforts for the welfare of the good old town whose interests he had so much at heart. Mr. Rawlings's views on the electric lighting question were shared, and vigorously advanced, by a number of his colleagues, who have every reason to look back upon their labours with feelings of satisfaction. The services of the popular clerk to the Council, Mr. Ames, in the cause of electricity have proved of the highest value. His keen interest in the scheme has been a leading factor in its success. Mr. George T. Pardoe has acted as clerk of works, and has ably supported the Council's interests.

Messrs. Edmundson's Electricity Corporation have carried out the contract in their usual thorough and workmanlike manner, and no little credit for the success of the installation is due to the untiring energy and wide experience of their able resident engineer and manager, Mr. F. Michell Nicholl. Much of the burden and anxiety inevitable in the course of the erection of such works has fallen on Mr. Nicholls's shoulders, and he has shown the greatest tact and judgment in dealing with difficulties connected with the works and with questions of supply and demand.

In a word, no effort has been spared to provide up-to-date and efficient electricity works, and an inspection shows that the consulting engineers, Messrs. F. H. Medhurst and Lloyd, are to be congratulated on the result. Most of the photographs from which the above illustrations were made were taken by Mr. W. F. Wheeler, of Frome.

NOTES ON AERIAL POWER LINES.

(Continued from page 192.)

BY CHE.

Before applying the particulars already given respecting the mechanics of the problem it will be well to point out that the existence of tension implies elastic stretching, and that elastic extension is a factor which has not received sufficient attention in the past. If we suppose, for instance, that the tension of the wire becomes F_1, instead of F, the length of the wire becomes

$$L_1 = l\left(1+\frac{l^2 w_1^2}{24 F_1^2}\right) \quad . \quad . \quad . \quad (4a)$$

and if the temperature falls at the same time to the temperature θ_1 C, the length of the wire will be given by the formula

$$L_1 = L\{1+\alpha(\theta_1-\theta)+\epsilon(F_1-F)\} \quad . \quad . \quad (11)$$

in which ϵ = coefficient of elasticity of the material of the wire. From equations (4) and (4a) and by substitution we have

$$l\left(1+\frac{l^2 w_1^2}{24 F_1^2}\right) = l\left(1+\frac{l^2 w^2}{24 F^2}\right)\{1+\alpha(\theta_1-\theta)+\epsilon(F_1-F)\}$$

which gives (by neglecting products containing terms above the first degree) the approximate relation

$$\frac{l^2 w_1^2}{24 F_1^2} - \left[\alpha(\theta_1-\theta)+\epsilon F_1\right] = \frac{l^2 w^2}{24 F^2} - \epsilon F \quad . \quad (12)$$

A knowledge of the most unfavourable conditions—i.e., a knowledge of α, θ_1, θ, w, w_1 and F_1—enables the best length to be determined to give to the span and to the tension, F, for normal working conditions.

Let us now consider the following problem: *It is required to transmit 1,000 h.p. a distance of 50 miles by means of three-phase currents at a frequency of 50 periods, the pressure between the line wires at the receiving end being 20,000 volts. The power factor of the load may be taken as 80 per cent., and the power lost in the line should not exceed 15 per cent. of that received.*

Let E = pressure between the line wires, and I = line current.

then power received $= \sqrt{3}\,E\,I\cos\theta$;

and since the power factor of the load is 80 per cent.,

$$\text{the apparent power} = \frac{1{,}000\times 746}{0{\cdot}80}$$

$$= \sqrt{3}\,E\,I.$$

$$\therefore \text{ the line current } I = \frac{1{,}000\times 746}{0{\cdot}80\times\sqrt{3}\times 20{,}000}$$

$$= 26{\cdot}92 \text{ amperes.}$$

$$\text{Loss in the line} = \frac{15}{100}\times 1{,}000\times 746 \text{ watts}$$

$$= 3\,I^2\,R,$$

if R = resistance of each line wire.

$$\therefore \quad R = \frac{150\times 746}{3\times(26{\cdot}92)^2} \text{ ohms.}$$

but $$R = \frac{{\cdot}66}{10^6}\times\frac{50\times 5{,}280\times 12}{{\cdot}7854 d^2};$$

where d = diameter of the wire in inches.

$$\therefore\ d = \sqrt{\frac{{\cdot}66\times 50\times 5{,}280\times 12\times(26{\cdot}92)^2}{10^6\times{\cdot}7854\times 50\times 746}}$$

$$= 0.232\text{in.}$$

As the nearest gauge (B.& S.) to this size of wire is No. 3, which is 0·2294in. in diameter, this wire may be selected as being suitable for the transmission line. Since the receiving pressure is high it will be advisable to dispose the three-line wires at the corners of an equilateral triangle of 5ft. 2in. (62in.) side; and electrically it is important to determine the drop in volts in the line and the voltage at the beginning of the line. The resistance of a wire 0·2294in. in diameter and 50 miles in length is

$$R = \frac{{\cdot}66}{10^6}\times\frac{50\times 5{,}280\times 12}{{\cdot}7854\times({\cdot}2294)^2}$$

$$= 50{\cdot}6 \text{ ohms.}$$

Therefore, the drop in volts in each line is $e_p = R\,I$, or

$$e_p = 50{\cdot}6\times 26{\cdot}92 \text{ volts}$$

$$= 1{,}362{\cdot}15 \text{ volts.}$$

The next important factor is the reactance drop in the line, and this is

$$e_s = 2\pi \sim L\,I,$$

in which L is the inductance of two wires 62in. apart and 50 miles long, and which may be obtained by Maxwell's formula,

$$L = 2\,l\left[0{\cdot}5+2\log_\epsilon\frac{d_1}{r}\right]\times\frac{1}{10^9} \text{ henrys,}$$

in which L = the coefficient of self-induction of two long, straight, and parallel copper wires, l the transmission length in centimetres, d_1 the distance between the centres of the wires, and r is the radius of the wire. For practical pur-

Digitized by Google

poses it is more convenient to work with the distance in feet, and if l' denotes the transmission length in feet, the above formula becomes

$$L = 2\,l'\,(2{\cdot}54 \times 12)\left[{\cdot}5 + 2 \times 2{\cdot}3026 \log \frac{d_1}{r}\right] \times \frac{1}{10^9} \text{ henrys.}$$

$$= 2\,l'\left[15{\cdot}24 + 140{\cdot}366 \log \frac{d_1}{r}\right] 10^{-9} \text{ henrys.}$$

$$\therefore L = 2 \times 50 \times 5{,}280\left[15{\cdot}24 + 140{\cdot}366 \log \frac{62}{{\cdot}1147}\right] 10^{-9} \text{ henrys}$$

and $$\log \frac{62}{{\cdot}1147} = \log 540 = 2{\cdot}732.$$

$$\therefore L = 528\,[15{\cdot}24 + 140{\cdot}366 \times 2{\cdot}732]\,10^{-6} \text{ henrys}$$

$$= 0{\cdot}2105416 \text{ henry,}$$

and the reactance $= 2\,\pi \sim L$

$$= 2 \times 3{\cdot}1416 \times 50 \times 0{\cdot}2105416$$

$$= 66{\cdot}13 \text{ ohms.}$$

$$\therefore \text{reactance drop} = e_s = 66{\cdot}13 \times 26{\cdot}92$$

$$= 1{,}780 \text{ volts.}$$

The vector diagram showing the phase-relationships existing between the generator E.M.F., O E, the receiver pressure, O E_1, the resistance drop, $E_1 E_2$ (e_p), and reactance drop, (e_s) E_2 E, are shown in Fig. 3. The

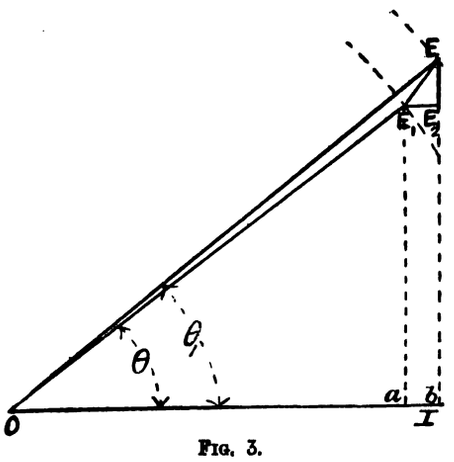

FIG. 3.

actual line drop is given by the arithmetical difference between O E and O E_1 (and not by the vector E_1 E) as indicated by the dotted arcs of the circles. The phase of the current is given by the vector O I, and since the power factor of the load is cos $\theta = 0{\cdot}8$

$$O\,a = O\,E_1 \times \cos\theta$$

$$= 20{,}000 \times 0{\cdot}8 = 16{,}000$$

and $$a\,E_1 = 12{,}000 = E_2\,b$$

$$\therefore O\,E = \sqrt{(O\,b)^2 + (b\,E)^2}$$

$$= \sqrt{(16{,}000 + 1{,}362)^2 + (12{,}000 + 1{,}780)^2}$$

$$= 22{,}166 \text{ volts,}$$

and the drop in the line is O E − O E_1, or 22,166 − 20,000 = 2,166 volts, and this is 10·83 per cent of the receiver pressure.

It may be noted that $E_1\,E = \sqrt{e_p^2 + e_s^2}$

$$= \sqrt{(1{,}362)^2 + (1{,}780)^2}$$

$$= 2{,}241 \text{ volts.}$$

From Fig. 3 it is obvious that in this case the inductance of the line has but a slight effect upon the phase relation between the current and the pressure—*i.e.*, $(\theta_1 - \theta)$ is a small angle. As regards the efficiency of the line we have

$$\eta = \frac{P}{P + 3\,I^2R};$$

in which P = power delivered, and I^2R = watts lost in the line, therefore

$$\eta = \frac{1{,}000}{1{,}000 + \dfrac{3\,(26{\cdot}92)^2 \times 50{\cdot}6}{746}};$$

$$= \frac{1{,}000}{1{,}147{\cdot}45} = 87{\cdot}1 \text{ per cent.}$$

(To be continued.)

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The South African tour of this association was inaugurated at Cape Town on Tuesday last when the President, Prof G. H. Darwin, M.A., LL.D., Ph.D., F.R.S., delivered the first portion of his address. The second portion is being reserved till the members meet in Johannesburg.

Professor Darwin in the commencement of his address said: Bartholomeu Diaz, the discoverer of the Cape of Storms, spent sixteen months on his voyage, and the little fiotilla of Vasco da Gama, sailing from Lisbon on July 8, 1497, only reached the Cape in the middle of November. These bold men, sailing in their puny fishing smacks to unknown lands, met the perils of the sea and the attacks of savages with equal courage. How great was the danger of such a voyage may be gathered from the fact that less than half the men who sailed with da Gama lived to return to Lisbon. Four hundred and eight years have passed since that voyage, and a ship of 13,000 tons has just brought us here, in safety and luxury, in but little more than a fortnight.

How striking are the contrasts presented by these events! On the one hand compare the courage, the endurance, and the persistence of the early navigators with the little that has been demanded of us; on the other hand consider how much man's power over the forces of Nature has been augmented during the past four centuries. The capacity for heroism is probably undiminished, but certainly the occasions are now rarer when it is demanded of us. If we are heroes, at least but few of us ever find it out, and, when we read stories of ancient feats of courage, it is hard to prevent an uneasy thought that, notwithstanding our boasted mechanical inventions, we are perhaps degenerate descendants of our great predecessors.

Yet the thought that to-day is less romantic and less heroic than yesterday has its consolation, for it means that the lot of man is easier than it was. Mankind, indeed, may be justly proud that this improvement has been due to the successive efforts of each generation to add to the heritage of knowledge handed down to it by its predecessors, whereby we have been born to the accumulated endowment of centuries of genius and labour.

I am told that in the United States the phrase "I want to know" has lost the simple meaning implied by the words, and has become a mere exclamation of surprise. Such a conventional expression could hardly have gained currency except amongst a people who aspire to knowledge. The dominance of the European race in America, Australasia, and South Africa has no doubt arisen from many causes, but amongst these perhaps the chief one is that not only do "we want to know," but also that we are determined to find out. And now, within the last quarter of a century, we have welcomed into the ranks of those who "want to know" an Oriental race, which has already proved itself strong in the peaceful arts of knowledge.

I take it, then, that you have invited us because you want to know what is worth knowing; and we are here because we want to know you, to learn what you have to tell us, and to see that South Africa of which we have heard so much.

The hospitality which you are offering us is so lavish, and the journeys which you have organised are so extensive, that the cynical observer might be tempted to describe our meeting as the largest picnic on record. Although we intend to enjoy our picnic with all our hearts, yet I should like to tell the cynic, if he is here, that perhaps the most important object of these conferences is the opportunity they afford for personal intercourse between men of like minds who live at the remotest corners of the earth.

We do not know whether the last hundred years will be regarded for ever as the *sæculum mirabile* of discovery, or whether it is but the prelude to yet more marvellous centuries. To us living men, who scarcely pass a year of our lives without witnessing some new marvel of discovery or invention, the rate at which the development of knowledge proceeds is truly astonishing; but from a wider point of view the scale of time is relatively unimportant, for the universe is leisurely in its procedure. Whether the changes

Digitized by Google

which we witness be fast or slow, they form a part of a long sequence of events which begin in some past of immeasurable remoteness, and tend to some end which we cannot foresee. It must always be profoundly interesting to the mind of man to trace successive cause and effect in the chain of events which make up the history of the earth and all that lives on it, and to speculate on the origin and future fate of animals, and of planets, suns, and stars. I shall try, then, to set forth in my address some of the attempts which have been made to formulate evolutionary speculation. This choice of a subject has, moreover, been almost forced on me by the scope of my own scientific work, and it is, I think, justified by the name which I bear. It will be my fault and your misfortune if I fail to convey to you some part of the interest which is naturally inherent in such researches.

Prof. Darwin then dealt with several branches of his subject, which are outside the scope of our paper. He afterwards said: Evolutionary doctrines concerning inanimate Nature, although of much older date than those which concern life, have been profoundly affected by the great impulse of which I have spoken. It has thus come about that the origin and history of the chemical elements and of stellar systems now occupy a far larger space in the scientific mind than was formerly the case. The subject which I shall discuss to-night is the extent to which ideas, parallel to those which have done so much towards elucidating the problems of life, hold good also in the world of matter; and I believe that it will be possible to show that in this respect there exists a resemblance between the two realms of Nature, which is not merely fanciful. It is proper to add that as long ago as 1873 Baron Karl du Prel discussed the same subject from a similar point of view, in a book entitled "The Struggle for Life in the Heavens."

Although inanimate matter moves under the action of forces which are incomparably simpler than those governing living beings, yet the problems of the physicist and the astronomer are scarcely less complex than those which present themselves to the biologist. The mystery of life remains as impenetrable as ever, and in his evolutionary speculations the biologist does not attempt to explain life itself, but, adopting as his unit the animal as a whole, discusses its relationships to other animals and to the surrounding conditions. The physicist, on the other hand, is irresistibly impelled to form theories as to the intimate constitution of the ultimate parts of matter, and he desires further to piece together the past histories and the future fates of planets, stars, and nebulæ. If then the speculations of the physicist seem in some respects less advanced than those of the biologist, it is chiefly because he is more ambitious in his aims. Physicists and astronomers have not yet found their Johannesburg or Kimberley; but, although we are still mere prospectors, I am proposing to show you some of the dust and diamonds which we have already extracted from our surface mines.

The fascinating idea that matter of all kinds has a common substratum is of remote antiquity. In the Middle Ages the alchemists, inspired by this idea, conceived the possibility of transforming the baser metals into gold. The sole difficulty seemed to them the discovery of an appropriate series of chemical operations. We now know that they were always indefinitely far from the goal of their search, yet we must accord to them the honour of having been the pioneers of modern chemistry.

The object of alchemy, as stated in modern language, was to break up or dissociate the atoms of one chemical element into its component parts, and afterwards to reunite them into atoms of gold. Although even the dissociative stage of the alchemist problem still lies far beyond the power of the chemist, yet modern researches seem to furnish a sufficiently clear idea of the structure of atoms to enable us to see what would have to be done to effect a transformation of elements. Indeed, in the complex changes which are found to occur spontaneously in uranium, radium, and the allied metals we are probably watching a spontaneous dissociation and transmutation of elements.

Natural selection may seem, at first sight, as remote as the poles asunder from the ideas of the alchemist, yet dissociation and transmutation depend on the instability and regained stability of the atom, and the survival of the stable atom depends on the principle of natural selection.

Until some 10 years ago the essential diversity of the chemical element was accepted by the chemist as an ultimate fact, and, indeed, the very name of atom, or that which cannot be cut, was given to what was supposed to be the final indivisible portion of matter. The chemist thus proceeded in much the same way as the biologist, who, in discussing evolution, accepts the species as his working unit. Accordingly, until recently the chemist discussed working models of matter of atomic structure, and the vast edifice of modern chemistry has been built with atomic bricks.

But within the last few years the electrical researches of Lenard, Röntgen, Becquerel, the Curies, of my colleagues Larmor and Thomson, and of a host of others, have shown that the atom is not indivisible, and a flood of light has been thrown thereby on the ultimate constitution of matter. Amongst all these fertile investigators it seems to me that Thomson stands pre-eminent, because it is principally through him that we are to-day in a better position for picturing the structure of an atom than was ever the case before.

Even if I had the knowledge requisite for a complete exposition of these investigations, the limits of time would compel me to confine myself to those parts of the subject which bear on the constitution and origin of the elements.

It has been shown, then, that the atom, previously supposed to be indivisible, really consists of a large number of component parts. By various convergent lines of experiment it has been proved that the simplest of all atoms—namely, that of hydrogen—consists of about 800 separate parts, while the number of parts in the atom of the denser metals must be counted by tens of thousands. These separate parts of the atom have been called corpuscles or electrons, and may be described as particles of negative electricity. It is paradoxical, yet true, that the physicist knows more about these ultra-atomic corpuscles, and can more easily count them than is the case with the atoms of which they form the parts.

The corpuscles, being negatively electrified, repel one another just as the hairs on a person's head mutually repel one another when combed with a vulcanite comb. The mechanism is as yet obscure whereby the mutual repulsion of the negative corpuscles is restrained from breaking up the atom, but a positive electrical charge, or something equivalent thereto, must exist in the atom so as to prevent disruption. The existence in the atom of this community of negative corpuscles is certain, and we know further that they are moving with speeds which may in some cases be comparable to the velocity of light—namely, 200,000 miles a second. But the mechanism whereby they are held together in a group is hypothetical.

It is only just a year ago that Thomson suggested, as representing the atom, a mechanical or electrical model whose properties could be accurately examined by mathematical methods. He would be the first to admit that his model is at most merely a crude representation of actuality, yet he has been able to show that such an atom must possess mechanical and electrical properties which simulate, with what Whetham describes as "almost Satanic exactness," some of the most obscure and yet most fundamental properities of the chemical elements. "Se non è vero, è ben trovato," and we are surely justified in believing that we have the clue which the alchemists sought in vain.

Thomson's atom consists of a globe charged with positive electricity, inside which there are some thousand or thousands of corpuscles of negative electricity, revolving in regular orbits with great velocities. Since two electrical charges repel one another if they are of the same kind, and attract one another if they are of opposite kinds, the corpuscles mutually repel one another, but all are attracted by the globe containing them. The forces called into play by these electrical interactions are clearly very complicated, and you will not be surprised to learn that Thomson found himself compelled to limit his detailed examination of the model atom to one containing about 70 corpuscles. It is indeed a triumph of mathematical power to have determined the mechanical conditions of such a miniature planetary system as I have described.

Digitized by Google

It appears that there are definite arrangements of the orbits in which the corpuscles must revolve, if they are to be persistent or stable in their motions. For the purpose of general discussion, which is all that I shall attempt, you may take it that the number of corpuscles in such a community is fixed; and we may state that definite numbers of corpuscles are capable of association in stable communities of definite types.

An infinite number of communities are possible, possessing greater or lesser degress of stability. Thus the corpuscles in one such community might make thousands of revolutions in their orbits before instability declared itself; such an atom might perhaps last for a long time as estimated in millionths of seconds, but it must finally break up and the corpuscles must disperse or rearrange themselves after the ejection of some of their number. We are thus led to conjecture that the several chemical elements represent those different kinds of communities of corpuscles which have proved by their stability to be successful in the struggle for life. If this is so, it is almost impossible to believe that the successful species have existed for all time, and we must hold that they originated under conditions about which I must forbear to follow Sir Norman Lockyer in speculating.

But if the elements were not eternal in the past, we must ask whether there is reason to believe that they will be eternal in the future. Now, although the conception of the decay of an element and its spontaneous transmutation into another element would have seemed absolutely repugnant to the chemist until recently, yet analogy with other moving systems seems to suggest that the elements are not eternal.

At any rate it is of interest to pursue to its end the history of the model atom which has proved to be so successful in imitating the properties of matter. The laws which govern electricity in motion indicate that such an atom must be radiating or losing energy, and, therefore, a time must come when it will run down, as a clock does. When this time comes it will spontaneously transmute itself into an element which needs less energy than was required in the former state. Thomson conceives that an atom might be constructed after his model so that its decay should be very slow. It might, he thinks, be made to run for a million years, but it would not be eternal.

Such a conclusion is an absolute contradiction to all that was known of the elements until recently, for no symptoms of decay are perceived, and the elements existing in the solar system must already have lasted for millions of years. Nevertheless, there is good reason to believe that in radium, and in other elements possessing very complex atoms, we do actually observe that break-up and spontaneous rearrangement which constitute a transmutation of elements.

It is impossible as yet to say how science will solve this difficulty, but future discovery in this field must surely prove deeply interesting. It may well be that the train of thought which I have sketched will ultimately profoundly affect the material side of human life, however remote it may now seem from our experience of daily life.

I have not as yet made any attempt to represent the excessive minuteness of the corpuscles, of whose existence we are now so confident; but, as an introduction to what I have to speak of next, it is necessary to do so. To obtain any adequate conception of their size we must betake ourselves to a scheme of threefold magnification. Lord Kelvin has shown that, if a drop of water were magnified to the size of the earth the molecules of water would be of a size intermediate between that of a cricket ball and of a marble. Now each molecule contains three atoms, two being of hydrogen and one of oxygen. The molecular system probably presents some sort of analogy with that of a triple star; the three atoms, replacing the stars, revolving about one another in some sort of dance which cannot be exactly described. I doubt whether it is possible to say how large a part of the space occupied by the whole molecule is occupied by the atoms; but perhaps the atoms bear to the molecule some such relationship as the molecule to the drop of water referred to. Finally, the corpuscles may stand to the atom in a similar scale of magnitude. Accordingly a threefold magnification would be needed to bring these ultimate parts of the atom within the range of our ordinary scales of measurement.

I have already considered what would be observed under the triply powerful microscope, and must now return to the intermediate stage of magnification, in which we consider those communities of atoms which form molecules. This is the field of research of the chemist. Although prudence would tell me that it would be wiser not to speak of a subject of which I know so little, yet I cannot refrain from saying a few words.

The community of atoms in water has been compared with a triple star, but there are others known to the chemist in which the atoms are to be counted by fifties and hundreds, so that they resemble constellations.

I conceive that here again we meet with conditions similar to those which we have supposed to exist in the atom. Communities of atoms are called chemical combinations, and we know that they possess every degree of stability. The existence of some is so precarious that the chemist in his laboratory can barely retain them for a moment; others are so stubborn that he can barely break them up. In this case, dissociation and reunion into new forms of communities are in incessant and spontaneous progress throughout the world. The more persistent or more stable combinations succeed in their struggle for life, and are found in vast quantities, as in the cases of common salt and of the combinations of silicon. But no one has ever found a mine of gun-cotton, because it has so slight a power of resistance. If, through some accidental collocation of elements, a single molecule of gun-cotton were formed, it would have but a short life.

Stability is, further, a property of relationship to surrounding conditions; it denotes adaptation to environment. Thus salt is adapted to the struggle for existence on the earth, but it cannot withstand the severer conditions which exist in the sun.

[The President here announced that he proposed to consider various theories of evolution in the heavens in the second portion of his address, to be delivered at Johannesburg on Wednesday, Aug. 30.]

HOTEL WIRING.

It is the fashion on the Continent much more than here to arrange electric incandescent lamps so that they may be controlled from more than one position. In this country we have hitherto limited the application of the principle mainly to corridor and hall lighting. To be able to switch

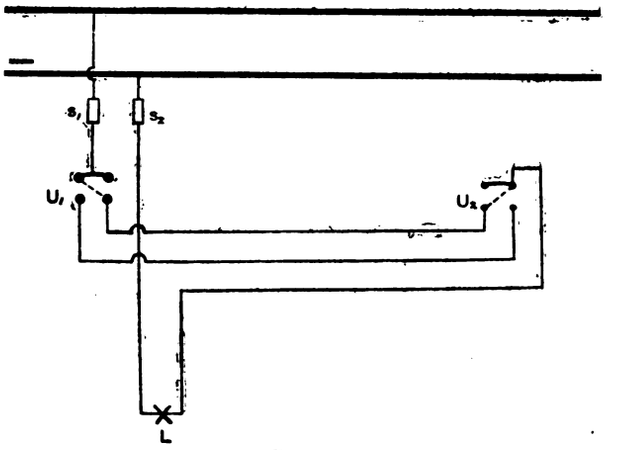

FIG. 1.

on a light from either end of a corridor has been recognised as a convenience and adopted, while the same applies in the case of a hall or landing light, which can be controlled from both the foot and head of the staircase. Continental engineers have, however, given the system wider application. In a German hotel, for instance, it is not unusual to find that one's bedroom lamp or lamps can be controlled from two different points. Complications are necessarily involved, but convenience is held to be of primary importance in these matters. In a contribution to the *Elektrotechnischer Anzeiger* "A. H." describes some current

Digitized by Google

practice. The diagram (Fig. 1) represents a common arrangement of connections. In this example the lamp, L, is supposed to be fixed in a central position for general illumination, while one single-pole two-way switch, U_1, is placed near the door and another, U_2, within convenient reach of the bed. The lamp, it will be seen, may be controlled from either switch at will. The switches themselves are preferably of the quick make-and-break two-way type. The only complication, and possible extravagance where the local conditions are unfavourable, is the necessity for three connections to each switch. When surface wiring on porcelain insulators with treble flexible is used it looks ugly, and with conduit wiring it is frequently found

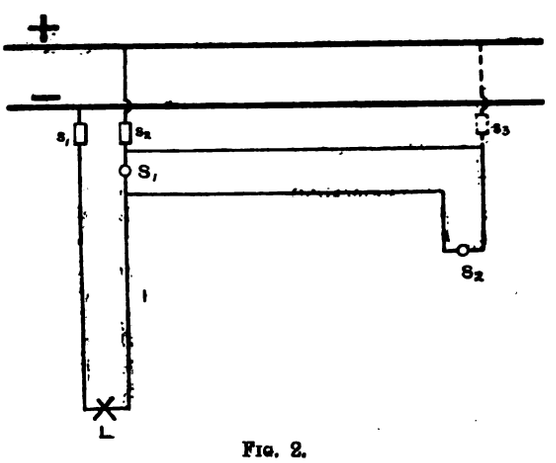

Fig. 2.

necessary to lay two tubes, apart from any preference which may be given to separate wires on account of greater safety. Reverting to the diagram, it should be mentioned that s_1 and s_2 represent fuses. Should it suffice to control the lamp from different points by means of two switches, S_1 and S_2, arranged in parallel as shown in Fig. 2, the connections are considerably modified, two wires only, frequently, indeed, but one, being then required between the switches, while the substitution of simple for two-way switches represents a further advantage. The use of but one switch wire is possible when a convenient and short connection can be made to the main conductors as indicated by the dotted

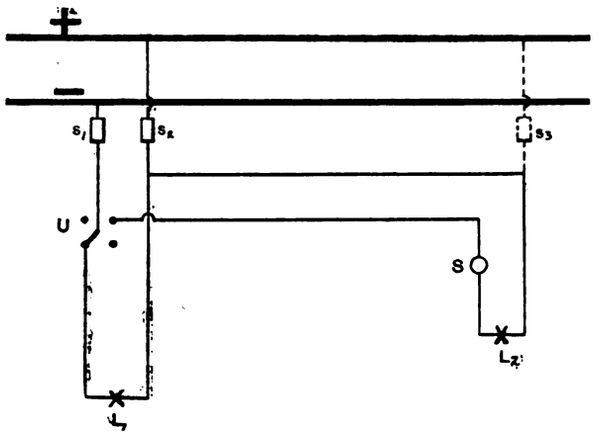

Fig. 3.

line in Fig. 2. But this involves the introduction of a third fuse, s_3, whose maximum capacity, together with that of the parallel fuse, s_2, must not exceed that of the lamp lead, l. This arrangement enables the lamp, L, to be switched on from either of the two positions, but both switches must be set in the off position before it can be extinguished. In order to obtain maximum convenience from the arrangement it must, therefore, be remembered to set the door switch to the off and the bed-side switch to the on positions respectively before retiring. Another arrangement frequently met with includes two lamps so connected that only one can be used at a time. A suitable, and at the same time simple, means of accomplishing this end is illustrated by the diagram (Fig. 3). It is assumed here that one of the lamps, L_1, serves for the general lighting of the room, while the other, L_2, is fixed near the bed or writing desk, but in any case may be extinguished through a switch, S, placed within convenient reach of the bed. Referring to the diagram, it will be seen that a two-way switch, U, and an ordinary single-pole switch are requisite in this case, while between the two, as in the previous example, two wires are required at the most and frequently under favourable conditions only one. A dotted line is again employed to represent the alternative connection whereby it would be possible in favourable circumstances to effect the saving in question. But in that event it would be necessary to add

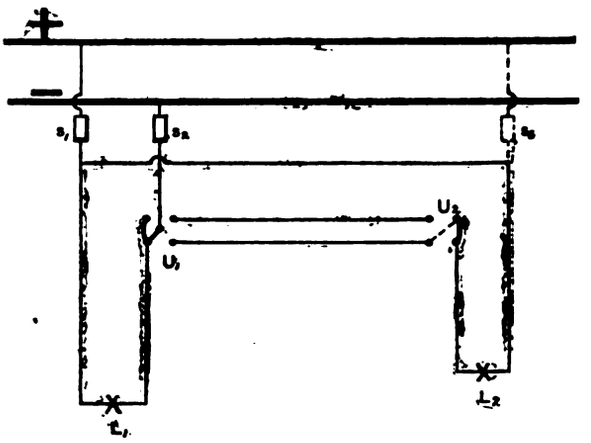

Fig. 4.

a third fuse, s_3, of equal capacity to the other two. When complexity and cost are secondary to convenience the arrangement just described may be modified as shown by the diagram Fig. 4. This modification enables the second lamp L_2 to be controlled—say, from the door switch, when the other switch is in any position. In the case of the arrangement, Fig. 3, on the other hand, with the simple switch s open, it would be impossible to switch on the second lamp L_2 from the door. But, in addition to a greater number of wires the arrangement, Fig. 4, involves the use of a two-way and a three-way switch, U_2 and U_1, respectively. In conclusion, reference may be made to an arrangement for controlling three lamps so that one

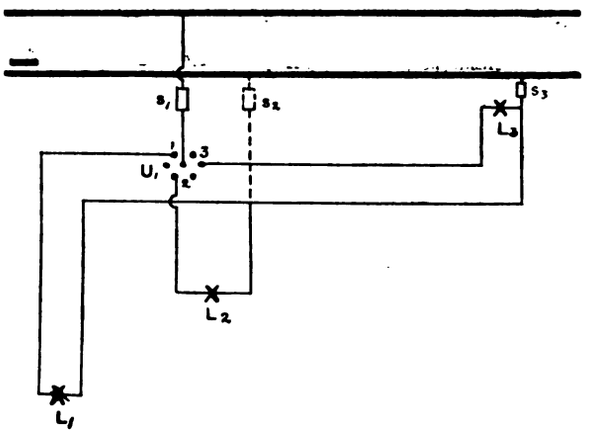

Fig. 5.

only can be used at a time. This condition necessitates the employment of a three-way switch, U_1 (Fig. 5), provided with intermediate dummy contacts, so that in the positions 1, 2, and 3 the corresponding lamps, L_1, L_2, or L_3, are switched on, while no circuits are closed through the dummy contacts. It is assumed that the lamp, group of lamps, or electrolier, L_2, serves for the general illumination of the room, while L_1 and L_3 are desk and bedside lamps respectively. It would be well, adds "A. H.," to provide the last-mentioned, especially the bedside lamp, with separate single-pole switches or switch-holders for local control. The dotted line indicates how a possible saving in wire might be effected. But here, again, this saving would entail the use of a third fuse.

"FLYWHEEL EFFECT" AND "STORED ENERGY" IN ROTATING PARTS OF ELECTRICAL MACHINERY, AND THE PARALLEL RUNNING OF ALTERNATORS.

BY ZODIAC.

The successful operation of electrical machinery, notably alternators and rotary converters, is largely dependent on the steady running of the engines driving the generators, and is, therefore, closely connected with the question of the stored energy in the moving parts. In English practice it is usual to state the kinetic energy of a given wheel in foot-pounds or foot-tons; on the other hand, Continental engineers use the value $G D^2$ as expressing the flywheel effect. The conversion from the one system to the other is a simple matter, but, nevertheless, apt to cause difficulty to the student. The energy in foot-pounds stored in a given flywheel is given by the expression

$$\text{Kinetic energy (in ft.-lbs.)} = \tfrac{1}{2} M v^2,$$

where M = the mass of the wheels in poundals and v the velocity in feet per second.

If D = the effective diameter of the wheel (gyration) and n = the speed in revolutions per minute,

$$V \text{ (in feet per second)} = \frac{D \pi n}{60}$$

D being in feet. If W = the weight of the rim in pounds,

$$M \text{ (in poundals)} = \frac{W}{32\,2}. \quad \text{In C.G.S. units } M = \frac{G}{9\,81},$$

G being the weight in kilogrammes.

The Continental method is to express the "flywheel effect" (not the kinetic energy) in terms of $G \times D^2$, G being the weight in kilogrammes and D the effective diameter in metres, $G D^2$ being given in kilogramme-metres^2. If we express the weight in pounds (as W) and D in feet, we get the expression $W D^2$ in pound-feet^2. The comparison of the two systems will be rendered easy if the expressions are written thus:

$$\tfrac{1}{2} M v^2 \text{ (in ft.-lbs.)} = \frac{1}{2 \times 32{\cdot}3} \times \left(\frac{\pi n}{60}\right)^2 W D^2 \quad (1)$$

or in kilogramme-metres

$$\tfrac{1}{2} M v^2 = \frac{1}{2 \times 9{\cdot}81} \times \left(\frac{\pi n}{60}\right)^2 G D^2 \quad . \quad (2)$$

The conversion from kilogramme-metres to foot-pounds is, of course, a simple matter: kilogramme-metres $\times$ 7·2178 = foot-pounds. Working out (1) for a wheel running at 600 revolutions, we get

$$\frac{M v^2}{2} \text{ (in ft.-lbs.)} = 15{\cdot}3 \times W D^2.$$

A useful rule for converting $G D^2$ (in kilogramme-metres^2) into $\frac{1}{2} M v^2$ in foot-tons is:

$$\tfrac{1}{2} M v^2 \text{ (in ft.-tons)} = G D^2 \times \text{revolutions}^2 \times 45 \times 10^{-8} \quad . \quad (3)$$

Example.—$G D^2$ = 61,000 kg.-m.^{2}; G = 12,500 kg., or 27,550lb.; D = 2·21 m. = 7·24ft.; speed, 166.

$$M = \frac{27{,}550}{32{\cdot}2} = 855{\cdot}6 \text{ poundals}$$

$$v = \frac{D \pi n}{60} = \frac{7{\cdot}24 \times \pi \times 166}{60} = 62{\cdot}89\text{ft. per second}$$

$$v^2 = 62{\cdot}89^2 = 3{,}955.$$

$$\tfrac{1}{2} M v^2 \text{ (in foot-tons)} = \frac{855{\cdot}6 \times 3{,}955}{2 \times 2{,}240} = 756 \text{ approximately.}$$

Using formula (3) we get

$$\tfrac{1}{2} M v^2 = 61{,}000 \times 166^2 \times 45 \times 10^{-8} = 756{\cdot}4 \text{ foot-tons.}$$

With formula (1)

$$\tfrac{1}{2} M v^2 = \frac{1}{64{\cdot}4} \left(\frac{\pi \times 166}{60}\right)^2 \times 27{,}550 \times 7{\cdot}24^2$$

$$= \frac{75{\cdot}34 \times 27\,550 \times 52{\cdot}4}{64{\cdot}4}$$

$$= 1{,}694{,}126 \text{ foot-pounds} = 756{\cdot}4 \text{ foot-tons.}$$

$G D^2$ is the German expression; the French generally use the letters $P D^2$ (kilog-metres^2). I have adopted the equivalent $W D^2$ for the English units, to avoid confusion.

Two useful rules for finding approximately the energy stored ($\frac{1}{2} M v^2$) in the rotating armature or field magnet of a machine are:

Stored energy in ft.-lbs. =

$$\frac{\text{Weight of armature in lbs.} \times \left(\text{Revs. per min.}\right)^2 \times \left(\text{Mean diameter in feet}\right)^2}{23{,}000}.$$

The above is approximately true for armatures whose diameter is large as compared with their radial depth. For armatures of large radial depth and for field magnets with heavy rims,

$$\text{Stored energy in ft.-lbs.} = \frac{A \times L \times (d^2 - d_1^2)}{60{,}000},$$

A being the average weight per cubic foot of material, L the length of armature or magnet parallel to shaft, and d the external diameter in feet; d_1 is the effective internal diameter in feet as determined from the drawings. One cubic foot of cast iron weighs 450lb., one cubic foot of wrought iron weighs 485lb., one cubic foot of cast steel weighs 500lb.

The average value for the stored energy in flywheels used for electric lighting purposes is three foot-tons per electrical horse-power, and four foot-tons for traction work. In the case of the three-cylinder compound Allis engine at the Glasgow tramways (4,000 i.h.p.), four foot-tons per electrical horse-power at normal speed (75 revolutions) has been allowed. The Borsig four-cylinder tandem of 2,500 i.h.p. shown at Paris, 1900, has 3·6 foot-tons per electrical horse-power, the speed being 90 revolutions.

If F = the permissible fluctuation of energy above and below the normal (in foot-pounds), R the radius of gyration, and f = the fluctuation of speed above and below the normal, expressed as a percentage of the normal speed, then

$$F = \frac{W R^2 n^2 f}{587{,}500}, \text{ and } W = \frac{293{,}750\ F}{R^2 n^2 f},$$

W being the weight of the rim in pounds.

The permissible *speed variation in one revolution*, or the "*cyclic irregularity*," is dependent on the frequency employed; for a given speed, the higher the frequency the better must the engine be as regards uniform turning moment. Electrical considerations demand that at any load the phase displacement shall not exceed a given value; for instance, with rotary converters two electrical degrees—*i.e.*, the maximum angular displacement of a given point on the rotating part of the alternator either ahead (+) or behind (−) that position which it would occupy if running at a uniform speed, shall not exceed

$$\frac{2\text{deg.}}{\text{Number of pairs of poles}},$$

in other words, two electrical degrees.

Take, for example, a 50-cycle alternator running at 250 r.p.m., the number of pole pairs would be 12, and the maximum "cyclic irregularity"

$$= \frac{2\text{deg.}}{\text{Number of pairs of poles}} = \frac{2}{12} = \tfrac{1}{6}\text{deg.}$$

In other words, in order to ensure that the electrical displacement shall not exceed + or − 2deg., a point on the rotating magnet system of this generator must not vary + or − more than 0·16 of a degree from the point corresponding to absolute uniform rotation. The total "cyclic irregularity" or angular variation would be from minus 0·16 to plus 0·16—*i.e.*, 0·32deg. Suppose, now, the frequency be reduced to 25 cycles—*i.e.*, a 12-pole machine (six pairs of poles)—the cyclic irregularity would now be $\frac{2}{6} = \frac{1}{3}$deg., and the total angular variations from −0·33 to +·33 = 0·66deg. Hence the 50-cycle machine would obviously require a much larger flywheel effect as compared with the 25-cycle machine if coupled to the same class of engine.

From this it will be evident that with a given engine speed, the lower the frequency the better the parallel running, because a low frequency means a smaller number of poles, so that any speed variation per revolution causes a smaller phase displacement between the E.M.F. waves of the various alternators in parallel. Similar considerations

Digitized by Google

point to the advisability of using high-speed engines for alternator driving. Steam-engine builders usually state the speed variation in one revolution—*i.e.*, the total variation above and below the mean speed—1 in 250 to 300 being a usual figure for two-crank slow-speed engines, this being equal to a total (– to +) angular variation of $\frac{360 \times 1}{250} = 1{\cdot}44$deg. For gas-engines the coefficient of cyclic irregularities should not exceed 1 in 300.

When two alternators are running in parallel, one may be ahead and the other behind by the maximum "cyclic irregularity" so that the two E.M.F. waves will differ by twice this amount, as regards being out of phase. The synchronising current flowing between the two machines will be proportional to the sine of this total angle of phase displacement; assuming each machine leads and lags 2deg. respectively, the synchronising current will be proportional to the sine of 4deg. With well-designed engines and alternators the synchronising current flowing alternately from one alternator to the other should not exceed 5 per cent. of the full-load current of one generator.

Theoretically, the alternator armature impedance should be small and the ohmic resistance equal to the reactance, in order that the synchronising tendency shall be as large as possible. Practical considerations, however, do not allow of this condition being complied with; modern alternators have an armature reactance from 16 to 20 times their armature resistance, the synchronising effort under these conditions being found to be sufficient in practice. While Continental practice allows a pressure drop for the alternators of from 16 to 20 per cent., it is unfortunately too common for English engineers to demand pressure drops as small as 10 per cent. Alternators having such small pressure drops are almost certain to give trouble as regards parallel running, and, as a matter of fact, serious trouble has been experienced in certain tramway generating stations using alternators with low-pressure drops owing to paralleling difficulties.

When two or more alternators are running in parallel, there is always a tendency for oscillations in the relative motions of the generators to take place, to the detriment of the good parallel running of the machines. This oscillation or swinging phenomenon is very likely to take place if there is a considerable cyclic irregularity in the engine turning moment, and especially if this has a time period nearly equal to the natural period of the alternator swing. The time taken for one of the alternators to make a complete swing is given by the equation

$$P\,t = 2\sqrt{\frac{I}{T}}$$

where $P\,t$ = the time of one complete swing in seconds; I = the moment of inertia of the alternator's moving parts (one machine); and T = the restoring torque in pound-feet per radian of displacement. The synchronising power is proportional to the sine of the angle of displacement.

In order that the parallel running of the plant may be satisfactory, $P\,t$ must be greater than the time of one revolution. In the case of an existing defective plant weight must be added to the flywheels so as to increase the value of I, thus, of course, increasing $P\,t$. Two alternators running in parallel can be compared to two pendulums (friction being neglected) whose bobs are coupled together by a spiral spring. If these pendulums are displaced from the vertical, the one to the left and the other to the right, the stretched spring will tend to pull the two bobs together (thus acting as a synchronising current) again. When, however, they do get to their original position, they will have acquired so much kinetic energy that they will overstep the mid position—*i.e.*, vertical—and rush on until they are again inclined to the vertical, only in the opposite sense. This swinging to and fro will continue until the energy has been spent in stretching the spring and overcoming friction. Such oscillations (assuming well-designed engines) are generally due almost entirely to the governors. The governors should be separately adjusted, so that not only is the no-load speed of all the sets the same, but the percentage drop in speed for small changes of load must be identical for the various engines. The drop in speed from no load to full load should be about 5 per cent.—*i.e.*, the governing should not be too close or the load will not be properly distributed. If the drop in speed is very small, say 1 per cent., the governors will be so sensitive that they will respond to small unavoidable momentary speed variations, tending to cut off steam as the speed rises, and to make the cut-off later as the speed falls. Hence there will be an oscillation of the governor system. If the periodic time of the governor oscillation is less than or equal to that of the generators, the governors will successfully follow the oscillations of the plant, and the steam distribution will be such as to damp out the swinging and keep the generators in parallel. If, however, the periodic time of the plant is smaller than that of the governor, it will be unable to follow the generator oscillations, and will lag behind by as much as half a period. Under these conditions steam will be admitted when it should be cut off and *vice versâ*; hence the oscillations are not only kept going, but are actually increased by the lag of the governors so that the generators become unstable and any rotaries on the circuit are liable to "hunt" badly. The remedy is to fit oil dash-pots to the governors, so that, while they will take care of any permanent speed variation, they are prevented from responding to slight quick changes in speed. Air dash-pots are very little use in this respect. The desired "cyclic irregularity" should be obtained by careful engine design and suitable dashpot governors rather than by the use of excessive flywheel effects. In future there is no doubt that the use of damping coils, amortisseurs, and equalising transformers will be much more general than at present; on the other hand, to scotch up good (but too sensitive) governors, as is done in more than one English alternating-current station, is simply to throw away one of the most useful aids to good parallel running of the plant.

DETERMINATION OF THE SPECIFIC ELECTRICAL RESISTANCE OF COAL, ORE, ETC.

BY G. C. WOOD, B.SC.

The following is an abstract of the above interesting paper, which was read recently before the Institution of Mining Engineers at Newcastle-on-Tyne. The paper was introduced by a preface by Prof. H. Stroud, M.A., D.Sc., which reads as follows:

Last summer it appeared to the council of the institute that it was very desirable to have an accurate knowledge of the electrical resistance of coal as well as of the rocks above and below any given seam of coal. No data being available, Mr. G. C. Wood, Durham County Council Scholar of the Armstrong College, was asked to undertake an investigation of the specific electrical resistance of coal, ores, etc., and suitable examples were obtained for experiment. The experiments have been carefully carried out by Mr. Wood, and the results obtained are of considerable practical interest. The specific electrical resistance of coal for the cases examined is, in comparison with the layers above and below the coal, exceedingly high; in fact, so high that coal may be regarded as a very fair insulator. This fact, among others, is one worthy of note in connection with electrical work underground. When the coal is damp the conductivity is practically wholly due to the water present. Mr. Wood has recently been determining the specific resistance of a carboniferous limestone from the Barton quarries, near Darlington. This limestone has been found very suitable for use as ballast on electric railways employing a live rail. The substitution of this limestone for the coke-breeze at first used on the electric lines of the North Eastern Railway Company, has, the writer understands, practically prevented any danger to persons coming into accidental contact with the live rail, provided that there is not a simultaneous contact with the earthed running rail. There is also included a test of the specific resistance of a block of cement-concrete, composed of 2½ parts of crushed brick to one of Portland cement: the crushed brick comprising equal parts of fire-brick (waste from coke ovens) and common brick (waste).

Introduction.—The samples of coal, ore, etc., used in this investigation may be grouped as follows: (1) Coal, and the rocks lying immediately above and below; (2) ironstone, and the rocks lying immediately above and below; and

Digitized by Google

(3) lead-ore and the adjacent rocks. In order to obtain the electrical resistance of the coal, ores, etc, the specimens were worked into shapes with parallel faces. A paste of black-lead and water was spread evenly on the faces and dried. A copper plate was cleaned, on this was laid a sheet of tin foil, and on this again was placed the sample with one of its blackened faces on the foil. On the top of the specimen was placed another sheet of tin foil, and then another copper plate. Thus contact could be established at the two copper plates, and such a weight was laid on the top as experiment showed would make good contact. The method employed in the measurement of the samples was one or other of the following: (*a*) Wheatstone bridge; (*b*) high-resistance substitution; and (*c*) the high-resistance leakage. The specimens of coal examined were supplied from the Cowpen, Harton, and Murton collieries. The iron-stone was supplied from Skelton Park mines. The lead-ore examined was supplied from the Greenside mines, near Penrith.

The author describes in detail the experiments made on six kinds of coal as obtained from the three collieries mentioned in the Newcastle district. The actual figures will be found in the table which appears below. In order to show the method of procedure we give the following details of the experiments made on the Cowpen Colliery coal. The specific resistance (1) of the black shale roof was determined by the (*b*) method with a piece with an area of 130·4 square centimetres and a thickness of 1·2 cm., and was 4,090 ohms, and the specific resistance was 444,800 ohms per cubic centimetre. The resistance of another piece with an area of 29·8 square centimetres and a thickness of 1·12 cm., was 16,800 ohms, and the specific resistance was 446,400 ohms per cubic centimetre. The mean specific resistance was 445,600 ohms per cubic centimetre.

2. *Coal*.—The sample of gas coal supplied from this colliery was of such a shape and so easily worked that one piece was obtained of fairly large cross-section. The resistance (method *c*) of a piece with an area of 96·3 square centimetres and a thickness of 3 cm., was 1,120 megohms, and the specific resistance was 36,000 megohms per cubic centimetre.

3. *Grey Sandstone Thill*.—The resistance (method *b*) of a piece with an area of 30·2 square centimetres and a thickness of 2·8 cm. was 1,900 ohms, and the specific resistance was 20,500 ohms per cubic centimetre. The resistance of another piece with an area of 18·4 square centimetres and a thickness of 1·2 cm. was 1,310 ohms, and the specific resistance was 20,100 ohms per cubic centimetre. The mean specific resistance was 20,300 ohms per cubic centimetre.

The experiments on the ironstone and its surrounding strata were carried out in the same way, and the experiments on the lead ore were likewise similar. In this case, however, smaller samples were used. The results obtained with direct current and small voltages were confirmed by other experiments, using variable current in a Wheatstone bridge method. In this case a telephone took the place of the galvanometer, and a microphone was inserted in the battery circuit. Other experiments with voltages of 100, 200, and 220 volts were used for determination of the resistance of the samples which were connected in series with the voltage and with a tangent galvanometer. For all the specimens that could be measured this way it was found that there was practically no difference from their resistances as abtained above. The samples of coal had too high a resistance to be determined by this method. From an examination of the results of the tests, as given in Table I., it will be seen that lead ore is the only ore which, by practical tests based on differences in electrical resistance of large masses, could, with certainty, be distinguished from its surrounding rocks. It may also be noticed that coal, and especially hard steam coal, has a comparatively high electrical resistance. This important result should be borne in mind in connection with practical work. The following values in megohms per cubic centimetre indicate the magnitude of the specific resistance of coal and other well-known bodies: Gutta-percha, 400,000,000; arc-light carbon, 0·000,000,004; and coal, say, 40,000. Coal has, consequently, 10 million million times greater resistance than arc-light carbon, and 10 thousand times less resistance than guttapercha of the same dimensions.

The author had previously experimented with the carboniferous limestone used as ballast on the North-Eastern Railway, and found a specific resistance of 1,014,000 ohms per cubic centimetre. A piece of cement concrete flooring was found to have a specific resistance of 754,000 ohms per cubic centimetre.

TABLE I.—Specific resistances of Minerals found in Mines.

Name of mine.	Description of mineral.	Specific resistances per cubic centimetre (ohms).
Cowpen	Roof: black shale	445,600
Ditto	Gas coal	36,000,000,000
Ditto	Thill: grey sandstone	20,300
Harton	Roof: black shale	357,500
Ditto	Steam coal: top panel	80,100,000,000
Ditto	Ditto bottom panel	*
Ditto	Gas coal	33,000,000,000
Ditto	Coarse coal	3,395,000,000
Ditto	Thill: bluish-grey posty shale	105 900
Murton	Roof: soft blue shale	432,900
Ditto	Coal	33,900,000,600
Ditto	Thill: blue shale	13 000
Skelton Park	Roof: dogger rock	52,100
Ditto	Ironstone	157 000
Ditto	Thill: bottom rock	52,050
Greenside	Lead ore	7½
Ditto	Old red sandstone	8,375 000
Ditto	Mountain limestone	2,900,000

* This value is omitted from the table, as the specimen contained iron pyrites.

OBITUARY.

We regret to announce the death at Westcliffe-on-Sea of Mr. E. W. Langdon, who was for many years chief of the Midland Railway electrical department at Derby. Mr. Langdon, who was 73 years of age, was educated at the Royal Naval School, New Cross, and afterwards joined the staff of the Electrical and International Telegraph Company, and served at Winchester, Portsmouth, and Southampton. When the telegraphs were transferred to the State, Mr. Langdon became head of the electrical department of the London and South-Western Railway, but in 1878 he became head of the Midland Railway department at Derby, which office he held until about a year ago. Although his chief work in connection with the Midland Railway had to do with telegraphy and signalling, Mr. Langdon took from the first a very great interest in electric lighting. The plants laid down by him for lighting the principal stations on the railway were remarkable for their completeness. The results obtained from working these stations were placed at the disposal of the whole profession, and formed an interesting guide as to what could be done with isolated plant in the way of cheap production. Mr. Langdon also took a great interest in the electric lighting of trains, and was responsible for the introduction of one or two systems for the Midland Railway Company. In connection with the Institution of Electrical Engineers, Mr. Langdon displayed his versatility and interests. He held at various times nearly every office possible, and was in the early days the secretary of the Institution for some years. He occupied the presidential chair in 1901-2. It was, however, in his contributions to the *Transactions* of the Institution that he showed the wide range of his engineering knowledge. Papers will be found from him on practically every subject connected with electrical engineering. His views on the electrification of main line railways, as set forth in the papers read a few years back, led to most interesting and valuable discussions. His death will be much regretted by all who had the privilege of knowing him.

APPOINTMENTS VACANT.

Electrical Engineer, Llandilo Urban District Council, to take charge of lighting station for one year from Sept. 30 next. Applications before 22cd inst.

Electrical Engineer with experience in armature winding. Apply Light Electric Motor Co., Ilford. See advertisement.

Assistant Engineer, Handsworth Urban District Council. Salary £100 per annum. Applications by 30th inst.

SOMETHING OF A SCANDAL.

Statisticians love figures, but the figures they present to us are often of little use. Could not some of these dry-as-dust gentlemen obtain information of a definite character as to the cost of parliamentary operations? It has been estimated by men who have the best opportunity for knowing the ins and outs of the whole question that the abortive proceedings in regard to the Power Bill brought before Parliament this session has cost supporters and opponents together something approaching one hundred and fifty thousand pounds. One hundred and fifty thousand pounds is a tidy sum, and would be enough to equip a fair-sized installation. Indeed, the possession of such a sum would make many a reader give up work and take to pleasure, thinking himself one of the favoured men of the earth. When we come to inquire what really is the outcome of this huge expenditure, it is hard to say with any degree of accuracy. A good deal of advertisement, a good deal of preliminary work will not have to be done again, but otherwise the money is lost, and the result is nil. There is no question as to agreement with the promoters of this particular Bill. That is not the question, which is of far wider import, and may be stated—as to whether, under all circumstances, the existing costly methods of procedure to get an opposed—nay, even an unopposed—measure through Parliament are not something of a scandal. This is no new topic for discussion. In the abstract everybody admits that reformation is needed, but concretely everybody who has any power in the matter is against reform. It can hardly be expected that agents, lawyers, or experts, who largely divide the money among them, should be eager to change a system which brings so much grist to the mill. These men naturally have no great incentive to press a change, and, therefore, it is difficult to see how any reform can be brought about. One of the causes leading to the existing state of things is in the number of authorities that have a voice in the question. Each authority, of course, has its say in opposition, and here is where so much money goes. Again, the number of authorities bring about difficulties of reform. A tramway scheme interferes with quite a number of authorities, and it is but reasonable that those who are to be interfered with should be heard on the matter. On this point if reform is to come about it will be by superseding a number of authorities by a central authority, as suggested by the late Commission on London Traffic. The London County Council is the central authority for the sewerage of the metropolitan area; if similarly a central authority was answerable for the construction and the maintenance of roads and streets, that would be the one authority to be heard about a scheme—tramway or otherwise — likely to interfere with the streets, and by a simplification of this kind a large part of the parliamentary costs would be avoided. It is, perhaps, not generally understood that the costs of the opposing authorities, as in the case of the Power Bill, have to be borne by the rates of the districts; and the summation of the various amounts paid by authorities over the London area alone in opposition to a variety of schemes is a huge total, so that the question must not be looked at solely from the side of the promoters. In the case of a scheme ultimately decided to be a suitable one, and one forming a link in the chain of modern progress, these preliminary expenses form an item in future balance-sheets that may seriously handicap the undertaking. Scores of good schemes are wrecked by inflated capital, and anything that can be suggested by way of reform to minimise these expenses should be welcomed. Is it possible to suggest a practical solution

Digitized by Google

for the abolition of such a costly scandal? At least one point of reform can be urged—that any Bill passing and not getting further than the Committee stage should be automatically continued from that stage during the next Session, and the whole process not have to be commenced anew.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

TELEPHONE PURCHASE.

SIR,—The late vote in the House of Commons possibly settles the telephone policy of the country definitely, but in view of the active part I have taken in the telephone question in the past a few remarks from me may be permissible. Although the municipalities are to be excluded in the future from participation in telephone enterprise, yet it will not, I think, be seriously contested by any unbiassed person who has given attention to the subject that such progress as has been made, either in the direction of efficiency of service or reductions of rentals, must be credited to the municipalities. When they entered the field the telephone service of the country, whether conducted by the Post Office or the National Telephone Company, was in a deplorable state of inefficiency, and the rates all round were high, such competing companies as had endeavoured to improve matters in this respect having been nobbled by the overpowering monopoly. Even the existing Post Office exchange in London is the outcome of municipal action, for it was established by the Post Office only as a last resort to prevent the London County Council and the City Corporation from undertaking the task themselves. As soon as the establishment of a municipal exchange in Glasgow became an assured fact the National Telephone Company introduced toll rates and party-line rates all over the kingdom, hoping thereby to soothe the prevailing discontent, and, by yielding a good part of what the voice popular demanded, to diminish the tendency towards competition. By this move they qualified to some extent their former prohibitive flat-rate charges, which excluded small users from participating in the benefits of the telephone. These lower charges and the consequent spread of telephones are boons which the whole country owes to the few courageous municipalities which decided to defy the Jabberwock. At the same time the company made gigantic efforts to improve its service, most markedly in Glasgow and in other towns where competition was either assured or threatened, and for the first time in its history began to condescend to take some note of the wishes of its subscribers. Had it not been for the municipal action the prohibitive flat rate, without toll rates and without party line rates, would certainly have been insisted upon for years yet to come. Much has been made of the fact that but few of the municipalities took advantage of the Act of 1899. But it must not be forgotten that several of the provisions of that Act bore heavily against the corporations, for by it they, as competitors, were saddled with terminal fees, compelled to continue wayleaves in perpetuity, and forced to consent to an extension of the company's existence for a period equal to their own license. These disabilities were serious enough to render municipalities cautious, and on the top of them came the campaign inaugurated by the company at the very birth of the very first municipal exchange, in which was employed every means, fair and unfair, to ridicule, disparage, and misrepresent the municipal undertakings. The people of Tunbridge Wells were engineered into a panic and foolishly sold their infant exchange when success had been already assured. This extraordinary event naturally had the effect of keeping other municipalities back, but it could not succeed perpetually. When the various Corporation undertakings were quite new and could only publish accounts covering a broken year, or a first complete year, these tactics were successful, but when several years had elapsed, and the municipal undertakings, instead of collapsing as predicted, continued to progress and to show favourable financial results, it became necessary for the company to adopt some other means, for if the municipalities were given further rope, it was known that they would demonstrate, without any question whatever, that low telephone rates were compatible, not only with efficiency, but with every financial requirement; and that the result which was staved off in the first instance by misrepresentations, was bound, sooner or later, to emerge—that is, that the Corporations generally would take up the telephone just as they did the electric light after several years' inaction, owing to dubiety as to whether electric light undertakings could be made to pay. In such an event the company could not have survived, as everything has shown that it is not able to compete successfully with the municipalities. To maintain its position or increase the number of its subscribers in the competing areas the company has had to give preferences and to charge only a few shillings a year, and frequently nothing at all for its telephones, with the result that it is working at a loss wherever it has to compete with a municipality. Under these circumstances the policy was changed and the company threw up the sponge. Knowing it could not compete, it decided to sell its undertaking to the Post Office, and has, unfortunately for the country, succeeded. Rightly read, the sale is an admission of defeat and a resort to a forlorn hope, for by no other means could the dreaded municipal competition be averted. The company has run away and sheltered behind the Post Office. Some day, probably, these facts will be recognised, and then the debt which the country owes to the few courageous Corporations will be estimated at its proper value. By the sale which has been approved by Parliament monopoly has been re-established, and with it the country will have to suffer all the usual consequences, including inefficiency and high rates. Already, in order to make the company's plant admissible for purchase, a much lower standard of efficiency than has prevailed with the Corporations has been set up by means of a specification permitting of cheap and nasty work. The inefficient system which the Post Office have set up in London will probably be extended all over the country; invention will be discouraged and progress disowned. Once the Post Office has spent its money in putting in apparatus, whether it is good or bad, nothing will be put out of use, because the Post Office will never scrap old apparatus if it can help it. One of its most cherished prejudices against the telephone in the early days was that its extension would cause the scrapping of the many thousands of A.B.C. telegraph instruments of which the Post Office was then possessed.

The municipalities before the Select Committee made a gallant effort to prevent the country from falling into these various errors, and succeeded so far that the committee, appointed by the Government itself and consisting chiefly of Conservative members, were convinced, and recommended that the beneficent municipal control should continue and be extended. It is remarkable that two separate committees, investigating at an interval of seven years, agreed practically on the course they considered the best to adopt. But the Government set aside its own Select Committee when it found that it did not report in accordance with its wishes, and by a party vote following on a feeble discussion in a half empty House, before the evidence presented to the Select Committee had been circulated, committed the country to an expenditure unknown in amount and to a perpetual monopoly.

The inconsequence of the debate may be exemplified by the fact that when the Postmaster-General said that the company had definitely decided not to accept the agreement if new municipal licences were granted, no member reminded him that by Clause 14 of the agreement the Post Office had specially reserved the right to grant such licences, and that consequently the refusal of the company really meant a demand for the suppression of a part of the agreement—viz, Clause 14—which it had already signed.

There are grounds for thinking that the six local authorities owning telephones have reason to fear that it is not the intention of the Government to treat them fairly, but that, in return for the loyal assistance they rendered in aid of the Government's declared telephone policy of 1898, they are to be treated shabbily, and, if possible, caused to lose at least a portion of the capital they have invested on

Digitized by Google

the faith of Government pledges and guarantees.—Yours, etc.,
A. R BENNETT.

Westminster, S.W., Aug. 15, 1905.

THE FIFE ELECTRIC POWER COMPANY, LIMITED.

On Tuesday last the first generating station for the general supply of electricity under the Fife Power Company's Act of Parliament, 1903, was opened. This pioneering station is situated near Dunfermline, in the centre of a large weaving industry. It is also in the coal-producing area, which extends over a large portion of the power company's district. Hence cheap coal is available, and this is delivered by rail to the present station.

A somewhat unusual course was adopted by holding the annual general meeting of the company in the generating station, immediately preceding the opening ceremony—several visitors from neighbouring factories, collieries, and works of all kinds being present. As soon as the formal business was disposed of, the chairman, Mr. R. E Walker (of the firm of R. E. Walker, Reid, and Co., Dunfermline), made a speech explaining the present position of the company and its prospects for the future. He then started the two main engines and the two exciter engines, thus practically putting the whole of the machinery of the generating station into operation, and proving to the complete satisfaction of the company present that the plant was really completed and in perfect order, and ready for commencing the supply of power to the district.

The CHAIRMAN in his speech referred to the fact that the coal industry was, at present, somewhat depressed, but expressed the opinion that it would, no doubt, soon revive, and that cheap power would greatly assist this desirable end. He pointed out that the development of a power company was bound to be a slow process, as even after orders from consumers were booked, the delay which occurred in the consumers themselves settling their contracts for the necessary motors for their own premises, and in the work of erection, frequently extended over many months. He alluded to the prospect of supplying power to tramways, which another company will probably be shortly constructing in and around Dunfermline. He also mentioned that negotiations for supply in bulk to the Dunfermline Corporation were proceeding. While he could not say more at present, he would venture the opinion that the extremely generous offer which his company had made to the town was such that it would be difficult for the town to go past the company and erect their own works.

The chairman afterwards called upon Mr. W. A. CHAMEN (previously electrical engineer to Glasgow Corporation, and now representing Messrs. Bramwell and Harris, the consulting engineers) to explain some of the points regarding the machinery, which he did, pointing out at the same time some further possibilities which lay before the power companies, by means of which the whole face of the country might be transformed, both from a residential and industrial point of view. He referred to the fact that the contract for the equipment of the generating station had been carried out by Messrs. Bruce, Peebles, and Co., Limited, of Edinburgh.

Mr. T. O. CALLENDER, at the request of the chairman, next spoke in the capacity of contractor for the mains, which have already been laid from the generating station into Dunfermline. He spoke of the extremely promising prospects which lay before the Fife Company, and in the course of his remarks referred to the fact that Mr. Miller, the convener of the Wishaw Electricity Committee, and Mr. Cox, the engineer, were present, and that they represented the first town in Scotland to make an agreement with a power company—viz., the Clyde Valley Electrical Power Company—for supply in bulk.

These two gentlemen afterwards spoke, giving information respecting the arrangements referred to by Mr. Callender, and expressing their satisfaction therewith. They both considered that for small towns to put down their own generating stations was an extremely unwise and expensive plan to adopt, when supply at cheap prices from a large power company could be had for the asking.

The generating station, which is only a pioneer one containing 1,000 h.p. of generating plant, we hope to describe fully in a later issue. Meantime, we may say that it is very neat and compact, and is equipped in a way which will enable a supply of power to be given on economical and business lines.

MACHINES AND SWITCHBOARD FOR A LABORATORY.

BY E. SMITH, B.SC., A.R.C.SC.

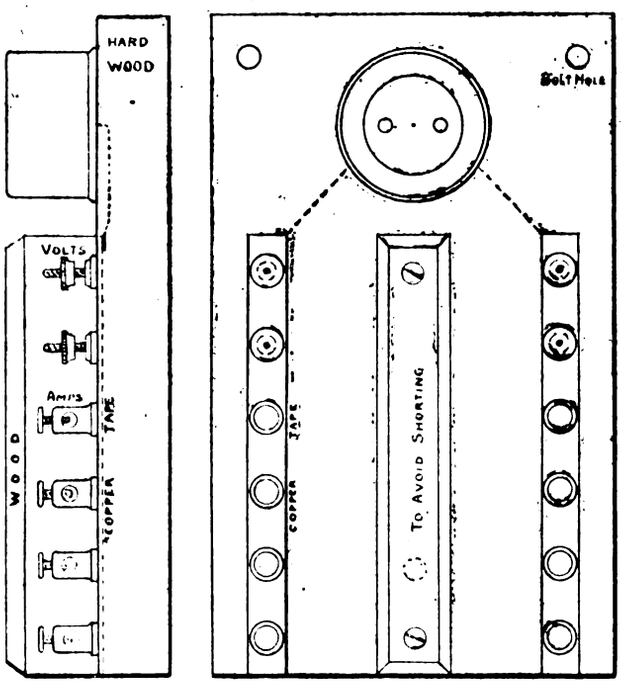
The experiences met with in providing apparatus for a course designed to extend beyond the ordinary grade of the City and Guilds are responsible for the following notes on suitable machines, switchboard, and apparatus. The set given will be found to be very complete for elucidating all the necessary technical points. It is really suitable for a class of about 12 students where the lecturer is without assistance. Six students would work on the machines one evening and take ordinary laboratory work the following week. This set would also be useful as a demonstration group to bigger classes in a larger laboratory. Objections might be made against the continued use of the same machines, but there is a great advantage in learning the principles of the subject, step by step, on well-known machines. The point at issue is not forgotten amongst the difficulties of connecting up to strange apparatus. The ordinary student meets with many different types in his daily work, and very probably deceives himself by his superficial knowledge. It is almost unnecessary to state that the student should be given all possible data about the machines at the start, and that working drawings should be provided with every machine. There should be an ammeter and voltmeter available for every circuit. Ammeters are now both good and cheap, and there should be no economy practised on them.

Machines.—The machines suitable for a direct-current supply are three in number. One 2-b.h.p. four-pole converter, shunt-wound, 1,500 r.p.m.—therefore, ~ 50. The field winding should be provided with a rheostat whose resistance is half that of the field coils. Six slip-rings, giving single, three, or four phase. One 1-b.h.p four-pole converter, shunt-wound; field rheostat to have a resistance four times that of the shunt coils; 1,500 r p.m., with all resistance cut out, ~ 50. Six slip-rings like the larger machine. Series windings also should be provided; the ampere-turns at full load approximately equal to those of the shunt coils. It would be an advantage to have the series coils arranged in pairs, which could be placed either in series or in parallel. The axle should carry a contact disc at its commutator end. Each machine is to have a broad pulley, the two pulleys to be facing so as to be coupled together by a semi-flexible connection. If the voltage on the direct side be between 100 and 200, the supervision of the switchboard with young students can be less strict. One ·25-b.h.p. three-phase induction motor, with wound rotor and slip rings and a generously designed three-way rheostat for the rotor. The flexibility of a three-phase motor for teaching purposes is quite remarkable. This motor should also be provided with a pulley, and so placed that it can be driven from one of the other machines by a belt. The above machines form a complete and compact set, and can be obtained at a reasonable price, as they have no peculiarity of design. A combined and convertible series-repulsion motor, 1 b.h.p., at a reasonable price, would be a boon for teaching purposes. With the other direct-current and alternate current type of motors at present available this, however, is not to be expected.

The Switchboard.—The switchboard, of which a somewhat detailed diagram is given, practically explains itself. All the connections can be traced to the machines, and those for the experiments are all to be made on the front of the board. The motor connections, which are quasi-permanent, can be taken through holes and along the back of the board. The machine terminals to be used are either marked in large letters or figures. The six alternating-current terminals bear figures; 1, 2, and 3, being the three-phase terminals, and 3, 4 and 5, 6, being the single-phase terminals, 90deg. phase apart. S S represent the series

Digitized by Google

turns which can be reversed by the plug and socket arrangement whilst the turns are short-circuited. It has been found extremely useful with beginners to place between any pair of live terminals an upright length of wood, a little higher than the terminals, to prevent accidental short-circuiting. The machine terminals should be on slate or marble, and of the ordinary screw and hole type. The field rheostats should be designed to carry currents continuously. Above the machine panels come two long slabs of slate or marble bearing special connection boards. These do entirely away with careless connections, and allow for any number of connections to one point. The boards may be of any hard wood, and could be soaked in paraffin wax if necessary. They are bolted through on to the slate. One board has been drawn large to show the details. At the top of each is a socket to receive any voltmeter plug. On each piece of copper tape are two-volt connections, which ought to be soldered or fastened to it by a set screw. The current terminals are of the screw and hole type, and furnished with wood screws. A lead washer can be introduced between the base of the terminal and the copper tape to make complete contact.



Connection Board.

The machines should be placed about 3ft. in front of the switchboard, and the latter should stand free from any wall. The cables (all labelled) from the machines should be led into a groove along the floor and taken up in a single-layer group to the middle of the lower part of the board, and then distributed. The resistances for the loads on the transformers could then stand at the sides below and behind the switchboard. The supports to the board have not been indicated. The middle panel bears one of the main supply terminal pairs and also the terminals of the wires which supply the laboratory. This enables alternating or direct currents to be supplied to any bench in the room. A series circuit round a room is invaluable for class work. For example, when a potentiometer experiment is taken with elementary students, if each switch be shunted by one or two secondary cells in series, a fairly constant voltage can be obtained by each worker. Besides, galvanometer and electrolytical experiments can be done with a certainty that is refreshing to a beginner who has just gone through a course in frictional electricity. The voltmeters and ammeters can be mounted on a wooden panel. Each voltmeter is provided with a twin flexible and plug. The low-reading ammeters are provided with cut-out switches, so that they may be placed in series with higher range instruments and cut out when overloaded. The fuses at the side of the connection boards may be used for subsidiary circuits.

The top of the switchboard forms a shelf, on which extra instruments may be placed if necessary. The hinged shelf at the bottom of the board will be found useful for portable wattmeters, etc. If the board be connected to a town supply it is well to have a small red incandescent lamp to indicate when the top main switch is on.

Instruments.—These should all be numbered and the types should be representative. It would be a great advantage if teaching instruments were provided with transparent fronts. Ammeters with more than one range are to be avoided. One ammeter can only be in one circuit for any one experiment. Voltmeters with more than one range are rather useful, as they can be placed in any circuit at any time. Electrostatic voltmeters to cover the whole likely range are a necessity. The writer fixed a pointer to an ordinary quadrant electrometer for direct voltages up to 40, the reading at which an ordinary electrostatic voltmeter begins, the needle being electrified from the supply voltage. The small alternating voltages had to be read from the mirror indications.

Secondary cells in a small laboratory which is closed for several weeks per year are very troublesome; for larger currents at low voltages, a motor generator yielding about 150 watts at 4 to 8 volts is far more preferable.

Cut Outs, etc.—The laboratory should be provided with a number of connection boards similar to those on the switchboard. The cut-outs, plugs, etc., should be of commercial type, and of a generous size; certainly not home-made. A number of separate fuse blocks should be available.

Cables.—The wires should be of two kinds—twin flexibles of high grade insulation for volt connections, the free ends being provided with contact plates, and one size of cable for current wire, say $^{7}/_{20}$ Temporary connections which are fully visible may have a fairly large current density. The ends of the insulation must be carefully bound in all cases. The ends of the $^{7}/_{20}$ should either be soldered solid or sweated into thimbles. When two cables are joined together they should not be twisted, but connected by proper screw connectors and the junctions wrapped round with tape.

Transformers and Choking Coils.—These are amongst the few things that can be advantageously made in the laboratory workshop. The different coils on the cores should be brought to terminals on the covering board so that various voltages may be obtained. Ordinary hoop iron twisted round into a hollow square does very well for a core. Paper or paraffined paper can be used between the layers. Suitable numbers for the coils are pairs of 50, 100, 100, 500. Thick copper wire and plenty of iron should be used. The coils may be put in parallel for heavy currents.

Resistances.—Lamp resistances fitted with ordinary single-pole switches should be used. They are reliable and constant. Liquid resistances are exceedingly useful where the current must be altered gradually. Coiled iron resistances are cheap, but they give too much trouble with their large variations due to temperature. It is much better to use wire with a negligible coefficient. All resistance frames should be fitted with single-pole switches for cutting out the coils step by step.

WIRELESS TELEGRAPHY MEASUREMENTS.*

BY W. DUDDELL, MEMBER, AND J. E. TAYLOR, ASSOCIATE MEMBER.

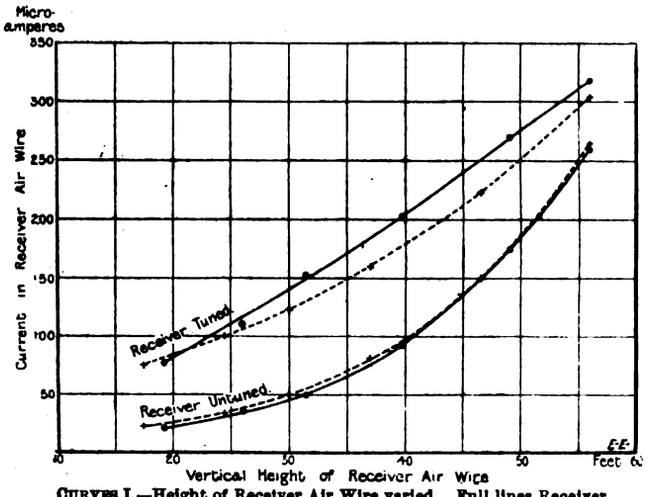
(*Continued from page 197.*)

Height of Receiving Air Wire Varied.—The transmitting conditions were kept constant and the height of the receiving air wire was varied by using vertical wires of different lengths. The receiving circuit was retuned to suit each height of vertical wire by altering the self-induction in series with it. Observations of the received current were made both with the air wire tuned as above and untuned—that is, with no self-induction in series with it. The results are given in Curve I. Taking the tuned results first and the receiver near the fishponds, where the screening of the receiver was comparatively small, the law connecting the height of the receiver air wire and the current in it is practically linear between 30ft. and 56ft.; below 30ft. the current increases less rapidly than the height. With the receiver in the paddock and the air wire suspended from a

* Paper read before the Institution of Electrical Engineers.

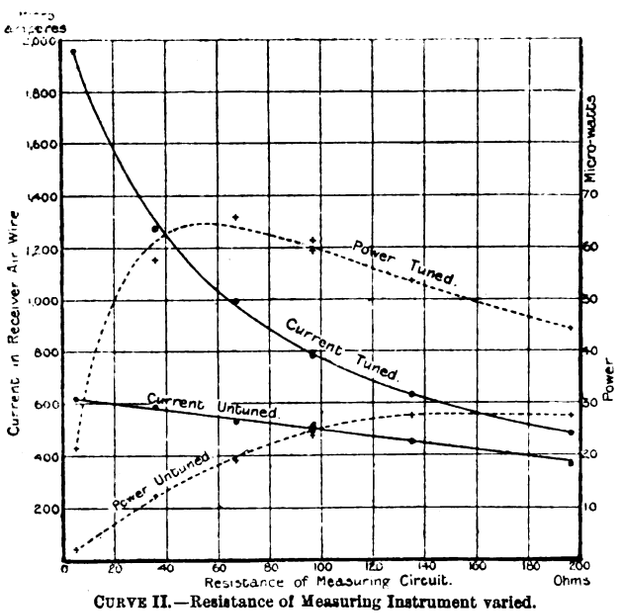
Digitized by Google

spar fixed to the top of a terminal pole so that the lower part of the air wire was screened by the stays and other conductors, the curve between height and current does not become linear even at the top. That there was considerable loss of energy when the receiver was in the paddock is shown by the fact that rather more current was observed when the receiver was near the fishponds and the transmitter at a distance of 2,110ft. than when the receiver was in the paddock and the transmitter 1,588ft. away; or, in other words, equally strong signals were received at one-third greater distance when the receiver was not in



CURVES I.—Height of Receiver Air Wire varied. Full lines Receiver near Fish Ponds. Dotted lines Receiver in Paddock.

the paddock. It will be observed that the curve of tuned received current in the more screened situation (the paddock) more nearly approaches the shape of the untuned current curves, owing, probably, to the damping losses in the wires, stays, etc., on the pole. This point is not without practical significance, inasmuch as it would indicate that to obtain the sharpest tuning the stay wire of wireless telegraphy masts should be well divided up into short insulated sections to avoid the production of oscillations in them which would cause damping in the receiver. Without the self-induction in the air wire,



CURVE II.—Resistance of Measuring Instrument varied.

increasing the height naturally increases the received current very rapidly, under the conditions of the experiment, as it not only increases the E.M.F. induced in the wire, but also improves the tuning, so that a larger current is obtained even for the same induced E.M.F. The tests were commenced in rainy weather, but nearly the whole of the results given were obtained in dry weather. No considerable effect on the strength of the received signals was noticed when it changed from wet to fine.

Resistance of Measuring Instrument Varied.—In order to investigate the effect that the resistance of the measuring instrument in series with the receiver air wire had on the

value of the received current, a low resistance (5·55 ohms) heater was placed in the thermo-galvanometer and additional resistances were used in series with it so as to increase the resistance as required. Each of these resistances consisted of a single Λ-loop of (0·001in.) Kruppin wire, the total length of wire in the longest one, which had 99 ohms resistance, being only 7cm. Not more than three of these resistances were ever used in series with the instrument at one time, so that the self-induction and capacity effect of these resistances was probably small. The total resistance—that is, the resistance to steady currents—of the thermo-galvanometer and above series resistance is given in column 1 of Table IV., and the observed current in column 2. From the observed current and resistance the available power in the measuring circuit has been calculated as $C^2 R$. These values, both for the receiving circuit, tuned and untuned, are plotted in Curve II In the tuned condition, the available power reached a maximum when the receiving circuit had a resistance of about 60 ohms, so that it is evident that this would be the correct resistance to give to any receiver of the thermal type used directly in series with this air wire. The current decreases very rapidly with increase of resistance, and almost exactly according to the relation: Current (tuned) $= \frac{0{\cdot}12}{(56+r)}$, where r is the total resistance of the measuring circuit. With the receiver air wire only, the results may be expressed: Current (untuned) $= \frac{0\,12}{\sqrt{(185)^2+(56+r)^2}}$. The values of the current calculated from the above formulæ are given in Table IV. for comparison with the observed values. The agreement between them is very close. Taking the formula $\frac{0{\cdot}12}{\sqrt{(185)^2+(56+r)^2}}$ the first point to be noted is that it is of the same form as the equation giving the current in an ordinary alternating-current circuit, containing resistance, self-induction, and capacity in series. If in such a circuit the self-induction be adjusted so as to give a resonance $(L\,p - \frac{1}{F\,p} = 0)$ — *i.e.*, the circuit be tuned to the same period as the impressed E.M.F.—then the first term $(185)^2$ will vanish, and we get our "tuned" equation as we find by experiment. To get a good resonance or sharp tuning in such a circuit, it is also necessary that the term $(56+r)$ should be as small as possible. Therefore, to get the best tuning, r should be small, but to obtain the most energy to work the receiving instrument r should be about 56 ohms. If, however, the constant 56 can be reduced, both the sharpness of the tuning and the available power may be proportionately increased. It is, therefore, of great importance to inquire what causes the vertical receiving air wire to dissipate energy as if it had a resistance of 56 ohms. Part, at least, of this effect is no doubt due to radiation, but some part may be due to losses at the earth connection and to eddy-current losses in the oscillating system. It should be observed that when a dissipation factor of this magnitude is associated with the air-wire system it becomes important, if tuning is to be kept sharp in order to obtain the greatest "selectiveness" in wireless telegraphy, to attain the selectiveness by the use of associated resonant circuits in which the damping losses are made very much smaller. Returning to the

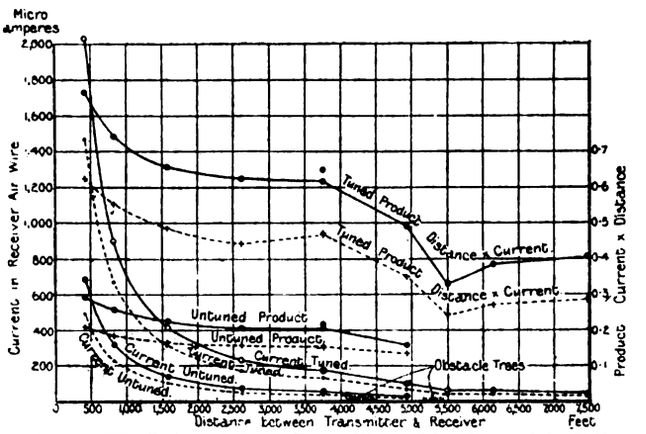
equation for the current, it is seen that the current flows as if an E.M.F. of 0·12 volt is induced in the air wire. Now this is a root mean square voltage, the mean not being taken over the time each set of oscillations continues, but over the time each set lasts, plus the time between it and the next set. It is improbable that the groups or sets of effective oscillations last much more than one three-thousandth of the time interval between them (taken on a basis of 50 effective cycles per train), so that the R.M.S. voltage induced during the oscillations cannot be much less than $0{\cdot}12 \times \sqrt{3{,}000} = 6{\cdot}6$ volts under the conditions of very strong signals used for these tests.

Voltage Produced at Coherer Terminals.—Though no precise measurements bearing on the point were made, it may be taken, in view of the manner in which the coherer receiver used at intervals during the experiments responded at the longer distances, that the E.M.F. of 6·6 volts given in the previous paragraph was about eight times stronger than necessary to get signals on that particular coherer. The critical R.M.S. E.M.F. during each train in the receiver antenna required to operate the coherer would, therefore, be about $\frac{6{\cdot}6}{8} = 0{\cdot}8$ volt. This was not the actual voltage applied to the coherer terminals, however, because the coherer was always connected in a secondary circuit tuned to resonance, in which it may be taken that the E.M.F. was magnified, perhaps, 10 times, giving 8·0 volts per train (R.M.S.). In this secondary resonant circuit a special form of construction has been adopted, and every precaution taken to reduce the damping to a minimum. To get an idea of the maximum voltage attained during a train of oscillations in this circuit, it is necessary to take into consideration the increment and decrement of the train. Allowing for this, it is thought safe to assume that an actual maximum E.M.F. of about four or five times the R.M.S. figure—viz., about 40 volts—should be available in the coherent resonant circuit to give good signals. As in practical work it would be necessary to provide a considerable margin above this figure, it is clear that the maximum voltages produced are not of a very small order.

Energy of Oscillations in Radiating System of Transmitter.—Seeing that it is necessary, in the case of the receiving oscillatory system, to assume a dissipating factor of 56 ohms, it is highly probable that a similar but somewhat larger dissipation factor is involved in the case of the transmitter radiating system. The radiation coefficient should be approximately the same in each case, the systems being similar, but there can be little doubt that dielectric losses and brush discharges due to the high tension at the transmitter would increase the dissipation to some extent. For the purpose of calculating the energy of the transmitter oscillations, the dissipation factor is, therefore, assumed at a venture to be 60 ohms, and the following figures are obtained for the different waves used in the experiments:

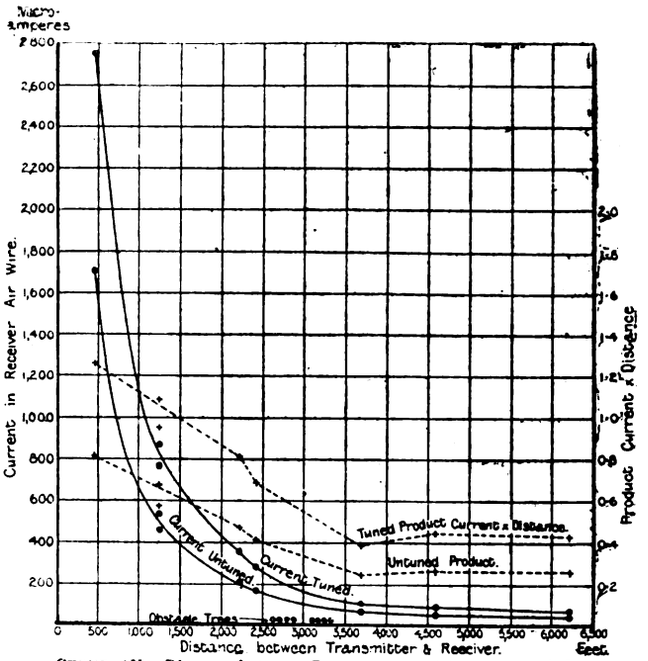
	R.M.S. current.	C²R watts.
Wave No. 1. Mercury interrupter	0 36	7·8
,, ,, 2. ,, ,,	0·486	14·2
,, ,, 3. ,, ,,	0·5	15·0

The greatest proportion of this energy picked up by the receiver was about one six-hundredth part at a distance of 100ft., and the smallest proportion somewhat less than one six-millionth part at a distance of 7,475ft. For the different waves the power used in the whole primary circuit of the transmitting apparatus varied between 100 and 200 watts roughly, so that only a small percentage of the applied energy was converted into useful oscillations in the radiating system.



CURVES III.—Distance between Transmitter and Receiver varied. Full lines Grisson Interrupter. Dotted lines Mercury Interrupter. Receiver in Paddock, Position A on Map.

Distance between Transmitter and Receiver Varied.—All the conditions at both the transmitting and receiving stations were kept as far as possible constant, and the distance between the two stations was altered by moving the transmitter. The successive positions of the transmitter are indicated on the map (Fig. 2). It was found impossible to get exactly the same current in the transmitter air wire at the different positions of the transmitter, keeping the spark-length fixed. With the mercury interrupter



CURVES IV.—Distance between Transmitter and Receiver varied. Receiver near Fish Ponds, Position B on Map.

the current varied ± 1 per cent. from the mean, and with the Grisson interrupter ± 1¾ per cent. in the first set of experiments (Table V. and Curve III.). In the second and third sets of experiments (Table VI. and Curves IV. and V.) the variations were much greater. Owing to the influence of screening and obstacles it is impossible to say what the law connecting received current with distance actually is, but a consideration of the curves obtained by forming the product of the received current multiplied by the distance and plotting this product

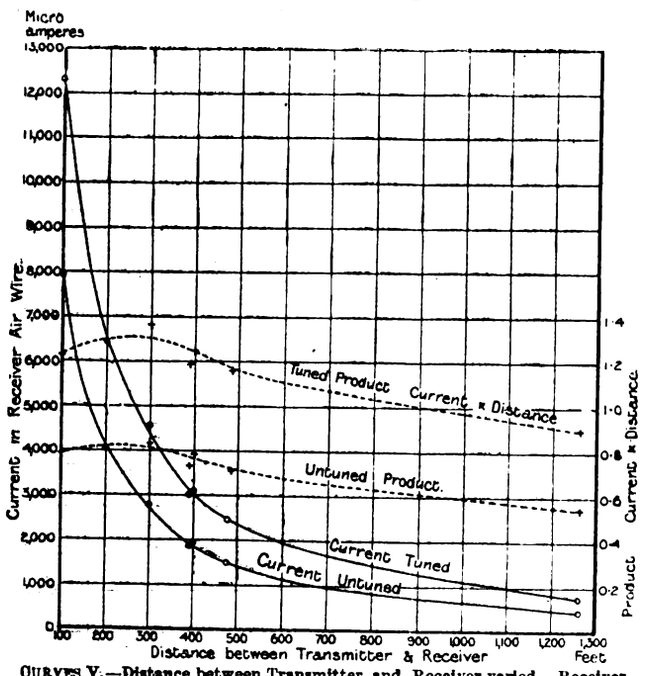
against distance, indicates that in these tests the current has decreased in general rather more rapidly than inversely as the distance with increasing distances, though nowhere near so rapidly as inversely as the square of the distance.



CURVES V.—Distance between Transmitter and Receiver varied. Receiver near Fish Ponds, Position B on Map. Short Range Tests.

The effect of the obstacles, the trees, is very well shown in the product curves as well as the improvement in the conditions when the transmitter gets out in the open again from being directly behind an obstacle. The curves given clearly indicate that at close quarters the rate of decrease is much more rapid than at greater distances. Within the wave-length distance there is a very rapid decrease, which tapers off to a more uniform rate at about three wave-lengths in the case of the longest wave used in the experiments. For the shorter waves the results obtained were not so regular, but an approximately similar law holds.

(To be continued.)

PERSONAL.

Mr. W. Fennell has been appointed manager of the Wednesbury electricity undertaking at a salary of £180 per annum.

The President of the Board of Education has (temporarily) appointed Mr. S. Herbert Cox to the professorship of mining at the Royal School of Mines, South Kensington, vacant by the death of Sir Clement le Neve Foster. Mr. Cox was president of the Institution of Mining and Metallurgy in 1899-1900.

The Johannesburg Council has appointed Mr. J. A. McMullen station engineer.

The Yarmouth Town Council have increased the salary of Mr. F. L. Turner, tramways manager, from £180 to £230, and by annual increments of £10 to reach a maximum of £250.

We understand that Mr. W. A. Walker, chief assistant electrical engineer to the Kettering Urban District Council, has been appointed electrical engineer, in place of Mr. F. G. Bakewell, resigned.

Mr. D. P. Thomson has resigned his position as chief designer of the continuous-current section of the British Thomson-Houston Co., Rugby, in order to accept a post with the General Electric Co., of Schenectady, N.Y. Before leaving he was made the recipient of various presentations, including a complete set of Dickens's works and a cheque from the office staff, and a set of cutlery from the works offices.

DUDLEY ELECTRICITY ACCOUNTS.

The accounts of the Dudley Corporation electricity department for the year ended March 31, 1905, show a total expenditure on capital account of £77,562. Appended are abstracts of the revenue account, balance-sheet, and statement of electricity generated, sold, etc.

REVENUE ACCOUNT.

THE PACIFIC CABLE CONFERENCE.

The report of the Pacific Cable Conference, 1905, which is signed by the Right Hon. A. Lyttleton, M.P., Lord Jersey, Sir William Mulock, and Sir Sandford Fleming, was issued last week as a parliamentary paper. From the appended text of the report the reader will observe that the committee consider the agreement between the Commonwealth Government and the Eastern Extension Telegraph Company should be amended before it is ratified so as to make it terminable in 1913.

In approaching the consideration of the questions referred to us in connection with the working of the Pacific cable, we have endeavoured to bear in mind that this enterprise was initiated, not merely as a commercial undertaking, but also and largely, for the purpose of promoting Imperial unity. We have deemed it of special importance that this, the first joint commercial enterprise promoted by the various self-governing States of the Empire, should be carried through with success, and have, therefore, aimed at removing all sources of friction between the partner governments, and have sought to accommodate such difficulties as have arisen in the spirit of reasonable compromise.

2. We find from statistics furnished by the Eastern Extension Telegraph Company and the Pacific Cable Board, which are summarised in the appendix to this report, that in the case of New Zealand and all the States of Australia, except New South Wales and Victoria, the Pacific Cable obtained approximately in the years 1903 and 1904 the share of the total traffic between Australasia and the United Kingdom, which was anticipated at the time when it was decided to lay the cable; but that in the case of the two colonies of New South Wales and Victoria the Pacific Cable has obtained a much smaller proportion of traffic than was anticipated; and we consider that this result must be attributed mainly if not entirely to the fact that the telegraph company has been granted special wires and has been allowed to open offices in Sydney and Melbourne under the New South Wales Agreement of Jan. 16, 1901, and the Commonwealth Agreement of June 8, 1903.

3. We do not think that any useful purpose would be served at the present time by discussing the action of the New South Wales Government in entering into the above-mentioned agreement, but it is sufficient to observe that when the Commonwealth Government took over the administration of the Postal and Telegraph Departments of the various States of Australia they found this agreement in existence, and considered themselves bound to recognise and carry it out, unless it could be varied by mutual arrangement between the Government and the company. Accordingly negotiations to that end were entered into, and with a view to the immediate termination of the New South Wales agreement and of certain agreements with other States it was agreed that concessions should be made to the company throughout all Australia, but for a limited term of years only.

4. This Commonwealth agreement was made subject to the approval of the Parliament of the Commonwealth, to be evidenced either by Act of Parliament or by the passing of resolutions affirming the agreement in and by each House. Such a resolution was passed by the House of Representatives on July 29, 1903, and was communicated to the Senate with a request for its concurrence therein. The Senate, after discussing the agreement at several sittings, finally adjourned the ratification on Sept. 8, 1903, with the object of securing that the whole matter should first be discussed at a conference between representatives of the Governments who are partners in the Pacific Cable, and the Commonwealth Government agreed in the following month that such a conference should be held, but owing to various unavoidable causes the conference could not be assembled until June, 1905. In the meantime the Australian Government allowed effect to be given to the agreement by permitting the company to open an office in Melbourne and giving them a special wire to that city.

5. The Commonwealth Government represents that their agreement is more favourable to the interests of the Pacific cable than the New South Wales agreement, inasmuch as the latter was one of indefinite duration, while the former can be terminated after a certain date by giving two years' notice in writing; but we consider it of the utmost importance that the date of the termination of the agreement should be settled now and not be left for decision in 1913.

6. Sir E. Barton claimed, in his letter to Mr. Seddon of June 1, 1903, that "by reducing the term of the agreement to a reasonable period, the Commonwealth has obtained for the Pacific Cable a very great advantage, which cannot fail to be of immense and increasing value," but we feel that this advantage is not definitely secured so long as any doubt remains whether the agreement will or will not be actually terminated after it has been in operation for 10 years. We, therefore, earnestly trust that the Commonwealth Parliament will not ratify the agreement unless Clause 25 is amended so as to read, "this agreement shall remain in force until Oct. 31, 1913, and no longer." The partners in the Pacific Cable will then be restored to the position in which they stood prior to the making of the New South Wales agreement, and will then be free to determine their policy unhampered by any agreements arrived at by any of the Governments without previous consultation with the other partners.

7. We are advised that the recital in the preamble of the Commonwealth agreement, that it is desirable to substitute one agreement for certain other agreements, including the New South Wales agreement and the similar agreement with South Australia, Western Australia, and Tasmania, cannot safely be relied upon to prevent the revival of those agreements on the termination of the Commonwealth agreement. We, therefore, think that an express provision, excluding such revival, should have been inserted in the Commonwealth agreement, and we trust that such a provision will be inserted before the agreement is ratified.

8. We understand, from statements made by Sir E. Barton in the House of Representatives on the occasion of the ratification by that House of the Commonwealth agreement, that the Commonwealth Government has undertaken to grant the Pacific cable equal facilities with the Eastern Extension Telegraph Company without any qualification, as soon as they are required. We consider that the Pacific Cable Board should forthwith be given such facilities and that the Board should take steps to secure the largest possible amount of Australian traffic by all legitimate methods of business competition. This would, of course, involve the Board in very considerable expense in connection with local offices and with advertising and canvassing, and we think it might be left to the discretion of the Pacific Cable Board to negotiate an amicable arrangement with the Eastern Extension Telegraph Company provided that no arrangement be finally concluded without the approval of the Governments concerned, nor unless the Commonwealth agreement is amended in the manner above suggested.

9. It has been suggested that the Commonwealth Government should reduce their terminal rate to the level of the rate for urgent internal messages. The majority of us are of opinion that the rate of 5d. per word is excessive, and we trust that the Government will see their way to reduce it.

10. We note that the Australian Government have undertaken to remit all customs duties and other charges (as specified in Clause 19 of the Commonwealth agreement with the Eastern Extension Telegraph Company), which have been or shall be levied on the Pacific Cable Board, and we hope that the Dominion Government will adopt a similar course.

11. In conclusion we desire to recommend, with a view not only to the prevention of any misunderstanding, but also to the maintaintenance of cordial and friendly relations between the Governments in respect of the Pacific Cable, that should any question hereafter arise in connection with terminal rates, or customs duties, or proposed concessions or privileges to any cable or telegraph company, or respecting any other matters likely to affect the interests of the Pacific Cable, such question should be referred to the Pacific Cable Board and the various Governments concerned for consideration before any final action is taken upon it.

12. The Pacific Cable being the first enterprise of the kind undertaken by a number of British Governments in partnership, it need occasion no surprise if at the commencement of the enterprise some questions should have arisen touching the obligations of the various partner governments towards the common undertaking, but inasmuch as they fully appreciate the far-reaching political consequences attendant on the success or failure of the Pacific Cable, we feel assured that the fullest possible effect will be given to the foregoing recommendations and suggestions which we respectfully submit for the consideration of His Majesty's Government and the Governments of Canada, Australia, and New Zealand.

The traffic statistics appended show a grand total of 2,784,220 words in 1904 (Eastern 1,889,359 and Pacific Cable 894,861), as compared with 2,636,357 words in 1903 (Eastern 1,824,397 and Pacific Cable 811,960).

TRADE NOTICES AND NOVELTIES.

Ferranti Single-Phase Transformers.

The accompanying illustration (Fig. 1) represents a Ferranti 30-kw., 2,000-volt, single-phase power transformer of a design which is the outcome of the company's long experience. The magnetic circuit of this transformer is of the core type, the sheet steel used in its construction being selected for its low hysteresis loss and freedom from ageing effect. Prolonged tests have shown that the loss due to hysteresis in this metal does not increase with time. The construction of the core is shown in Fig. 2. The joints are imbricated, and the core is held between brass clamp plates secured by bolts. The yokes

Digitized by Google

are pressed between cast-iron yoke plates and the whole transformer supported between top and bottom plates by means of steel hanging bolts. The mechanical construction is thus very strong, while the electrical design results in good regulation. The drop on inductive load is kept low by sandwiching the windings—that is to say, the primary winding is partly inside and partly outside the secondary. Another point worthy of note is that the maximum efficiency is arranged to be at three-quarter load, this being thought the most suitable for the

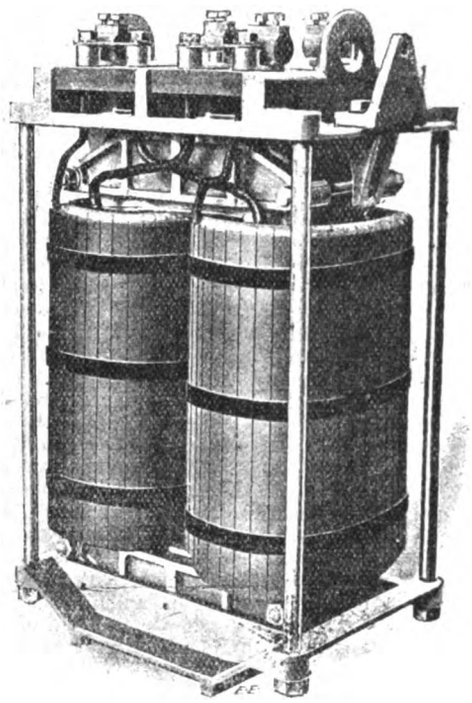

FIG. 1—Ferranti Single-Phase Transformer.

majority of electricity supply works. Particular care is also taken to secure ample cooling surface, air ducts being left between all the coils and between the coils and core, so that the otherwise inaccessible interior parts are efficiently ventilated. A maximum temperature rise of 45deg. C. above the surrounding atmosphere after a full-load run of eight hours is guaranteed. Transformers of similar design and construction are made by Messrs. Ferranti, Limited, in eight standard sizes, ranging in output from 50 kw. to 2½ kw., for four voltages—viz.: not exceeding 2,500 volts, 5,000 volts, 7,500 volts, and 10,000 volts respectively. They can all be contained in the firm's standard patterns of ventilated covers, sub-station tanks, street

tanks, or simple watertight tanks, provided with glands for the cables as may be desired.

The "Ratqua" Rail Anchors.

Illustrations are given herewith of the "Ratqua" rail anchors. These anchors are made in two types. No. 1 consists of a foundation plate in the form of an H-iron, the top flange of which at one end is turned up and over to make a forked grip on the bottom flange of the girder rail, and at the other end is slotted to take the fork of the "locking plate." This latter is formed so as to fit the outside of the girder rail, and when "locked" into the slot of the H-iron, is bolted with a single bolt to the web of the rail. No. 2 consists of a foundation plate in the form of an H-iron, the top flange of which is slotted at both ends. It carries two "locking plates," one on either side of the rail, both of which are bolted up to web of rail by a single bolt. This type of anchor is favoured by some engineers owing to the extra stiffness it gives to web of rail. As in the case of "No. 1," the tighter the "locking plates" are bolted up the tighter the grip of anchor on rail. It is claimed that both these types of anchor enable a rail to be taken out and replaced by simply removing the "locking plates," which operation in no way disturbs or shakes the H-iron plate in the concrete foundation. Moreover, the bolts are accessible, and not buried in concrete. In new track it has been found from actual experience that four anchors to each 45ft. length of rail are sufficient to prevent "pumping"—that is to say, one at 2ft. 6in. from each end of rail, and the other two at a distance of 13ft. 4in. apart centre to centre. The "Ratqua No. 2" anchor is specially recommended for use on an existing track which has been laid without anchors, and is

showing signs of pumping. Messrs. Hurst, Nelson, and Co., Limited, Motherwell, are the sole manufacturers. We are indebted to the "Ratqua" Rail Anchors, 4, Victoria-terrace, Edinburgh, for the above particulars.
